$$\frac{\mathbf{y}^*\mathbf{E}\mathbf{x}_0}{\mathbf{y}^*\mathbf{x}_0} = \frac{c\,\mathbf{y}^*\mathbf{E}\mathbf{x}}{c\,\mathbf{y}^*\mathbf{x}} = \frac{\mathbf{y}^*\mathbf{E}\mathbf{x}}{\mathbf{y}^*\mathbf{x}},$$

by the algebra of limits, the denominator's limit being non-zero. This proves (c).

■

No implicit function theorem was needed. The usual textbook route to this formula differentiates $\det(z\mathbf{I} - \mathbf{A} - t\mathbf{E}) = 0$ implicitly, which presupposes that a differentiable solution $z = \lambda(t)$ exists; that is the implicit function theorem, a piece of analysis this book has not imported. The proof above needed only the continuity of Corollary 15.7.4 and the fact that the adjugate writes down an eigenvector whose entries are polynomials. The analysis consists of limits of polynomials, which is the algebra of limits.

> *Remark.* Since $\lambda(s)$ is a simple eigenvalue of $\mathbf{A} + s\mathbf{E}$ for every $|s| < t_0$, the theorem applies again at $\mathbf{A} + s\mathbf{E}$ in place of $\mathbf{A}$. The eigenvalue it isolates there is $\lambda(s + h)$ for small h, by the uniqueness in (a). So λ is differentiable on the whole interval $(-t_0, t_0)$, with $\lambda'(s) = \mathbf{y}_s^* \mathbf{E} \mathbf{x}_s / (\mathbf{y}_s^* \mathbf{x}_s)$ for right and left eigenvectors $\mathbf{x}_s, \mathbf{y}_s$ of $\mathbf{A} + s\mathbf{E}$ for $\lambda(s)$. We need only $s = 0$.

The formula has a transparent special case. If $\mathbf{A}$ is Hermitian, then $\mathbf{A}^*\mathbf{x} = \mathbf{A}\mathbf{x} = \lambda\mathbf{x}$ with λ real, so $\mathbf{x}$ is also a left eigenvector and we may take $\mathbf{y} = \mathbf{x}$:

$$\lambda'(0) = \frac{\mathbf{x}^* \mathbf{E} \mathbf{x}}{\mathbf{x}^* \mathbf{x}}.$$

When $\mathbf{E}$ is Hermitian too, this is the Rayleigh quotient $R_{\mathbf{E}}(\mathbf{x})$ of Chapter 16 (Definition 16.1.1), which lies in $[\lambda_n(\mathbf{E}), \lambda_1(\mathbf{E})]$ by Proposition 16.1.1. So $|\lambda'(0)| \le \|\mathbf{E}\|_2$ by Lemma 16.3.5, which is the first-order shadow of Weyl's bound $|\lambda_i(\mathbf{A} + \mathbf{E}) - \lambda_i(\mathbf{A})| \le \|\mathbf{E}\|_2$ (Corollary 16.3.6).

> *Quick check.* Let $\mathbf{A} = \operatorname{diag}(d_1, \dots, d_n)$ with distinct d_i, and let $\mathbf{E} = (e_{ij})$ be arbitrary. What is the derivative at $t = 0$ of the eigenvalue of $\mathbf{A} + t\mathbf{E}$ near d_i?

> *Solution.* The eigenvalue d_i is simple, with $\mathbf{x} = \mathbf{e}_i$ and $\mathbf{y} = \mathbf{e}_i$, since $\mathbf{e}_i^* \mathbf{A} = d_i \mathbf{e}_i^*$. So $\lambda'(0) = \mathbf{e}_i^* \mathbf{E} \mathbf{e}_i / (\mathbf{e}_i^* \mathbf{e}_i) = e_{ii}$. To first order, the eigenvalues of a perturbed diagonal matrix with distinct diagonal entries move by the diagonal of the perturbation, and the off-diagonal entries of $\mathbf{E}$ enter only at second order.

19.11.3 The condition number of a simple eigenvalue

The derivative $\mathbf{y}^*\mathbf{E}\mathbf{x}/(\mathbf{y}^*\mathbf{x})$ depends on the direction $\mathbf{E}$. To measure how sensitive λ itself is, bound it over all directions of a given size. By Cauchy–Schwarz and the definition of $\|\mathbf{E}\|_2$,

$$|\lambda'(0)| = \frac{|\mathbf{y}^*\mathbf{E}\mathbf{x}|}{|\mathbf{y}^*\mathbf{x}|} \le \frac{\|\mathbf{y}\|\,\|\mathbf{E}\mathbf{x}\|}{|\mathbf{y}^*\mathbf{x}|} \le \frac{\|\mathbf{x}\|\,\|\mathbf{y}\|}{|\mathbf{y}^*\mathbf{x}|}\,\|\mathbf{E}\|_2.$$

The factor in front of $\|\mathbf{E}\|_2$ depends on $\mathbf{A}$ and λ only. It recurs in every estimate below, so we give it a name.

The condition number of an eigenvalue is the largest factor by which a perturbation of the matrix can move that eigenvalue, to first order.

Definition 19.11.1 — Condition Number of a Simple Eigenvalue

Let $\mathbf{A} \in M_n(\mathbb{C})$ and let λ be a **simple** eigenvalue of $\mathbf{A}$, with a right eigenvector $\mathbf{x}$ and

a left eigenvector $\mathbf{y}$, so $\mathbf{y}^*\mathbf{A} = \lambda\mathbf{y}^*$. The **condition number** of λ is

$$\kappa_{\mathbf{A}}(\lambda) := \frac{\|\mathbf{x}\|\,\|\mathbf{y}\|}{|\mathbf{y}^*\mathbf{x}|}.$$

In words: take any right eigenvector and any left eigenvector for λ, multiply their lengths, and divide by the modulus of their inner product. The definition is made only for a **simple** eigenvalue, which is what makes the denominator non-zero (Lemma 19.11.1 (b)). It is also what makes the number well defined: by part (a) of the lemma, any other choice is $\alpha\mathbf{x}$ and $\beta\mathbf{y}$ with $\alpha, \beta \neq 0$, and then

$$\frac{\|\alpha\mathbf{x}\|\,\|\beta\mathbf{y}\|}{|(\beta\mathbf{y})^*(\alpha\mathbf{x})|} = \frac{|\alpha|\,|\beta|\,\|\mathbf{x}\|\,\|\mathbf{y}\|}{|\overline{\beta}\alpha|\,|\mathbf{y}^*\mathbf{x}|} = \kappa_{\mathbf{A}}(\lambda).$$

The subscript $\mathbf{A}$ and the argument λ are part of the notation. They keep $\kappa_{\mathbf{A}}(\lambda)$ apart from the condition number $\kappa(\mathbf{A}) = \|\mathbf{A}\|\|\mathbf{A}^{-1}\|$ of a matrix (Definition 15.8.1).

Examples.

- **A 1×1 matrix.** For $\mathbf{A} = (a)$ the eigenvalue a is simple, with $x = y = 1$, so $\kappa_{\mathbf{A}}(a) = 1$. This is the degenerate case, and it is the right answer: the eigenvalue of $(a + te)$ is $a + te$, which moves exactly as fast as the matrix.
- **A diagonal matrix with distinct entries.** For d_i, the Quick check above found $\mathbf{x} = \mathbf{y} = \mathbf{e}_i$, so $\kappa_{\mathbf{A}}(d_i) = 1$. Every eigenvalue is perfectly conditioned.
- **A triangular 2×2.** For $\mathbf{A} = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 2 \end{smallmatrix}\right)$ and the eigenvalue 1, the Quick check after the lemma found $\mathbf{x} = \mathbf{e}_1$ and $\mathbf{y} = (1, -1)$, with $\mathbf{y}^*\mathbf{x} = 1$. So $\kappa_{\mathbf{A}}(1) = 1 \cdot \sqrt{2}/1 = \sqrt{2}$. The single off-diagonal entry has made the eigenvalue somewhat more sensitive.

Non-example by minimal change. Change the entry 2 of the last example to $1 + s$, and let $s \to 0$. For real $s \neq 0$ the matrix $\mathbf{B}_s = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1+s \end{smallmatrix}\right)$ has the simple eigenvalue 1, with $\mathbf{x} = \mathbf{e}_1$ and $\mathbf{y} = (s, -1)$, so $\kappa_{\mathbf{B}_s}(1) = \sqrt{1 + s^2}/|s|$. At $s = 0$ the matrix is $\mathbf{J}_2(1)$, and the eigenvalue 1 is no longer simple. The right and left eigenvectors still exist, $\mathbf{e}_1$ and $\mathbf{e}_2$, but $\mathbf{y}^*\mathbf{x} = 0$, so the clause "simple" fails and the quotient is undefined. The formula for $s \neq 0$ shows that it blows up on the way.

Why this definition. Three choices in it can be checked.

- **Both lengths go in the numerator.** This makes $\kappa_{\mathbf{A}}(\lambda)$ independent of the scaling of $\mathbf{x}$ and $\mathbf{y}$, as just computed. A normalization such as $\mathbf{y}^*\mathbf{x} = 1$ alone would leave one length free.
- **The norm is the Euclidean one,** because then the bound $|\lambda'(0)| \leq \kappa_{\mathbf{A}}(\lambda)\|\mathbf{E}\|_2$ above is attained by some $\mathbf{E}$, as part (b) of the proposition below shows. So $\kappa_{\mathbf{A}}(\lambda)$ is the exact worst case, not merely an upper bound. The same number is also the worst case over $\|\mathbf{E}\|_F = 1$: the bound survives because $\|\mathbf{E}\|_2 \leq \|\mathbf{E}\|_F$ (Proposition 15.3.4), and the extremal $\mathbf{E}$ has rank one, so its two norms agree by the same proposition.
- **The name** matches Definition 15.8.1. There, $\kappa(\mathbf{A})$ is the worst factor by which $\mathbf{A}$ magnifies a relative error in $\mathbf{b}$ into a relative error in the solution of $\mathbf{A}\mathbf{x} = \mathbf{b}$. Here $\kappa_{\mathbf{A}}(\lambda)$ is the worst factor by which a change in the matrix is magnified into a change in one eigenvalue, to first order.

Warning. **A condition number is a first-order statement, not a bound.** It governs $\lambda(t)$ only for small t, through $\lambda(t) - \lambda = t\lambda'(0) + \rho(t)$, and the remainder $\rho(t)$ can be as large as the first-order term while $t\|\mathbf{E}\|_2$ still looks small. Take $\mathbf{A} = \left(\begin{smallmatrix} 1 & M \\ 0 & 2 \end{smallmatrix}\right)$ with $M > 0$, for which $\kappa_{\mathbf{A}}(1) = \sqrt{1 + M^2}$, as the worked example below computes, and $\mathbf{E} = \mathbf{E}_{21}$. At $t = -1/(4M)$ the matrix $\mathbf{A} + t\mathbf{E}$ has trace 3 and determinant $2 + \frac{1}{4}$, so

both its eigenvalues equal $\frac{3}{2}$. The eigenvalue 1 has moved by $\frac{1}{2}$, while the first-order prediction is $\kappa_{\mathbf{A}}(1)\,|t|\,\|\mathbf{E}\|_2 = \sqrt{1+M^2}/(4M)$, which is close to $\frac{1}{4}$ for large M. At that point the eigenvalue is no longer simple, and the square root in the exact formula $(3-\sqrt{1+4Mt})/2$ has no derivative there.

The first payoff is a list of properties, which together say what kind of number $\kappa_{\mathbf{A}}(\lambda)$ is.

Proposition 19.11.3 — Properties of the Eigenvalue Condition Number

Let $\mathbf{A} \in M_n(\mathbb{C})$ and let λ be a simple eigenvalue of $\mathbf{A}$ with right eigenvector $\mathbf{x}$ and left eigenvector $\mathbf{y}$.

(a) $\kappa_{\mathbf{A}}(\lambda)$ does not depend on the choice of $\mathbf{x}$ and $\mathbf{y}$, and $\kappa_{\mathbf{A}}(\lambda) \geq 1$, with equality if and only if $\mathbf{y}$ is a multiple of $\mathbf{x}$.

(b) For every $\mathbf{E} \in M_n(\mathbb{C})$, the eigenvalue $\lambda(t)$ of Theorem 19.11.2 satisfies $|\lambda'(0)| \leq \kappa_{\mathbf{A}}(\lambda)\|\mathbf{E}\|_2$. Equality holds for $\mathbf{E} = \mathbf{y}\mathbf{x}^*/(\|\mathbf{x}\|\|\mathbf{y}\|)$, which has $\|\mathbf{E}\|_2 = 1$. Hence $\kappa_{\mathbf{A}}(\lambda) = \max\{|\lambda'(0)| : \|\mathbf{E}\|_2 = 1\}$.

(c) If $\mathbf{A}$ is normal, then $\kappa_{\mathbf{A}}(\mu) = 1$ for every simple eigenvalue μ of $\mathbf{A}$.

(d) If $\mathbf{A} = \mathbf{X}\mathbf{\Lambda}\mathbf{X}^{-1}$ with $\mathbf{X}$ invertible and $\mathbf{\Lambda} = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$, and λ_i is simple, then $\kappa_{\mathbf{A}}(\lambda_i) \leq \kappa_2(\mathbf{X})$.

(e) $\kappa_{\mathbf{A}}(\lambda) = 1/\cos\theta$, where $\theta \in [0, \pi/2)$ is the principal angle between the lines $\operatorname{span}(\mathbf{x})$ and $\operatorname{span}(\mathbf{y})$ (Definition 19.8.1).

Proof.

(a) Independence of the choice was checked after Definition 19.11.1. By Theorem 10.1.5, $|\mathbf{y}^*\mathbf{x}| = |\langle \mathbf{x}, \mathbf{y}\rangle| \leq \|\mathbf{x}\|\|\mathbf{y}\|$, so $\kappa_{\mathbf{A}}(\lambda) \geq 1$, with equality if and only if $(\mathbf{x}, \mathbf{y})$ is linearly dependent, that is, since both are non-zero, if and only if $\mathbf{y}$ is a multiple of $\mathbf{x}$.

(b) The inequality is the display before Definition 19.11.1, with $\lambda'(0)$ given by Theorem 19.11.2 (c). For the equality, put $\mathbf{E} = \mathbf{y}\mathbf{x}^*/(\|\mathbf{x}\|\|\mathbf{y}\|)$. For every $\mathbf{v}$, $\mathbf{y}\mathbf{x}^*\mathbf{v} = (\mathbf{x}^*\mathbf{v})\,\mathbf{y}$, so $\|\mathbf{y}\mathbf{x}^*\mathbf{v}\| = |\langle \mathbf{v}, \mathbf{x}\rangle|\,\|\mathbf{y}\| \leq \|\mathbf{x}\|\|\mathbf{y}\|\|\mathbf{v}\|$ by Cauchy–Schwarz, with equality at $\mathbf{v} = \mathbf{x}$. Hence $\|\mathbf{y}\mathbf{x}^*\|_2 = \|\mathbf{x}\|\|\mathbf{y}\|$ by Definition 15.3.2, and $\|\mathbf{E}\|_2 = 1$. Moreover

$$\mathbf{y}^*\mathbf{E}\mathbf{x} = \frac{(\mathbf{y}^*\mathbf{y})(\mathbf{x}^*\mathbf{x})}{\|\mathbf{x}\|\|\mathbf{y}\|} = \|\mathbf{x}\|\,\|\mathbf{y}\|, \qquad \text{so} \qquad |\lambda'(0)| = \frac{\|\mathbf{x}\|\,\|\mathbf{y}\|}{|\mathbf{y}^*\mathbf{x}|} = \kappa_{\mathbf{A}}(\lambda).$$

The maximum formula restates the inequality and its equality case.

(c) Let $\mathbf{A}\mathbf{x} = \mu\mathbf{x}$ with $\mathbf{x} \neq \mathbf{0}$. By Theorem 11.3.3, $\mathbf{A}^*\mathbf{x} = \overline{\mu}\,\mathbf{x}$, and taking conjugate transposes gives $\mathbf{x}^*\mathbf{A} = \mu\,\mathbf{x}^*$. So $\mathbf{x}$ is also a left eigenvector for μ, and (a) gives $\kappa_{\mathbf{A}}(\mu) = 1$.

(d) Write $\mathbf{x}_i = \mathbf{X}\mathbf{e}_i$ and $\mathbf{y}_i^* = \mathbf{e}_i^*\mathbf{X}^{-1}$. From $\mathbf{A}\mathbf{X} = \mathbf{X}\mathbf{\Lambda}$ and $\mathbf{X}^{-1}\mathbf{A} = \mathbf{\Lambda}\mathbf{X}^{-1}$, column i and row i give $\mathbf{A}\mathbf{x}_i = \lambda_i\mathbf{x}_i$ and $\mathbf{y}_i^*\mathbf{A} = \lambda_i\mathbf{y}_i^*$, and both vectors are non-zero because $\mathbf{X}$ is invertible. Also $\mathbf{y}_i^*\mathbf{x}_i = \mathbf{e}_i^*\mathbf{X}^{-1}\mathbf{X}\mathbf{e}_i = 1$. Now $\|\mathbf{x}_i\| \leq \|\mathbf{X}\|_2\|\mathbf{e}_i\| = \|\mathbf{X}\|_2$ by Theorem 15.3.2 (a). For $\mathbf{y}_i$, Cauchy–Schwarz gives

$$\|\mathbf{y}_i\|^2 = \mathbf{y}_i^*\mathbf{y}_i = \mathbf{e}_i^*\mathbf{X}^{-1}\mathbf{y}_i \leq \|\mathbf{X}^{-1}\mathbf{y}_i\| \leq \|\mathbf{X}^{-1}\|_2\,\|\mathbf{y}_i\|,$$

so $\|\mathbf{y}_i\| \le \|\mathbf{X}^{-1}\|_2$, after dividing by $\|\mathbf{y}_i\| > 0$. Therefore $\kappa_{\mathbf{A}}(\lambda_i) = \|\mathbf{x}_i\|\|\mathbf{y}_i\|/1 \le \|\mathbf{X}\|_2\|\mathbf{X}^{-1}\|_2 = \kappa_2(\mathbf{X})$, by (a) and Definition 15.8.1.

(e) The vectors $\mathbf{x}/\|\mathbf{x}\|$ and $\mathbf{y}/\|\mathbf{y}\|$ are orthonormal bases of the two lines, so by Definition 19.8.1 the single principal angle satisfies $\cos\theta = \sigma_1(c)$, where $c = \mathbf{y}^*\mathbf{x}/(\|\mathbf{x}\|\|\mathbf{y}\|)$ is a 1×1 matrix. Its only singular value is $|c|$, the square root of the eigenvalue $\bar{c}c$ of c^*c (Definition 12.8.1). Hence $\cos\theta = |\mathbf{y}^*\mathbf{x}|/(\|\mathbf{x}\|\|\mathbf{y}\|) = 1/\kappa_{\mathbf{A}}(\lambda)$, which is positive by Lemma 19.11.1 (b), so $\theta < \pi/2$. This proves the proposition.

■

Part (e) is the picture to keep. An eigenvalue is well conditioned when its right and left eigenvectors point in nearly the same direction, and ill conditioned when they are nearly perpendicular. For a normal matrix they coincide, by (c). At a Jordan block they are exactly perpendicular, by the warning after the lemma.

Part (d) places the new number beside §04. Bauer–Fike bounds the movement of every eigenvalue by $\kappa_2(\mathbf{X})\|\mathbf{E}\|_2$, for every size of $\mathbf{E}$. Part (d) says that, to first order, each simple eigenvalue individually does at least as well, with its own constant $\kappa_{\mathbf{A}}(\lambda_i)$, and that constant involves no choice of $\mathbf{X}$. This is the refinement §04's warning promised. The first-order statement is sharper. The Bauer–Fike bound is global and needs no smallness.

19.11.4 A worked example

Upper triangular 2×2 matrices show everything, because their eigenvectors can be written down at once.

Example. (The condition numbers of a triangular 2×2 matrix)

Let $a, b, d \in \mathbb{C}$ with $a \ne d$, and $\mathbf{A} = \left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)$.

(a) Compute $\kappa_{\mathbf{A}}(a)$ and $\kappa_{\mathbf{A}}(d)$.

(b) For $a = 1$, $b = M > 0$, $d = 2$, compare with the smallest value of $\kappa_2(\mathbf{X})$ over all diagonalizing $\mathbf{X}$.

(c) For the same matrix and $\mathbf{E} = \mathbf{E}_{21}$, compute $\lambda'(0)$ for the eigenvalue 1 from Theorem 19.11.2, and compare with the exact eigenvalues of $\mathbf{A} + t\mathbf{E}$ for $M = 100$ and $t = 10^{-4}$.

Solution.

(a) Both eigenvalues are simple, since $a \ne d$. For a: $\mathbf{A}\mathbf{e}_1 = a\mathbf{e}_1$, so $\mathbf{x} = \mathbf{e}_1$. A left eigenvector solves $\mathbf{y}^*(\mathbf{A} - a\mathbf{I}) = \mathbf{0}$, where $\mathbf{A} - a\mathbf{I} = \left(\begin{smallmatrix} 0 & b \\ 0 & d-a \end{smallmatrix}\right)$. For a row $\mathbf{y}^* = (u, v)$ the product is $(0,\ ub + v(d-a))$, so $\mathbf{y}^* = (d-a, -b)$ works. Then $\mathbf{y}^*\mathbf{x} = d - a$, and

$$\kappa_{\mathbf{A}}(a) = \frac{1\cdot\sqrt{|d-a|^2 + |b|^2}}{|d-a|} = \sqrt{1 + \frac{|b|^2}{|a-d|^2}}.$$

For d: $\mathbf{y} = \mathbf{e}_2$ is a left eigenvector, because $\mathbf{e}_2^*\mathbf{A} = (0, d) = d\,\mathbf{e}_2^*$. A right eigenvector is $\mathbf{x} = (b, d-a)$, since $(\mathbf{A} - d\mathbf{I})\mathbf{x} = \big((a-d)b + b(d-a),\ 0\big) = \mathbf{0}$. Then $\mathbf{y}^*\mathbf{x} = d - a$, and $\kappa_{\mathbf{A}}(d)$ is given by the same formula. The two condition numbers are equal. They are large exactly when the off-diagonal entry is large compared with the gap

between the eigenvalues.

(b) Here $\kappa_{\mathbf{A}}(1) = \kappa_{\mathbf{A}}(2) = \sqrt{1+M^2}$. §04 computed κ_2 for two diagonalizing matrices of this $\mathbf{A}$ (Example (A large corner, separated eigenvalues)), and the better one, with unit columns, gave $M + \sqrt{1+M^2}$. We show that no choice does better. The eigenvectors are the multiples of $\mathbf{e}_1$ and of $(M, 1)$, and the columns of a diagonalizing $\mathbf{X}$ are eigenvectors (Theorem 8.4.1). So, up to the order of its columns, which does not change $\kappa_2(\mathbf{X})$, every diagonalizing $\mathbf{X}$ has the form $\mathbf{X} = \left(\begin{smallmatrix} \alpha & \beta M \\ 0 & \beta \end{smallmatrix}\right)$ with $\alpha, \beta \neq 0$, by Lemma 19.11.1 (a). Multiplying $\mathbf{X}$ by a scalar does not change $\kappa_2(\mathbf{X})$, so we may take $\alpha = 1$. Let $\sigma_1 \geq \sigma_2 > 0$ be the singular values of $\mathbf{X}$. They are the square roots of the eigenvalues of $\mathbf{X}^*\mathbf{X}$ (Definition 12.8.1), so $\sigma_1^2\sigma_2^2 = \det(\mathbf{X}^*\mathbf{X}) = |\det \mathbf{X}|^2$, giving $\sigma_1\sigma_2 = |\beta|$, and $\sigma_1^2 + \sigma_2^2 = \operatorname{tr}(\mathbf{X}^*\mathbf{X}) = 1 + |\beta|^2(1+M^2)$. With $k = \kappa_2(\mathbf{X}) = \sigma_1/\sigma_2$,

$$k + \frac{1}{k} = \frac{\sigma_1^2 + \sigma_2^2}{\sigma_1\sigma_2} = \frac{1}{|\beta|} + |\beta|(1+M^2) \geq 2\sqrt{1+M^2},$$

by the inequality $u + v \geq 2\sqrt{uv}$ for $u, v > 0$, with equality exactly when $|\beta| = 1/\sqrt{1+M^2}$, that is, when both columns of $\mathbf{X}$ are unit vectors. The function $k \mapsto k + 1/k$ is increasing for $k \geq 1$, so the smallest possible $\kappa_2(\mathbf{X})$ is the root $k \geq 1$ of $k + 1/k = 2\sqrt{1+M^2}$, namely

$$\min_{\mathbf{X}} \kappa_2(\mathbf{X}) = M + \sqrt{1+M^2}.$$

Indeed $(M + \sqrt{1+M^2})^{-1} = \sqrt{1+M^2} - M$, and the two add up to $2\sqrt{1+M^2}$. So the per-eigenvalue constant $\sqrt{1+M^2}$ is smaller than the best Bauer–Fike constant, by a factor that tends to 2 as M grows, in agreement with Proposition 19.11.3 (d).

(c) With $\mathbf{x} = \mathbf{e}_1$ and $\mathbf{y}^* = (1, -M)$ from (a), $\mathbf{y}^*\mathbf{E}_{21}\mathbf{x} = \mathbf{y}^*\mathbf{e}_2 = -M$ and $\mathbf{y}^*\mathbf{x} = 1$, so

$$\lambda'(0) = -M, \qquad |\lambda'(0)| = M \leq \sqrt{1+M^2}\,\|\mathbf{E}_{21}\|_2 = \kappa_{\mathbf{A}}(1)\,\|\mathbf{E}\|_2.$$

Exactly: $\mathbf{A} + t\mathbf{E} = \left(\begin{smallmatrix} 1 & M \\ t & 2 \end{smallmatrix}\right)$ has trace 3 and determinant $2 - Mt$, so its eigenvalues are

$$\lambda_{\pm}(t) = \frac{3 \pm \sqrt{1+4Mt}}{2},$$

and the one near 1 is $\lambda_-(t)$. For $M = 100$ and $t = 10^{-4}$ we get $4Mt = 0.04$, and $\lambda_-(t) = (3 - \sqrt{1.04})/2 \approx 0.990098$. The eigenvalue has moved by about 0.0099, and the first-order prediction $|t\lambda'(0)| = Mt$ is 0.01. Differentiating $\lambda_-(t)$ directly gives $\lambda_-'(0) = -\frac{1}{4} \cdot 4M = -M$, as the theorem says.

§04 set this matrix beside Chapter 11's Example (A perturbation that moves the eigenvalues a thousand times as far), which perturbed the same corner of $\left(\begin{smallmatrix} 1 & M \\ 0 & 1 \end{smallmatrix}\right)$. There the diagonal entries are equal, and the eigenvalue 1 moved by $\sqrt{Mt}$; with $M = 100$ and $t = 10^{-4}$ that is 0.1, ten times the movement found in (c). The derivative explains the difference. With a gap of 1 between the eigenvalues, the movement is linear in t to first order, with slope M, at most $\kappa_{\mathbf{A}}(1) = \sqrt{1+M^2}$. With no gap there is no derivative at all. Chapter 11's closing remark, that a matrix with well-separated eigenvalues and a large defect behaves less dramatically, is now a formula.

19.11.5 When eigenvalues coalesce

The two computations just compared are the ends of a single family. Put

$$\mathbf{A}_s = \begin{pmatrix} 1 & M \\ 0 & 1+s \end{pmatrix} \qquad (M > 0,\ s > 0).$$

By Example (The condition numbers of a triangular 2×2 matrix) (a), with $b = M$ and $a - d = -s$,

$$\kappa_{\mathbf{A}_s}(1) = \kappa_{\mathbf{A}_s}(1+s) = \sqrt{1 + \frac{M^2}{s^2}} \longrightarrow \infty \qquad (s \to 0^+).$$

As the two eigenvalues move together, the left eigenvector $(s, -M)$ of the eigenvalue 1 turns towards $\mathbf{e}_2$, perpendicular to the right eigenvector $\mathbf{e}_1$. At $s = 0$ the matrix is a Jordan block in disguise, as Chapter 11 observed, the product $\mathbf{y}^*\mathbf{x}$ is 0, and the derivative no longer exists. Instead the eigenvalue moves by $\sqrt{Mt}$ (Example (A perturbation that moves the eigenvalues a thousand times as far)), the case $n = 2$ of the n-th root behavior of §03 (Example (The Jordan block meets Elsner's bound)).

So the first-order theory and the Hölder behavior of §03 are not two separate phenomena. In this family a large condition number is the sign of a nearby coalescence. Near such a coalescence, the linear regime $|\lambda(t) - \lambda| \approx \kappa|t|\|\mathbf{E}\|_2$ holds only for smaller and smaller t, and beyond it the square root takes over. The warning above showed the same thing from the other side: for $\left(\begin{smallmatrix} 1 & M \\ 0 & 2 \end{smallmatrix}\right)$, a perturbation of size $1/(4M)$, about $1/(4\kappa)$, is enough to make the two eigenvalues collide.

> *Remark.* This completes the thread that Chapter 9 §03 started when it warned that the Jordan form is not stable and said that "Chapter 19 returns to this point". §03 measured the instability, a movement of $\varepsilon^{1/n}$ for a block of size n, and showed that the exponent is the worst possible (Example (The Jordan block meets Elsner's bound), Theorem 19.3.3). §04 bounded it for every matrix, with an m-th root for a largest block of size m (Theorem 19.4.5). This section adds the first-order view. A **defective** eigenvalue, one with a Jordan block of size $m \geq 2$, has no finite condition number in any sense: along $\mathbf{J}_m(\lambda) + t\mathbf{E}_{m1}$ every eigenvalue satisfies $|\lambda(t) - \lambda|/|t| = |t|^{1/m-1}$, which is unbounded as $t \to 0$. Any defective eigenvalue inherits this by similarity: if $\mathbf{A} = \mathbf{S}\mathbf{J}\mathbf{S}^{-1}$ with $\mathbf{J}$ in Jordan form (Theorem 9.3.1) and $\mathbf{E} = \mathbf{S}\mathbf{E}'\mathbf{S}^{-1}$, where $\mathbf{E}'$ carries a single 1 in the lower-left corner of a block $\mathbf{J}_m(\lambda)$ and zeros elsewhere, then $\mathbf{A} + t\mathbf{E}$ is similar to $\mathbf{J} + t\mathbf{E}'$, so among its eigenvalues are the m roots of $(z - \lambda)^m = t$, at distance $|t|^{1/m}$ from λ. And, as the family $\mathbf{A}_s$ shows, simple eigenvalues that are about to merge into such a block have condition numbers that blow up. A multiple eigenvalue that is **not** defective is different. For $\mathbf{A} = \mathbf{I}_2$, every eigenvalue of $\mathbf{I}_2 + t\mathbf{E}$ lies within $|t|\|\mathbf{E}\|_2$ of 1 by Corollary 19.4.3 (a), so nothing is infinite. What fails there is only the numbering: the two eigenvalues of $\mathbf{I}_2 + t\mathbf{E}$ cannot in general be told apart as "the one that came from 1", so Definition 19.11.1 does not apply.

19.11.6 Summary and transfer

The chapter set out to answer four questions about a perturbed matrix $\mathbf{A} + \mathbf{E}$: where its eigenvalues are, how far they move, which one goes where, and what happens to eigenvectors, invariant subspaces, singular values and polar factors.

- **Where.** Gershgorin's discs (§01) and the other inclusion regions (§02) locate the eigenvalues without computing any of them.

- **How far.** The continuity of roots (§03) is now a theorem of the book, proved by compactness. It comes with Elsner's Hölder bound, whose exponent $1/n$ cannot be improved, and with a matching version of that bound. Bauer–Fike (§04) replaces the exponent by 1 for diagonalizable matrices, at the price of the factor $\kappa_2(\mathbf{X})$.
- **Which goes where.** Hoffman–Wielandt (§05) matches the eigenvalues of two normal matrices in the Frobenius norm.
- **Hermitian matrices** (§06) got sharper tools: residual bounds, a quadratic bound for the Rayleigh quotient, and relative bounds under congruence.
- **Eigenvectors and subspaces.** The Sylvester equation (§07) and principal angles (§08) together give Davis–Kahan (§09): an invariant subspace moves by at most the perturbation divided by the gap.
- **Singular values and polar factors** (§10) follow by the dilation and by the Sylvester bounds.
- **To first order.** This section gave each simple eigenvalue its own derivative and condition number.

Nine moves did the work.

- **Dominant coordinate plus the triangle inequality.** Look at the row of the eigen-equation where the eigenvector is largest (§01), or at the two largest coordinates (§02). *Transfer:* to locate an eigenvalue without computing it, read the eigen-equation at the coordinate where the eigenvector peaks. There the eigenvalue cannot hide behind the other terms.
- **A determinant bounded two ways.** The product of the distances from μ to the eigenvalues of $\mathbf{A}$ is $|\det(\mathbf{A}-\mu\mathbf{I})|$, and Hadamard's inequality bounds that determinant by column lengths (§03, Elsner). *Transfer:* when a product of unknown quantities is a determinant, bound the determinant from above and the product from below, and read off the smallest factor.
- **Compactness plus uniqueness.** Roots are bounded, so a subsequence of root vectors converges. Its limit is a root vector of the limit polynomial, and unique factorization says which one (§03). *Transfer:* to prove that a solution depends continuously on the data, bound the solutions, extract a convergent subsequence, and let uniqueness of the limiting solution do the rest.
- **An integer-valued continuous function is constant.** Deform $\mathbf{A}$ to its diagonal, and count the eigenvalues in a region whose boundary no eigenvalue crosses (§03, the counting theorem). *Transfer:* to count objects that move continuously, move to a case where the count is obvious, along a path that never lets one of them escape.
- **Factor out the resolvent.** Write $\mathbf{A}+\mathbf{E}-\mu\mathbf{I} = (\mathbf{A}-\mu\mathbf{I})\big(\mathbf{I}+(\mathbf{A}-\mu\mathbf{I})^{-1}\mathbf{E}\big)$, so that the Neumann series makes the second factor invertible whenever $\|(\mathbf{A}-\mu\mathbf{I})^{-1}\mathbf{E}\| < 1$ (§04). *Transfer:* to show a perturbed matrix is invertible, factor out the unperturbed one and ask whether what remains is close to $\mathbf{I}$.
- **Birkhoff turns a doubly stochastic weight into a permutation.** The weights $|w_{ij}|^2$ of a unitary matrix form a doubly stochastic matrix, and a linear function on those attains its minimum at a permutation matrix (§05). *Transfer:* to optimize over matchings, relax to doubly stochastic matrices. A linear objective has its optimum at a vertex, and the vertices are the matchings.
- **The perturbation of a subspace is a Sylvester equation.** The block that couples the old invariant subspace to the new complement satisfies $\widetilde{\mathbf{\Lambda}}_2\mathbf{X} - \mathbf{X}\mathbf{\Lambda}_1 =$ (a piece of $\mathbf{E}$), so the separation of the two spectra is the conditioning (§07, §09). *Transfer:* to measure how far an invariant subspace moves, write down the coupling block and recognize the equation it solves.
- **The singular-pair trick.** Test a matrix equation against the top singular pair of the

unknown $\mathbf{X}$. This turns $\|\mathbf{X}\|_2$ into a scalar that the hypotheses bound directly (§07, used twice in §10). *Transfer:* to bound the spectral norm of the solution of a linear matrix equation, evaluate the equation at the vectors where that norm is attained.

- **The adjugate as a polynomial eigenvector.** A column of $\operatorname{adj}(\mu\mathbf{I}-\mathbf{B})$ is an eigenvector of $\mathbf{B}$ whenever μ is an eigenvalue, and its entries are polynomials in μ and the entries of $\mathbf{B}$. So it moves continuously when they do (this section). *Transfer:* when an object must be chosen continuously and there is no canonical choice, look for a formula that is polynomial in the data. The implicit function theorem then becomes unnecessary.

The chapter also paid promises made in earlier chapters.

The promise	Made in	Paid by
"This chapter quotes this theorem, and Chapter 19 proves it" (continuous dependence of roots on coefficients)	Chapter 15 §07	§03 (Continuity of roots)
"Chapter 19 returns to this point" (the Jordan form is not stable)	Chapter 9 §03	§03, §04 and this section
"Chapter 19 develops both and proves it" (Bauer–Fike)	Chapter 11 §11	§04 (The Bauer–Fike theorem)
"Chapter 19 proves the theorem of Bauer and Fike"	Chapter 15 §07	§04
"the theorem of Bauer and Fike, in Chapter 19"	Chapter 16 §03	§04
"the bounds that do exist, Weyl's and Bauer–Fike's, are Chapters 16 and 19"	Chapter 15 §08	§04
"Bounds for the eigenvalues of non-Hermitian matrices under perturbation, beginning with Bauer–Fike, are Chapter 19's"	Chapter 16 §11	§§03–05
"its quantitative form appears in Chapter 19" (the Sylvester equation)	Chapter 7 §04	§07 (The Sylvester equation)
"belongs with perturbation theory in Chapter 19" (conditioning of the Sylvester equation)	Chapter 11 §10	§07
"Chapter 19 leans on it for perturbation bounds" (the Hermitian dilation)	Chapter 16 §09	§10 (Singular values and polar factors)

Some things the chapter did not do. The matching form of Elsner's bound in §03 carries a factor $2n-1$, which is not the best possible, and the better constants were not pursued. The spectral-norm form of Davis–Kahan for a cluster lying between two parts of the rest of the spectrum was stated without proof (§09), and nothing depends on it. The bounds of §05, and Mirsky's theorem in §10, hold in the Frobenius norm; §10's square-root and polar bounds hold in the spectral norm as well. Extending the eigenvalue and singular value bounds to every unitarily

invariant norm belongs to Chapter 20; the square-root and polar bounds are not extended there, and stay in the two norms proved here. Finally, the residual bounds of §04 and §06 say that a computed eigenpair is an exact eigenpair of a nearby matrix. Turning that into a theory of backward error, and into algorithms that compute eigenvalues, is the subject of Chapter 23.

19.11.7 Exercises

19.11.7.1 A. Check your understanding

Exercise A1.

(a) Define the condition number $\kappa_{\mathbf{A}}(\lambda)$, saying for which λ it is defined.

(b) State the formula for the derivative of a simple eigenvalue of $\mathbf{A}+t\mathbf{E}$ at $t=0$.

(c) True or false: for every eigenvalue of every $\mathbf{A}\in M_n(\mathbb{C})$, a right eigenvector $\mathbf{x}$ and a left eigenvector $\mathbf{y}$ satisfy $\mathbf{y}^*\mathbf{x}\neq 0$. Justify your answer.

(d) True or false: if $\mathbf{A}=\mathbf{X}\mathbf{\Lambda}\mathbf{X}^{-1}$ with $\kappa_2(\mathbf{X})\geq 10^6$, then some eigenvalue of $\mathbf{A}$ has $\kappa_{\mathbf{A}}(\lambda)\geq 10^6$. Justify your answer.

(e) True or false: $\kappa_{2\mathbf{A}+3\mathbf{I}}(2\lambda+3)=\kappa_{\mathbf{A}}(\lambda)$ for every simple eigenvalue λ of $\mathbf{A}$. Justify your answer.

(f) The proof of Theorem 19.11.2 needed eigenvectors of $\mathbf{A}+t\mathbf{E}$ that converge as $t\to 0$. Where did they come from?

Solution.

(a) For a **simple** eigenvalue λ of $\mathbf{A}\in M_n(\mathbb{C})$ with right eigenvector $\mathbf{x}$ and left eigenvector $\mathbf{y}$ ($\mathbf{y}^*\mathbf{A}=\lambda\mathbf{y}^*$), $\kappa_{\mathbf{A}}(\lambda)=\|\mathbf{x}\|\|\mathbf{y}\|/|\mathbf{y}^*\mathbf{x}|$ (Definition 19.11.1).

(b) $\lambda'(0)=\mathbf{y}^*\mathbf{E}\mathbf{x}/(\mathbf{y}^*\mathbf{x})$, where $\lambda(t)$ is the unique eigenvalue of $\mathbf{A}+t\mathbf{E}$ near λ (Theorem 19.11.2).

(c) False. For $\mathbf{J}_2(0)$ the eigenvectors are the multiples of $\mathbf{x}=\mathbf{e}_1$ and of $\mathbf{y}=\mathbf{e}_2$, and $\mathbf{y}^*\mathbf{x}=0$, as in the warning after Lemma 19.11.1. The eigenvalue 0 is not simple, and simplicity is the hypothesis of that lemma.

(d) False. Let $\mathbf{A}=\operatorname{diag}(1,2)$ and $\mathbf{X}=\operatorname{diag}(1,10^6)$. Then $\mathbf{X}\mathbf{A}\mathbf{X}^{-1}=\mathbf{A}$ because diagonal matrices commute, so $\mathbf{A}=\mathbf{X}\mathbf{A}\mathbf{X}^{-1}$, and $\kappa_2(\mathbf{X})=10^6$. But $\mathbf{A}$ is normal, so both eigenvalues have condition number 1 by Proposition 19.11.3 (c). A large $\kappa_2(\mathbf{X})$ may just reflect a poor choice of $\mathbf{X}$.

(e) True. The eigenvalue $2\lambda+3$ of $2\mathbf{A}+3\mathbf{I}$ is simple, since $p_{2\mathbf{A}+3\mathbf{I}}(x)=2^n p_{\mathbf{A}}((x-3)/2)$. From $\mathbf{A}\mathbf{x}=\lambda\mathbf{x}$ and $\mathbf{y}^*\mathbf{A}=\lambda\mathbf{y}^*$ we get $(2\mathbf{A}+3\mathbf{I})\mathbf{x}=(2\lambda+3)\mathbf{x}$ and $\mathbf{y}^*(2\mathbf{A}+3\mathbf{I})=(2\lambda+3)\mathbf{y}^*$. So the same $\mathbf{x}$ and $\mathbf{y}$ serve, and the formula gives the same number.

(f) From the adjugate: a non-zero column of $\operatorname{adj}(\lambda\mathbf{I}-\mathbf{A})$ was fixed, and the same column of $\operatorname{adj}(\lambda(t)\mathbf{I}-\mathbf{A}-t\mathbf{E})$ is an eigenvector of $\mathbf{A}+t\mathbf{E}$ for $\lambda(t)$ by Theorem 6.6.2. Its entries are polynomials in $\lambda(t)$, t and the entries of $\mathbf{A}$ and $\mathbf{E}$, so it converges because $\lambda(t)$ does (Corollary 15.7.4). No implicit function theorem was used.

19.11.7.2 B. Practice

Exercise B1: Three condition numbers.

Let

$$\mathbf{A} = \begin{pmatrix} 1 & 3 & 0 \\ 0 & 5 & 4 \\ 0 & 0 & 2 \end{pmatrix}.$$

(a) For each eigenvalue of $\mathbf{A}$, find a right and a left eigenvector with integer entries, and compute $\kappa_{\mathbf{A}}(1)$, $\kappa_{\mathbf{A}}(2)$ and $\kappa_{\mathbf{A}}(5)$.

(b) Hence decide which eigenvalue is the most sensitive to first order, and find $\mathbf{E}$ with $\|\mathbf{E}\|_2 = 1$ for which that eigenvalue of $\mathbf{A} + t\mathbf{E}$ has $|\lambda'(0)|$ as large as possible.

Solution.

(a) The matrix is upper triangular with diagonal $1, 5, 2$, so these are the eigenvalues, each simple.
Eigenvalue 1. $\mathbf{x} = \mathbf{e}_1$. For $\mathbf{y}^* = (u, v, w)$, the equation $\mathbf{y}^*(\mathbf{A} - \mathbf{I}) = \mathbf{0}$ reads $(0,\ 3u + 4v,\ 4v + w) = \mathbf{0}$. Take $u = 4$, $v = -3$, $w = 12$, so $\mathbf{y} = (4, -3, 12)$, with $\|\mathbf{y}\| = \sqrt{16 + 9 + 144} = 13$ and $\mathbf{y}^*\mathbf{x} = 4$. Hence $\kappa_{\mathbf{A}}(1) = 13/4$.
Eigenvalue 2. $\mathbf{y} = \mathbf{e}_3$, since $\mathbf{e}_3^*\mathbf{A} = (0, 0, 2)$. For $\mathbf{x} = (p, q, r)$, the equation $(\mathbf{A} - 2\mathbf{I})\mathbf{x} = \mathbf{0}$ reads $-p + 3q = 0$, $3q + 4r = 0$. Take $r = 3$, $q = -4$, $p = -12$, so $\mathbf{x} = (-12, -4, 3)$, with $\|\mathbf{x}\| = \sqrt{144 + 16 + 9} = 13$ and $\mathbf{y}^*\mathbf{x} = 3$. Hence $\kappa_{\mathbf{A}}(2) = 13/3$.
Eigenvalue 5. For $\mathbf{x} = (p, q, 0)$, $(\mathbf{A} - 5\mathbf{I})\mathbf{x} = (-4p + 3q, 0, 0)$, so $\mathbf{x} = (3, 4, 0)$. For $\mathbf{y}^* = (0, v, w)$, $\mathbf{y}^*(\mathbf{A} - 5\mathbf{I}) = (0, 0, 4v - 3w)$, so $\mathbf{y} = (0, 3, 4)$. Both have length 5, and $\mathbf{y}^*\mathbf{x} = 12$. Hence $\kappa_{\mathbf{A}}(5) = 25/12$.

(b) Since $13/3 > 13/4 > 25/12$, the eigenvalue 2 is the most sensitive, although the eigenvalue 1 is exactly as close to its nearest neighbor and less sensitive: the gaps alone do not decide. By Proposition 19.11.3 (b), the worst direction is

$$\mathbf{E} = \frac{\mathbf{y}\mathbf{x}^*}{\|\mathbf{x}\|\|\mathbf{y}\|} = \frac{1}{13}\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ -12 & -4 & 3 \end{pmatrix},$$

with $\|\mathbf{E}\|_2 = 1$ and $\lambda'(0) = \|\mathbf{x}\|\|\mathbf{y}\|/(\mathbf{y}^*\mathbf{x}) = 13/3$. Hence, to first order, a perturbation of size 10^{-3} in this direction moves the eigenvalue 2 by about 4.3×10^{-3}.

Exercise B2: A derivative checked against the exact answer.

Let $\mathbf{A} = \left(\begin{smallmatrix} 0 & 1 \\ -2 & 3 \end{smallmatrix}\right)$ and $\mathbf{E} = \mathbf{E}_{12}$.

(a) Find the eigenvalues of $\mathbf{A}$ with right and left eigenvectors, and compute both condition numbers.

(b) Use Theorem 19.11.2 to find $\lambda'(0)$ for each eigenvalue of $\mathbf{A} + t\mathbf{E}$.

(c) Find the eigenvalues of $\mathbf{A} + t\mathbf{E}$ exactly. Hence compare the first-order estimate with the exact value at $t = 10^{-3}$.

Solution.

(a) $p_{\mathbf{A}}(x) = x^2 - 3x + 2 = (x - 1)(x - 2)$. For 1: $\mathbf{A} - \mathbf{I} = \left(\begin{smallmatrix} -1 & 1 \\ -2 & 2 \end{smallmatrix}\right)$, so $\mathbf{x}_1 = (1, 1)$,

and $\mathbf{y}^*(\mathbf{A}-\mathbf{I})=\mathbf{0}$ for $\mathbf{y}^*=(u,v)$ means $-u-2v=0$, so $\mathbf{y}_1=(2,-1)$. Then $\mathbf{y}_1^*\mathbf{x}_1=1$ and $\kappa_{\mathbf{A}}(1)=\sqrt{2}\sqrt{5}=\sqrt{10}$. For 2: $\mathbf{A}-2\mathbf{I}=\left(\begin{smallmatrix}-2&1\\-2&1\end{smallmatrix}\right)$, so $\mathbf{x}_2=(1,2)$ and $\mathbf{y}_2=(1,-1)$, with $\mathbf{y}_2^*\mathbf{x}_2=-1$ and $\kappa_{\mathbf{A}}(2)=\sqrt{5}\sqrt{2}=\sqrt{10}$.

(b) $\mathbf{y}^*\mathbf{E}_{12}\mathbf{x}=\overline{y_1}\,x_2$. For 1: $2\cdot 1/1=2$. For 2: $1\cdot 2/(-1)=-2$.

(c) $\mathbf{A}+t\mathbf{E}=\left(\begin{smallmatrix}0&1+t\\-2&3\end{smallmatrix}\right)$ has trace 3 and determinant $2+2t$, so its eigenvalues are $(3\mp\sqrt{1-8t})/2$, for $t<1/8$. Differentiating at $t=0$ gives ± 2, as in (b). At $t=10^{-3}$, the first-order estimates are 1.002 and 1.998, and the exact values are $(3\mp\sqrt{0.992})/2\approx 1.002004$ and 1.997996. Hence the error of the first-order estimate is about 4×10^{-6}, which is of the order of t^2, as expected of a first-order approximation.

Exercise B3: Invariance of the condition number.

Let λ be a simple eigenvalue of $\mathbf{A}\in M_n(\mathbb{C})$. Prove that:

(a) $\overline{\lambda}$ is a simple eigenvalue of $\mathbf{A}^*$, and $\kappa_{\mathbf{A}^*}(\overline{\lambda})=\kappa_{\mathbf{A}}(\lambda)$;

(b) $\kappa_{\mathbf{U}^*\mathbf{A}\mathbf{U}}(\lambda)=\kappa_{\mathbf{A}}(\lambda)$ for every unitary $\mathbf{U}$.

(c) Explain why (b) fails for a general invertible $\mathbf{S}$ in place of $\mathbf{U}$, using $\mathbf{A}=\operatorname{diag}(1,2)$.

Solution.

(a) The characteristic polynomial of $\mathbf{A}^*$ has as roots the conjugates of those of $\mathbf{A}$, with the same multiplicities: $p_{\mathbf{A}^*}(x)=\det(x\mathbf{I}-\mathbf{A}^*)=\overline{\det(\overline{x}\mathbf{I}-\mathbf{A})}$, because the determinant of the conjugate transpose is the conjugate of the determinant. So $\overline{\lambda}$ is a simple eigenvalue of $\mathbf{A}^*$. If $\mathbf{A}\mathbf{x}=\lambda\mathbf{x}$ and $\mathbf{y}^*\mathbf{A}=\lambda\mathbf{y}^*$, then taking conjugate transposes gives $\mathbf{x}^*\mathbf{A}^*=\overline{\lambda}\mathbf{x}^*$ and $\mathbf{A}^*\mathbf{y}=\overline{\lambda}\mathbf{y}$. So for $\mathbf{A}^*$ and $\overline{\lambda}$, the vector $\mathbf{y}$ is a right eigenvector and $\mathbf{x}$ a left one. Hence $\kappa_{\mathbf{A}^*}(\overline{\lambda})=\|\mathbf{y}\|\|\mathbf{x}\|/|\mathbf{x}^*\mathbf{y}|=\kappa_{\mathbf{A}}(\lambda)$, since $|\mathbf{x}^*\mathbf{y}|=|\overline{\mathbf{y}^*\mathbf{x}}|=|\mathbf{y}^*\mathbf{x}|$.

(b) $\mathbf{U}^*\mathbf{A}\mathbf{U}$ has the same characteristic polynomial as $\mathbf{A}$ (Theorem 6.10.3), so λ is simple for it. From $\mathbf{A}\mathbf{x}=\lambda\mathbf{x}$ and $\mathbf{y}^*\mathbf{A}=\lambda\mathbf{y}^*$ we get $(\mathbf{U}^*\mathbf{A}\mathbf{U})(\mathbf{U}^*\mathbf{x})=\lambda\,\mathbf{U}^*\mathbf{x}$ and $(\mathbf{U}^*\mathbf{y})^*(\mathbf{U}^*\mathbf{A}\mathbf{U})=\mathbf{y}^*\mathbf{A}\mathbf{U}=\lambda\,(\mathbf{U}^*\mathbf{y})^*$. Since $\mathbf{U}^*$ is unitary, $\|\mathbf{U}^*\mathbf{x}\|=\|\mathbf{x}\|$ and $\|\mathbf{U}^*\mathbf{y}\|=\|\mathbf{y}\|$ (Theorem 10.7.3), and $(\mathbf{U}^*\mathbf{y})^*(\mathbf{U}^*\mathbf{x})=\mathbf{y}^*\mathbf{U}\mathbf{U}^*\mathbf{x}=\mathbf{y}^*\mathbf{x}$. So all three ingredients of Definition 19.11.1 are unchanged.

(c) For $\mathbf{S}=\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$, $\mathbf{S}^{-1}\mathbf{A}\mathbf{S}=\left(\begin{smallmatrix}1&-1\\0&1\end{smallmatrix}\right)\left(\begin{smallmatrix}1&1\\0&2\end{smallmatrix}\right)=\left(\begin{smallmatrix}1&-1\\0&2\end{smallmatrix}\right)$. By Example (The condition numbers of a triangular 2×2 matrix) (a) with $b=-1$ and $|a-d|=1$, its eigenvalue 1 has condition number $\sqrt{2}$, whereas $\kappa_{\mathbf{A}}(1)=1$ because $\mathbf{A}$ is normal. A non-unitary similarity changes lengths and angles, so it changes the angle between $\mathbf{x}$ and $\mathbf{y}$ in Proposition 19.11.3 (e).

19.11.7.3 C. Going deeper

Exercise C1: Perfect conditioning characterizes normality.

(a) Let $\mathbf{A}\in M_n(\mathbb{C})$ have n distinct eigenvalues. Prove that $\mathbf{A}$ is normal if and only if $\kappa_{\mathbf{A}}(\lambda)=1$ for every eigenvalue λ.

(b) Show that the hypothesis of distinct eigenvalues cannot be replaced by "$\kappa_{\mathbf{A}}(\lambda)=1$ for every **simple** eigenvalue λ": give a non-normal $\mathbf{A}\in M_3(\mathbb{C})$ with a simple eigenvalue, all of whose simple eigenvalues have condition number 1.

Hint: in (a), what does $\kappa = 1$ say about $\mathbf{y}$, and what does the computation in Theorem 8.10.6 say about $\mathbf{y}_j^* \mathbf{x}_i$?

Solution.

(a) ($\Rightarrow$) This is Proposition 19.11.3 (c).
($\Leftarrow$) Let $\lambda_1, \dots, \lambda_n$ be the distinct eigenvalues, with right eigenvectors $\mathbf{x}_1, \dots, \mathbf{x}_n$. Since $\kappa_{\mathbf{A}}(\lambda_j) = 1$, Proposition 19.11.3 (a) says that a left eigenvector for λ_j is a multiple of $\mathbf{x}_j$, so $\mathbf{x}_j$ itself is one: $\mathbf{x}_j^* \mathbf{A} = \lambda_j \mathbf{x}_j^*$. Let $i \neq j$. Computing $\mathbf{x}_j^* \mathbf{A} \mathbf{x}_i$ in two ways,

$$\lambda_j \, \mathbf{x}_j^* \mathbf{x}_i = (\mathbf{x}_j^* \mathbf{A}) \mathbf{x}_i = \mathbf{x}_j^* (\mathbf{A} \mathbf{x}_i) = \lambda_i \, \mathbf{x}_j^* \mathbf{x}_i,$$

so $(\lambda_j - \lambda_i) \mathbf{x}_j^* \mathbf{x}_i = 0$, and $\mathbf{x}_j^* \mathbf{x}_i = 0$ because $\lambda_i \neq \lambda_j$. So the vectors $\mathbf{x}_i / \|\mathbf{x}_i\|$ form an orthonormal list of n vectors in $\mathbb{C}^n$, hence an orthonormal basis of eigenvectors. With $\mathbf{U}$ the unitary matrix having these columns, $\mathbf{A} = \mathbf{U} \operatorname{diag}(\lambda_1, \dots, \lambda_n) \mathbf{U}^*$, so $\mathbf{A}$ is normal by Corollary 11.4.3.

(b) Let $\mathbf{A} = \mathbf{J}_2(0) \oplus (1) = \left(\begin{smallmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{smallmatrix}\right)$. Its eigenvalues are $0, 0, 1$, so 1 is the only simple eigenvalue. Its right and left eigenvectors are both $\mathbf{e}_3$, since $\mathbf{A}\mathbf{e}_3 = \mathbf{e}_3$ and $\mathbf{e}_3^* \mathbf{A} = \mathbf{e}_3^*$, so $\kappa_{\mathbf{A}}(1) = 1$. But $\mathbf{A}$ is not normal: $\mathbf{A}^* \mathbf{A} = \operatorname{diag}(0, 1, 1)$ while $\mathbf{A}\mathbf{A}^* = \operatorname{diag}(1, 0, 1)$.

Exercise C2: The derivatives add up to the trace.

Let $\mathbf{A} \in M_n(\mathbb{C})$ have n distinct eigenvalues $\lambda_1, \dots, \lambda_n$, and let $\mathbf{E} \in M_n(\mathbb{C})$. Write $\lambda_i(t)$ for the eigenvalue of $\mathbf{A} + t\mathbf{E}$ near λ_i, from Theorem 19.11.2.

(a) Prove that $\lambda_1'(0) + \cdots + \lambda_n'(0) = \operatorname{tr} \mathbf{E}$.

(b) Deduce this again from $\operatorname{tr}(\mathbf{A} + t\mathbf{E}) = \lambda_1(t) + \cdots + \lambda_n(t)$, valid for all small t, and explain why the two arguments agree.

Hint: in (a), use a diagonalizing $\mathbf{X}$ and the rows of $\mathbf{X}^{-1}$ as left eigenvectors.

Solution.

(a) $\mathbf{A}$ is diagonalizable by Corollary 8.4.2, say $\mathbf{A} = \mathbf{X} \mathbf{\Lambda} \mathbf{X}^{-1}$. As in the proof of Proposition 19.11.3 (d), $\mathbf{x}_i = \mathbf{X}\mathbf{e}_i$ and $\mathbf{y}_i^* = \mathbf{e}_i^* \mathbf{X}^{-1}$ are right and left eigenvectors for λ_i, with $\mathbf{y}_i^* \mathbf{x}_i = 1$. So by Theorem 19.11.2,

$$\sum_{i=1}^{n} \lambda_i'(0) = \sum_{i=1}^{n} \mathbf{e}_i^* \mathbf{X}^{-1} \mathbf{E} \mathbf{X} \mathbf{e}_i = \operatorname{tr}(\mathbf{X}^{-1} \mathbf{E} \mathbf{X}) = \operatorname{tr} \mathbf{E},$$

where the middle equality sums the diagonal entries of $\mathbf{X}^{-1}\mathbf{E}\mathbf{X}$ and the last uses $\operatorname{tr}(\mathbf{B}\mathbf{C}) = \operatorname{tr}(\mathbf{C}\mathbf{B})$ (Theorem 0.9.6 (3)).

(b) Let g be the smallest distance between two of the λ_i. By Theorem 19.11.2 (b), $|\lambda_i(t) - \lambda_i| < g/2$ for every i once $|t|$ is small enough, so $\lambda_1(t), \dots, \lambda_n(t)$ are n distinct eigenvalues of $\mathbf{A} + t\mathbf{E}$. They are therefore all of its eigenvalues, each simple, and Theorem 8.3.3 gives $\operatorname{tr}(\mathbf{A} + t\mathbf{E}) = \sum_i \lambda_i(t)$. The left side is $\operatorname{tr} \mathbf{A} + t \operatorname{tr} \mathbf{E}$ and $\operatorname{tr} \mathbf{A} = \sum_i \lambda_i$, so $\sum_i (\lambda_i(t) - \lambda_i)/t = \operatorname{tr} \mathbf{E}$ for small $t \neq 0$. Letting $t \to 0$ and using (c) of the theorem for each i gives the claim. The two arguments agree because both express the same fact: the sum of the eigenvalues is a linear function

of the matrix, so its derivative in the direction $\mathbf{E}$ is $\operatorname{tr}\mathbf{E}$, whatever the individual derivatives are.

Exercise C3: The adjugate at a simple eigenvalue.

Let $n \geq 2$, let λ be a simple eigenvalue of $\mathbf{A} \in M_n(\mathbb{C})$ with right eigenvector $\mathbf{x}$ and left eigenvector $\mathbf{y}$, and put $\mathbf{N} = \lambda\mathbf{I} - \mathbf{A}$.

(a) Prove that $\operatorname{adj}\mathbf{N} = c\,\mathbf{x}\mathbf{y}^*$ for some scalar $c \neq 0$.

(b) Prove that $\operatorname{tr}(\operatorname{adj}\mathbf{N}) = p'_{\mathbf{A}}(\lambda)$, the derivative of the characteristic polynomial at λ.

(c) Deduce a second proof that $\mathbf{y}^*\mathbf{x} \neq 0$, and the formula

$$\operatorname{adj}(\lambda\mathbf{I} - \mathbf{A}) = p'_{\mathbf{A}}(\lambda)\,\frac{\mathbf{x}\mathbf{y}^*}{\mathbf{y}^*\mathbf{x}}.$$

Hint: for (a), use both products in Theorem 6.6.2; for (b), apply Theorem 15.6.6 to $t \mapsto (\lambda + t)\mathbf{I} - \mathbf{A}$.

Solution.

(a) Since λ is an eigenvalue, $\det\mathbf{N} = 0$, so Theorem 6.6.2 gives $\mathbf{N}\operatorname{adj}\mathbf{N} = \mathbf{0}$ and $\operatorname{adj}\mathbf{N}\,\mathbf{N} = \mathbf{0}$. The first says every column of $\operatorname{adj}\mathbf{N}$ lies in $\ker(\lambda\mathbf{I} - \mathbf{A})$, so by Lemma 19.11.1 (a) every column is a multiple of $\mathbf{x}$: $\operatorname{adj}\mathbf{N} = \mathbf{x}\mathbf{w}^*$ for some $\mathbf{w} \in \mathbb{C}^n$, whose conjugated entries are those multiples. Step 3 of the proof of Theorem 19.11.2 showed that $\operatorname{adj}\mathbf{N} \neq \mathbf{0}$, so $\mathbf{w} \neq \mathbf{0}$. The second identity gives $\mathbf{x}(\mathbf{w}^*\mathbf{N}) = \mathbf{0}$, and since $\mathbf{x} \neq \mathbf{0}$ this forces $\mathbf{w}^*\mathbf{N} = \mathbf{0}$, that is, $\mathbf{w}^*\mathbf{A} = \lambda\mathbf{w}^*$. So $\mathbf{w}$ is a left eigenvector, hence $\mathbf{w} = \bar{c}\,\mathbf{y}$ for some $c \neq 0$ by Lemma 19.11.1 (a), and $\operatorname{adj}\mathbf{N} = c\,\mathbf{x}\mathbf{y}^*$.

(b) Let $\mathbf{B}(t) = (\lambda + t)\mathbf{I} - \mathbf{A}$ for real t, so $\mathbf{B}'(0) = \mathbf{I}$ and $\mathbf{B}(0) = \mathbf{N}$. By Theorem 15.6.6, $t \mapsto \det\mathbf{B}(t)$ is differentiable at 0 with derivative $\operatorname{tr}(\operatorname{adj}\mathbf{N}\,\mathbf{I}) = \operatorname{tr}(\operatorname{adj}\mathbf{N})$. On the other hand $\det\mathbf{B}(t) = p_{\mathbf{A}}(\lambda + t)$. Expanding each power $(\lambda + t)^k$ by the binomial theorem gives $p_{\mathbf{A}}(\lambda + t) = p_{\mathbf{A}}(\lambda) + p'_{\mathbf{A}}(\lambda)\,t + t^2 h(t)$ for a polynomial h, because the coefficient of t in $\sum_k c_k(\lambda + t)^k$ is $\sum_k k c_k \lambda^{k-1} = p'_{\mathbf{A}}(\lambda)$. So the difference quotient at 0 is $p'_{\mathbf{A}}(\lambda) + t\,h(t) \to p'_{\mathbf{A}}(\lambda)$. The two derivatives agree: $\operatorname{tr}(\operatorname{adj}\mathbf{N}) = p'_{\mathbf{A}}(\lambda)$.

(c) By (a) and (b), $p'_{\mathbf{A}}(\lambda) = \operatorname{tr}(c\,\mathbf{x}\mathbf{y}^*) = c\,\mathbf{y}^*\mathbf{x}$, since the trace of $\mathbf{x}\mathbf{y}^*$ is $\sum_i x_i\overline{y_i} = \mathbf{y}^*\mathbf{x}$. Because λ is a simple root of $p_{\mathbf{A}}$, Theorem 5.4.5 (a) gives $p'_{\mathbf{A}}(\lambda) \neq 0$. Hence $\mathbf{y}^*\mathbf{x} \neq 0$, which reproves Lemma 19.11.1 (b) from (a) of that lemma. Moreover $c = p'_{\mathbf{A}}(\lambda)/(\mathbf{y}^*\mathbf{x})$, which is the displayed formula. For example, for $\mathbf{A} = \left(\begin{smallmatrix} 1 & M \\ 0 & 2 \end{smallmatrix}\right)$ and $\lambda = 1$, we have $\operatorname{adj}(\mathbf{I} - \mathbf{A}) = \left(\begin{smallmatrix} -1 & M \\ 0 & 0 \end{smallmatrix}\right)$ and $p'_{\mathbf{A}}(1) = -1$, while $\mathbf{x}\mathbf{y}^*/(\mathbf{y}^*\mathbf{x}) = \left(\begin{smallmatrix} 1 & -M \\ 0 & 0 \end{smallmatrix}\right)$, in agreement.

Chapter 20

Matrix Inequalities

Five chapters have left inequalities unpaid, and they turn out to be one inequality seen from five sides. Chapter 12 §09 and §10 said that the truncated singular value decomposition and the unitary polar factor are nearest in "every unitarily invariant norm", a phrase it could not define. Chapter 15 §08 admitted that it had never said which norms those are. Chapter 16 §06 found a family of functionals that fail to be norms on Hermitian matrices and guessed the repair; §07 proved a majorization and left its consequences open; §11 stated Loewner's theorem once, promised this chapter's proof four times, and proved none of it. Chapter 17 §10 and §11 deferred the convexity of $\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A})$. Chapter 18 §07 and §09 deferred the theorem of Hardy, Littlewood and Pólya. Chapter 19 §05, §10 and §11 wanted Weyl's, Mirsky's and Hoffman–Wielandt's bounds inside one statement.

The organizing fact behind all of them is **majorization**, the order $\mathbf{x} \prec \mathbf{y}$ that Chapter 16 §08 defined. This chapter closes the circle in four movements.

- **Majorization is a doubly stochastic map.** $\mathbf{x} \prec \mathbf{y}$ exactly when $\mathbf{x} = \mathbf{D}\mathbf{y}$ for a doubly stochastic $\mathbf{D}$, and with Birkhoff's theorem, exactly when $\mathbf{x}$ lies in the convex hull of the permutations of $\mathbf{y}$. Convexity then acts one row at a time, and every convex function respects the order.
- **A majorization becomes a norm inequality.** The norms that cannot tell coordinates apart are the symmetric gauge functions; composing one with the singular values gives a unitarily invariant norm, and every unitarily invariant norm arises this way exactly once. Ky Fan dominance then says that "$|||\mathbf{A}||| \le |||\mathbf{B}|||$ for every unitarily invariant norm" and "$\sigma(\mathbf{A}) \prec_w \sigma(\mathbf{B})$" are the same statement.
- **The deferred theorems fall out.** Eckart–Young, the nearest unitary matrix, Lidskii and Mirsky, each in every unitarily invariant norm at once.
- **The order-theoretic side.** Which functions preserve the Loewner order $\mathbf{A} \succeq \mathbf{B}$? Very few: Loewner's theorem says they are exactly the functions with a particular integral representation, and the powers t^p qualify only for $0 \le p \le 1$. The chapter ends with the exponential, where Golden and Thompson's trace inequality replaces the identity $e^{a+b} = e^a e^b$ that matrices cannot have.

Matrices are complex unless a statement says otherwise, and f applied to a Hermitian matrix always means the spectral functional calculus of Chapter 11 §08 (Definition 11.8.2). Four notational conventions hold throughout.

- $\boldsymbol{\lambda}(\mathbf{A})$ **is the decreasing eigenvalue list** of a Hermitian $\mathbf{A}$, $\sigma(\mathbf{A})$ the decreasing singular value list, and $\mathbf{x}^{\downarrow}$ the decreasing rearrangement of a real vector, as in Chapter 16.

- **Majorization is Chapter 16 §08's** (Definition 16.8.1), with $\prec_w$ the top-sums version.
- **A unitarily invariant norm is written $|||\mathbf{A}|||$**, with triple bars, to keep it apart from any particular norm. **Symmetric gauge functions are Φ**; Chapter 17 §04's gauge p_K of a convex set is a different object with the same word, and §03 says so once.
- **The order on matrices is always the Loewner order $\mathbf{A} \succeq \mathbf{B}$** of Chapter 12 §05 (Definition 12.5.1). No matrix is ever compared entrywise: the order of Chapters 17 and 18 is used here only on **vectors**, as $\mathbf{x} \leq \mathbf{y}$ in §03, which says so at its head.

20.0.1 The analysis this chapter imports

The list is Chapter 15's, facts **(A1)**–**(A6)** of that chapter's introduction — completeness, monotone convergence, compactness of closed bounded sets, the extreme value theorem, the intermediate value theorem and the mean value theorem — together with the **algebra of limits**. Each is named again where it is used, except the intermediate value theorem **(A5)**, which this chapter never needs. The weight falls on three: **(A1)** and **(A3)** build §10's integral, completeness for the convergence of the Riemann sums and compactness for the uniform continuity of the integrand, and **(A6)** is how §09 turns a non-negative derivative into monotonicity along a segment. Section 9 also uses **(A3)** and **(A4)** for the same two jobs, uniform continuity and boundedness on a compact interval, and **(A2)** bounds the improper integral of §10 that represents t^p.

One fact is quoted beyond that list, and it is this chapter's own. Loewner's theorem cannot be proved from (A1)–(A6): its analytic half is a theorem about functions of a complex variable. The book's practice, as with Taylor's theorem in Chapter 13 §06 and the theorem of Abel and Ruffini in Chapter 10, is to quote one named result at its point of use and prove everything else. So:

(A7) (Pick and Nevanlinna.) *Let $I \subseteq \mathbb{R}$ be an open interval and $f\colon I \to \mathbb{R}$. Suppose the Loewner matrix $\big[f[t_i, t_j]\big]_{i,j=1}^{n}$ of divided differences is positive semidefinite for every n and all $t_1, \ldots, t_n \in I$. Then f is the restriction to I of a function that is analytic on $\mathbb{C} \setminus (\mathbb{R} \setminus I)$ and maps the upper half plane into its closure; and every such function has the integral representation of Chapter 16 §11's Theorem 16.11.9 (ii). In particular such an f is automatically infinitely differentiable on I.*

(A7) is stated once, in §10, and used three times there. Its clause (c) supplies the smoothness that §09's criterion asks for, its clause (a) the implication (i) $\Rightarrow$ (iii) of Loewner's theorem, and its clause (b) the implication (iii) $\Rightarrow$ (ii). Together they give the one thing the chapter cannot prove: that a function which is operator monotone of every order has the integral representation. No other section uses it, and everything else in the chapter is proved.

What this means in practice is worth spelling out, because the reader should know which results are conditional.

- **Resting on (A7):** only the implication just named, and therefore only the "hard" direction of Theorem 16.11.9 — that (i) implies (ii). Section 10 marks each step where it enters.
- **Not resting on (A7):** everything in §§01–08, §11 and §12; the whole of §09, including the criterion that, for a continuously differentiable f, monotonicity of order n is exactly positivity of every $n \times n$ Loewner matrix, which is the elementary heart of Loewner's theorem and is proved in full; the **easy** direction of Loewner's theorem, that the integral representation forces operator monotonicity, which §10 proves outright; the operator monotonicity of t^p for $0 \leq p \leq 1$ and of $\log t$, both obtained from that easy direction together with an explicit representation; and the three negative results — that t^p fails for every $p > 1$, that

t^2 fails already at order 2, and that e^t is not operator monotone — which come from §09's criterion and from explicit two-by-two witnesses.

Section 10 also integrates a continuous matrix-valued function over a compact interval. That is **not** imported: the section builds the integral entrywise as a limit of Riemann sums, using only (A1)–(A4), and proves the one property it needs, that an integral of positive semidefinite matrices is positive semidefinite. Beyond the list, the only analytic fact quoted is the fundamental theorem of calculus, which §10 uses twice and flags both times: in a remark, to check the logarithm's integral representation, and in an exercise, to evaluate the constant $K_{1/2}$. Neither use is a step in a proof. In particular §09's derivative of a matrix function is obtained without the implicit function theorem, exactly as Chapter 19 §11's derivative of a simple eigenvalue was.

20.0.2 What you need

- **Chapter 0 §09** — matrix multiplication, and the trace with its cyclic invariance: Definition 0.9.9, Theorem 0.9.6.
- **Chapter 2** — the invertibility criteria and permutation matrices: Theorem 2.4.4, Definition 2.6.2, Lemma 2.6.6.
- **Chapter 5 §06** — Lagrange interpolation: Theorem 5.6.1.
- **Chapter 6 §05** — multiplicativity of the determinant: Theorem 6.5.4.
- **Chapter 7 §01** — block multiplication: Theorem 7.1.1.
- **Chapter 8** — the trace and determinant read off the eigenvalues, and the spectra of **AB** and **BA**: Theorem 8.3.3, Theorem 8.10.4.
- **Chapter 9 §09** — the matrix exponential: Definition 9.9.2, Theorem 9.9.4.
- **Chapter 10 §01** — the Frobenius inner product, Pythagoras and Cauchy–Schwarz: Theorem 10.1.3, Theorem 10.1.5.
- **Chapter 11** — the spectral theorem, the spectral resolution, the functional calculus and the unitary invariance of the Frobenius norm: Corollary 11.1.4, Theorem 11.2.1, Corollary 11.4.3, Corollary 11.5.2, Definition 11.8.1, Theorem 11.8.1, Theorem 11.8.2, Definition 11.8.2, Theorem 11.8.3, Theorem 11.8.5, Lemma 11.11.1.
- **Chapter 12** — positive semidefiniteness, square roots, the Loewner order, the Schur product theorem and the singular value and polar decompositions: Definition 12.1.1, Proposition 12.1.2, Theorem 12.1.4, Theorem 12.1.5, Theorem 12.2.1, Definition 12.5.1, Proposition 12.5.1, Lemma 12.5.2, Theorem 12.5.3, Example (Squaring does not preserve the Loewner order), Proposition 12.5.4, Theorem 12.6.1, Definition 12.7.1, Theorem 12.7.2, Definition 12.8.1, Theorem 12.8.1, Theorem 12.8.2, Theorem 12.9.1, Corollary 12.9.2, Definition 12.10.1, Theorem 12.10.3.
- **Chapter 14 §04** — the pairing Chapter 14 calls a **contraction**, a word §08 gives a different meaning: Definition 14.4.1.
- **Chapter 15** — norms, the operator norm, entrywise convergence, bounds for the exponential and the derivative of a matrix-valued function: Definition 15.1.1, Example (The 1-, 2- and ∞-norms on F^n), Corollary 15.2.4, Definition 15.3.2, Theorem 15.3.2, Theorem 15.3.3, Theorem 15.6.1, Definition 15.6.1.
- **Chapter 16** — the variational descriptions, Weyl's and Lidskii's inequalities, majorization, the Hermitian dilation and the operator monotone functions: Corollary 16.2.4, Lemma 16.3.5, Corollary 16.3.6, Theorem 16.6.2, Corollary 16.6.5, Exercise (C2: Partial sums that behave like a norm), Theorem 16.7.2, Definition 16.8.1, Example (A chain, the two extremes, and size one), Proposition 16.8.1, Lemma 16.8.3, Lemma 16.8.6, Lemma 16.9.1, Theorem 16.9.2, Proposition 16.9.3, Theorem 16.9.4, Corollary 16.9.5, Theorem 16.9.6, Definition 16.11.1, Proposition 16.11.1, Proposition 16.11.2, Proposition 16.11.3, Proposi-

tion 16.11.4, Corollary 16.11.5, Proposition 16.11.8, Theorem 16.11.9.

- **Chapter 17** — convex sets and hulls, convex functions, Jensen's inequality, gauges and duality, and the classical inequalities: Example (The vectors majorized by a fixed vector), Proposition 17.1.1, Lemma 17.1.2, Definition 17.1.4, Theorem 17.1.3, Definition 17.4.1, Definition 17.4.4, Proposition 17.4.6, Proposition 17.4.7, Theorem 17.4.8, Definition 17.8.3, Definition 17.8.4, Definition 17.10.1, Example (First convex functions), Theorem 17.10.2, Proposition 17.10.3, Lemma 17.10.5, Theorem 17.10.6, Lemma 17.11.1, Corollary 17.11.5, Theorem 17.11.6.
- **Chapter 18 §07** — Birkhoff's theorem and the half of Hardy–Littlewood–Pólya already proved: Theorem 18.7.2, Proposition 18.7.6.
- **Chapter 19** — the derivative of a simple eigenvalue, the norm toolkit behind Davis–Kahan, and the perturbation bounds this chapter upgrades: Corollary 19.5.4, Lemma 19.9.1, Theorem 19.10.1, Theorem 19.11.2.

20.0.3 Roadmap

- **Doubly stochastic maps.** T-transforms average two coordinates, and finitely many of them turn $\mathbf{y}$ into any $\mathbf{x} \prec \mathbf{y}$. That is the theorem of Hardy, Littlewood and Pólya, and with Birkhoff's theorem it says that the majorization order is containment of permutation polytopes.
- **Convex functions of a majorization.** Karamata's inequality, its converse, Schur-convex and Schur-concave functions, and the convexity of $\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A})$ for every convex f.
- **Symmetric gauge functions.** Norms on $\mathbb{R}^n$ blind to the order and the signs of the coordinates. They are monotone under weak majorization, and they have a duality theory of their own.
- **Unitarily invariant norms.** The norms unchanged by unitary factors on either side: the Frobenius and spectral norms, the Ky Fan k-norms and the Schatten p-norms. Von Neumann's correspondence matches them exactly with the symmetric gauges, through $|||\mathbf{A}||| = \Phi(\sigma(\mathbf{A}))$.
- **The trace inequality.** $|\operatorname{tr}(\mathbf{A}^*\mathbf{B})| \le \sum_i \sigma_i(\mathbf{A})\sigma_i(\mathbf{B})$, and the duality it gives between a unitarily invariant norm and the norm of the dual gauge.
- **Ky Fan dominance.** Weak majorization of singular values is equivalent to domination in every unitarily invariant norm. Eckart–Young and the nearest unitary matrix follow, in every such norm.
- **Lidskii in majorization form.** Chapter 16's majorization, run through the previous three sections, yields one bound for every convex function and one for every unitarily invariant norm, with Hoffman–Wielandt and Mirsky as special cases.
- **Operator convex functions.** The Hansen–Pedersen–Jensen inequality $f(\mathbf{V}^*\mathbf{A}\mathbf{V}) \preceq \mathbf{V}^* f(\mathbf{A})\mathbf{V}$ for a contraction $\mathbf{V}$, proved by dilating $\mathbf{V}$ to a unitary matrix, and the contrast with the far weaker trace convexity of §02.
- **Loewner matrices.** The derivative of f at a diagonal matrix is a Hadamard product with the matrix of divided differences. With the Schur product theorem this makes monotonicity of order n equivalent to positivity of every $n \times n$ Loewner matrix.
- **Loewner's theorem.** The three conditions of Chapter 16 §11 are equivalent. One implication quotes (A7); the rest is proved, including the integral machinery. The powers t^p are operator monotone exactly for $0 \le p \le 1$, $\log t$ is, and e^t is not.
- **Means and matrix Cauchy–Schwarz.** Cauchy–Schwarz and the arithmetic–geometric mean inequality for matrices, each holding in every unitarily invariant norm at once; then the matrix geometric mean $\mathbf{A}\#\mathbf{B}$, its surprising symmetry, and the chain from the

harmonic through the geometric to the arithmetic mean in the Loewner order.
- **Golden–Thompson.** Lie's product formula, a trace inequality for powers of a product of two positive matrices, and $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}} \le \operatorname{tr}(e^{\mathbf{A}} e^{\mathbf{B}})$. Three matrices break it. Then Klein's inequality and the relative entropy, Lieb's concavity theorem stated and not proved, and a summary that closes the chapter and Part V.

20.0.4 Named moves

- **A majorization is a doubly stochastic map.** Turn the family of partial-sum inequalities into a single linear map, and let convexity act one row at a time.
- **A symmetric gauge turns a weak majorization into a norm inequality.** To prove one inequality for a whole family of norms, find the combinatorial statement about the underlying numbers that every member of the family respects.
- **A Hermitian dilation turns singular values into eigenvalues.** Every theorem about the eigenvalues of a Hermitian matrix has a singular-value twin, obtained by applying it to $\mathcal{H}(\mathbf{A})$.
- **The Schur product theorem turns a Loewner matrix into monotonicity.** Differentiate a matrix function, recognize the derivative as an entrywise product with a positive semidefinite matrix, and integrate along a segment.
- **A limit of Riemann sums carries the Loewner order through an integral.** An order defined by a closed convex cone survives every limit, so it survives integration.
- **Lie's product formula turns a sum in the exponent into a product.** Split one operation into k small steps, make the error of a single step $O(1/k^2)$, and let telescoping absorb the factor k.

20.1 Doubly Stochastic Maps

Chapter 16 §08 defined majorization and Chapter 18 §07 proved one half of the fact that makes it useful: a doubly stochastic matrix can only even a vector out, $\mathbf{Sy} \prec \mathbf{y}$. The other half was promised twice. Chapter 18 §07 ended by saying that "this converse of the proposition is part of the theorem of Hardy, Littlewood and Pólya, which Chapter 20 takes up", and Chapter 18 §09 listed among its unfinished business "the theorem of Hardy, Littlewood and Pólya, that $\mathbf{x} \prec \mathbf{y}$ exactly when $\mathbf{x} = \mathbf{Dy}$ for a doubly stochastic $\mathbf{D}$". This section pays both. The proof builds $\mathbf{D}$ out of one very simple move, repeated: average two coordinates and leave the rest alone.

Throughout, vectors are real, $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$, and $\prec$ and $\prec_w$ are Chapter 16 §08's Definition 16.8.1. Recall $\mathbf{x}^{\downarrow}$, the decreasing rearrangement, and Ω_n, the set of doubly stochastic matrices of Definition 17.8.4: non-negative entries, every row and every column adding up to 1. Recall also Proposition 18.7.6, the half already proved: if $\mathbf{S} \in \Omega_n$ and $\mathbf{y} \in \mathbb{R}^n$, then $\mathbf{Sy} \prec \mathbf{y}$.

20.1.1 What is still missing

Chapter 18 got the easy direction from Birkhoff's theorem in three lines. A doubly stochastic $\mathbf{S}$ is an average of permutation matrices, a permutation only rearranges $\mathbf{y}$, and majorization cannot see a rearrangement; so $\mathbf{Sy}$ is an average of vectors all majorized by $\mathbf{y}$, and the set of such vectors is convex.

Read backwards, that argument gives nothing. It starts from a matrix and produces a majorization. We now want to start from the majorization $\mathbf{x} \prec \mathbf{y}$, which is a list of $n-1$ inequalities about sorted partial sums together with one equality of totals, and manufacture a matrix. Nothing in Definition 16.8.1 mentions a matrix, so one has to be built.

One such matrix is in fact already available. Chapter 18 §07 observed that Theorem 16.8.5 realizes any $\mathbf{x} \prec \mathbf{y}$ as the diagonal of a Hermitian $\mathbf{A}$ with $\boldsymbol{\lambda}(\mathbf{A}) = \mathbf{y}^{\downarrow}$, while Lemma 18.7.5 writes that diagonal as $\mathbf{S}\mathbf{y}^{\downarrow}$ for a doubly stochastic $\mathbf{S}$; composing with the permutation matrix that sorts $\mathbf{y}$ gives $\mathbf{x} = \mathbf{D}\mathbf{y}$ with $\mathbf{D} \in \Omega_n$. What that route does not give is any grip on $\mathbf{D}$, which arrives as the squared moduli of the entries of a unitary matrix supplied by an existence theorem. The construction below builds $\mathbf{D}$ by hand instead, as a product of at most $n-1$ factors, each of which averages a single pair of coordinates and fixes the rest.

Here is the smallest case, done by hand, to see what a construction might look like. Let $n = 2$ and $\mathbf{x} \prec \mathbf{y}$ with both decreasing, so $x_1 + x_2 = y_1 + y_2$ and $x_1 \le y_1$. Also $x_2 \ge y_2$, since subtracting $x_1 \le y_1$ from the equal totals reverses the inequality. So $y_2 \le x_1 \le y_1$, and x_1 is a weighted average of y_1 and y_2: if $y_1 = y_2$ then $\mathbf{x} = \mathbf{y}$, and otherwise

$$x_1 = (1-t)y_1 + t y_2, \qquad t = \frac{y_1 - x_1}{y_1 - y_2} \in [0,1].$$

The equal totals then force $x_2 = t y_1 + (1-t)y_2$. In matrix form,

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} 1-t & t \\ t & 1-t \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix},$$

and the matrix is doubly stochastic. So for $n = 2$ and sorted vectors the converse holds, with a $\mathbf{D}$ of a very special shape.

This is the same computation as Lemma 16.8.3, where the weights were c^2 and s^2 for a rotation and the averaged numbers were two eigenvalues. There the averaging was performed by conjugating a diagonal matrix; here it is performed on the vector directly. Both say: *any number between two others is an average of them*, and that single fact is the engine of this section.

20.1.2 Averaging two coordinates

The 2×2 matrix above can be planted inside $\mathbf{I}_n$, at any pair of positions. That gives the move we will repeat.

A T-transform mixes two coordinates and leaves every other coordinate alone.

Definition 20.1.1 — T-transform

Let $n \ge 2$, let $1 \le j < k \le n$, and let $\mathbf{Q} \in M_n(\mathbb{R})$ be the permutation matrix (Definition 2.6.2) of the transposition interchanging j and k. For a real number t with $0 \le t \le 1$, the matrix

$$\mathbf{T} = (1-t)\mathbf{I} + t\mathbf{Q}$$

is called a **T-transform**, and we say that it **acts on the pair** $\{j, k\}$.

In words: $\mathbf{T}$ is the convex combination, with weights $1-t$ and t, of doing nothing and swapping two coordinates. Applied to a vector,

$$\begin{aligned}(\mathbf{Ty})_j &= (1-t)y_j + ty_k,\\ (\mathbf{Ty})_k &= ty_j + (1-t)y_k,\\ (\mathbf{Ty})_i &= y_i \qquad (i \neq j, k).\end{aligned} \tag{20.1.1}$$

The two moved entries are averages of the old y_j and y_k, with the **same** pair of weights used in both slots, exchanged. In particular $(\mathbf{Ty})_j + (\mathbf{Ty})_k = y_j + y_k$: a T-transform conserves the total, and indeed conserves the total of the pair it touches.

The first thing to check is that these matrices belong in the discussion at all.

Proposition 20.1.1 — T-transforms Are Doubly Stochastic

Every T-transform lies in Ω_n.

Proof. Let $\mathbf{T} = (1-t)\mathbf{I} + t\mathbf{Q}$ with $0 \le t \le 1$, and let $\{j, k\}$ be the pair $\mathbf{Q}$ interchanges. In the two positions (j, j) and (k, k) the entry of $\mathbf{T}$ is $1 - t$, in the two positions (j, k) and (k, j) it is t, in the remaining $n - 2$ diagonal positions both $\mathbf{I}$ and $\mathbf{Q}$ carry a 1, so the entry is 1, and everywhere else it is 0. Each entry is therefore 1, $1 - t$, t or 0, hence non-negative, since $t \ge 0$ and $1 - t \ge 0$. A permutation matrix has exactly one 1 in each row and each column and zeros elsewhere (the remark after Definition 2.6.2), so $\mathbf{Q1} = \mathbf{1}$ and $\mathbf{1}^\top\mathbf{Q} = \mathbf{1}^\top$; the same is true of $\mathbf{I}$, which is the permutation matrix of the identity permutation. Hence

$$\mathbf{T1} = (1-t)\mathbf{1} + t\mathbf{1} = \mathbf{1}, \qquad \mathbf{1}^\top\mathbf{T} = (1-t)\mathbf{1}^\top + t\mathbf{1}^\top = \mathbf{1}^\top,$$

which says that every row and every column of $\mathbf{T}$ adds up to 1. By Definition 17.8.4, $\mathbf{T} \in \Omega_n$.

■

Example. (Three T-transforms, and two impostors)

Take $n = 3$ and $\mathbf{y} = (6, 3, 0)$.

(a) Compute $\mathbf{Ty}$ for the T-transform on $\{1, 3\}$ with $t = \frac{1}{3}$, and for the ones with $t = 0$ and $t = 1$.

(b) Is the matrix $\frac{1}{2}(\mathbf{I} + \mathbf{P})$, with $\mathbf{P}$ the permutation matrix of the 3-cycle $1 \mapsto 2 \mapsto 3 \mapsto 1$, a T-transform?

(c) Is $-\mathbf{I} + 2\mathbf{Q}$, with $\mathbf{Q}$ the transposition matrix of $\{1, 2\}$, a T-transform?

Solution.

(a) With $j = 1$, $k = 3$ and $t = \frac{1}{3}$, Eq. 20.1.1 gives

$$\mathbf{Ty} = \left(\tfrac{2}{3}\cdot 6 + \tfrac{1}{3}\cdot 0,\ 3,\ \tfrac{1}{3}\cdot 6 + \tfrac{2}{3}\cdot 0\right) = (4, 3, 2).$$

At $t = 0$, $\mathbf{T} = \mathbf{I}$ and $\mathbf{Ty} = \mathbf{y}$; at $t = 1$, $\mathbf{T} = \mathbf{Q}$ and $\mathbf{Ty} = (0, 3, 6)$. So the endpoints of the family are "do nothing" and "swap".

(b) No. It is doubly stochastic, by the computation in Proposition 20.1.1 with $\mathbf{Q}$ re-

placed by $\mathbf{P}$, but Definition 20.1.1 asks for the permutation matrix of a **transposition**. Concretely, $\frac{1}{2}(\mathbf{I}+\mathbf{P})$ changes all three coordinates of $\mathbf{y}$, while a T-transform fixes at least $n-2$ of them.

(c) No: $t=2$ is outside $[0,1]$, and the matrix has the entry -1 in position $(1,1)$, so it is not even doubly stochastic. Applied to $\mathbf{y}$ it gives $(0,9,0)$, whose first two entries are further apart than 6 and 3: with $t \notin [0,1]$ the "average" is not between the two numbers, and the move spreads rather than evens.

Quick check. Let $\mathbf{T}$ be the T-transform on $\{1,2\}$ with $t=\frac{1}{4}$, and let $\mathbf{y}=(8,4,1)$. Compute $\mathbf{Ty}$, and verify $\mathbf{Ty} \prec \mathbf{y}$ directly from Definition 16.8.1.

Solution. $(\mathbf{Ty})_1 = \frac{3}{4}\cdot 8 + \frac{1}{4}\cdot 4 = 7$ and $(\mathbf{Ty})_2 = \frac{1}{4}\cdot 8 + \frac{3}{4}\cdot 4 = 5$, so $\mathbf{Ty}=(7,5,1)$. Both vectors are decreasing with total 13, and the running totals are $7, 12$ against $8, 12$. Since $7 \le 8$ and $12 \le 12$, (M1) holds, and (M2) is the equal totals. So $\mathbf{Ty} \prec \mathbf{y}$, as Proposition 18.7.6 already promised, since $\mathbf{T} \in \Omega_n$.

Warning. **A product of T-transforms is usually not a T-transform.** T-transforms are doubly stochastic, and so are their products (this is checked inside the proof of the main theorem below), but the product of two of them can move every coordinate. Averaging coordinates 1 and 2, then coordinates 2 and 3, changes all three. The theorem below produces a product, not a single T-transform.

20.1.3 One averaging step

Now the engine. Given $\mathbf{x} \prec \mathbf{y}$, we want to push $\mathbf{y}$ toward $\mathbf{x}$ by one T-transform, and we want a measure of progress that cannot stall. The measure is the number of coordinates in which the two vectors already agree.

Lemma 20.1.2 — One Averaging Step

Let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ be **decreasing**, with $\mathbf{x} \prec \mathbf{y}$ and $\mathbf{x} \neq \mathbf{y}$. Then there is a T-transform $\mathbf{T}$ such that $\mathbf{y}' = \mathbf{Ty}$ satisfies

(a) $\mathbf{y}'$ is decreasing;
(b) $\mathbf{x} \prec \mathbf{y}'$;
(c) $y'_i = x_i$ for strictly more indices i than $y_i = x_i$ does.

Idea. Both vectors are sorted, so compare them entry by entry. Somewhere $\mathbf{y}$ is too big and somewhere it is too small. Let j be the **last** place where $\mathbf{y}$ is too big and k the **first** place after j where it is too small; between them the two vectors already agree. Averaging coordinates j and k moves y_j down and y_k up by the same amount, and we move by exactly as much as the tighter of the two deficits allows, so that one of the two positions lands on $\mathbf{x}$ exactly. Two things then need checking, and they are not equally hard. The partial sums are the easy one: the only ones that drop are those between j and k, and they have slack at least $y_j - x_j$ to give away, while we give away no more than that. The delicate one is that $\mathbf{y}'$ must come out **decreasing**, since otherwise the lemma cannot be applied to it again; that is what taking j last buys, because it makes

the entries between j and k agree with $\mathbf{x}$'s.

Proof. Write $X_m = x_1 + \cdots + x_m$ and $Y_m = y_1 + \cdots + y_m$, with $X_0 = Y_0 = 0$. Since both vectors are decreasing, Definition 16.8.1 says $X_m \le Y_m$ for $m = 1, \dots, n-1$ and $X_n = Y_n$.

Step 1: the two indices. Some index has $y_i > x_i$: otherwise $y_i \le x_i$ for every i, and since $\mathbf{x} \neq \mathbf{y}$ at least one inequality is strict, so $Y_n < X_n$, contradicting $X_n = Y_n$. Let j be the **largest** index with $y_j > x_j$.

Next, some index $i > j$ has $y_i < x_i$. Suppose not. By the choice of j, $y_i \le x_i$ for every $i > j$; so $y_i = x_i$ for every $i > j$, and subtracting these from $X_n = Y_n$ gives $X_j = Y_j$. Then

$$X_{j-1} = X_j - x_j > Y_j - y_j = Y_{j-1},$$

because $x_j < y_j$. For $j \ge 2$ this contradicts $X_{j-1} \le Y_{j-1}$, and for $j = 1$ it reads $0 > 0$, which is false. So we may let k be the **smallest** index with $k > j$ and $y_k < x_k$.

By the maximality of j we have $y_i \ge x_i$ for $j < i < k$, and by the minimality of k we have $y_i \le x_i$ there. Hence

$$y_i = x_i \qquad (j < i < k). \tag{$*$}$$

Step 2: the transform. Put

$$\delta = \min\{\, y_j - x_j,\ x_k - y_k \,\} > 0.$$

Since $\mathbf{x}$ is decreasing and $j < k$, $x_j \ge x_k$, so

$$y_j > x_j \ge x_k > y_k,$$

and in particular $y_j - y_k > 0$. Also $\delta \le y_j - x_j \le y_j - y_k$, using $x_j \ge x_k > y_k$. So

$$t = \frac{\delta}{y_j - y_k}$$

satisfies $0 < t \le 1$, and Definition 20.1.1 gives a T-transform $\mathbf{T}$ acting on $\{j, k\}$ with this t. By Eq. 20.1.1,

$$y'_j = y_j - t(y_j - y_k) = y_j - \delta, \qquad y'_k = y_k + \delta,$$

and $y'_i = y_i$ for every other i.

Step 3: (c), the count. By the choice of δ, either $\delta = y_j - x_j$, and then $y'_j = x_j$; or $\delta = x_k - y_k$, and then $y'_k = x_k$. So $\mathbf{y}'$ agrees with $\mathbf{x}$ in at least one of the positions j, k. Neither position agreed before, since $y_j > x_j$ and $y_k < x_k$. Every other position is untouched. Hence the number of agreements strictly increases.

Step 4: (a), the sorted order. Only positions j and k change, and $\delta > 0$ lowers y_j and raises y_k. From $\delta \le y_j - x_j$ and $\delta \le x_k - y_k$,

$$y'_j \ge x_j, \qquad y'_k \le x_k.$$

If $j \ge 2$, then $y'_{j-1} = y_{j-1} \ge y_j > y'_j$. If $j + 1 < k$, then $y'_{j+1} = y_{j+1} = x_{j+1}$ by $(*)$, and $x_{j+1} \le x_j \le y'_j$. If $j + 1 = k$, then $y'_{j+1} = y'_k \le x_k \le x_j \le y'_j$. Symmetrically, if $k - 1 > j$ then $y'_{k-1} = x_{k-1} \ge x_k \ge y'_k$, and if $k \le n - 1$ then $y'_{k+1} = y_{k+1} \le y_k < y'_k$.

Every remaining consecutive pair consists of two untouched entries of the decreasing $\mathbf{y}$. So $\mathbf{y}'$ is decreasing.

Step 5: (b), the majorization. Write $Y'_m = y'_1 + \cdots + y'_m$. Since $\mathbf{y}'$ differs from $\mathbf{y}$ only at j and k, by $-\delta$ and $+\delta$,

$$Y'_m = \begin{cases} Y_m - \delta & (j \le m \le k-1), \\ Y_m & (\text{otherwise}). \end{cases}$$

In particular $Y'_n = Y_n = X_n$, which is (M2). For $m < j$ and for $m \ge k$ we have $Y'_m = Y_m \ge X_m$, which is (M1) there. For $j \le m \le k-1$, the identity $(*)$ gives $y_i = x_i$ for $j < i \le m$, hence

$$Y_m - X_m = Y_j - X_j.$$

Now $Y_j - X_j = (Y_{j-1} - X_{j-1}) + (y_j - x_j) \ge y_j - x_j \ge \delta$, using $Y_{j-1} \ge X_{j-1}$ (which is (M1), or $0 \ge 0$ when $j = 1$) and the definition of δ. Therefore

$$Y'_m - X_m = (Y_m - X_m) - \delta = (Y_j - X_j) - \delta \ge 0,$$

which is (M1) at m. So $\mathbf{x} \prec \mathbf{y}'$. This proves the lemma.

■

The choice of the two indices is the only delicate part, and it is worth saying why the obvious alternative fails, and where. Suppose j were taken as the *smallest* index with $y_j > x_j$, keeping k as the smallest index after j with $y_k < x_k$. Step 5 would survive: the minimality of k still gives $y_i \ge x_i$ for $j < i < k$, so the slack $Y_m - X_m$ is non-decreasing on $j \le m \le k-1$ instead of constant, and it is therefore at least its value $Y_j - X_j \ge y_j - x_j \ge \delta$ at $m = j$. What breaks is Step 4. The entries strictly between j and k need no longer agree with $\mathbf{x}$'s, and lowering y_j by δ can push it below y_{j+1}, so that $\mathbf{y}'$ comes out unsorted and Lemma 20.1.2 cannot be applied to it a second time. Take $\mathbf{x} = (5, 5, 0)$ and $\mathbf{y} = (6, 6, -2)$, both decreasing, with $\mathbf{x} \prec \mathbf{y}$ since $5 \le 6$, $10 \le 12$ and both totals are 10. Choosing j smallest gives $j = 1$ and $k = 3$, so $\delta = \min\{6-5,\ 0-(-2)\} = 1$ and $\mathbf{y}' = (5, 6, -1)$, which is not decreasing; the rule of the lemma gives $j = 2$ instead, and $\mathbf{y}' = (6, 5, -1)$, which is. Taking j last and k first after it makes the interval between them a stretch where the two vectors already coincide, and that stretch is what protects the order.

20.1.4 The theorem

Theorem 20.1.3 — Hardy–Littlewood–Pólya Theorem

Let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$. Then

$$\mathbf{x} \prec \mathbf{y} \quad \Longleftrightarrow \quad \mathbf{x} = \mathbf{D}\mathbf{y} \ \text{ for some } \mathbf{D} \in \Omega_n.$$

Moreover, if $\mathbf{x}$ and $\mathbf{y}$ are both decreasing, $\mathbf{D}$ may be taken to be a product of at most $n-1$ T-transforms.

Idea. ($\Leftarrow$) is Chapter 18's Proposition 18.7.6 and needs nothing new.

For ($\Rightarrow$), sort both vectors first, since neither side of the equivalence sees the order.

Then count agreements. Lemma 20.1.2 raises that count by at least one, keeps both hypotheses alive, and therefore may be applied again; the count is at most n, so the process stops, at $\mathbf{y}$ turned into $\mathbf{x}$. The bound $n-1$ comes from noticing that the count can never be exactly $n-1$: two vectors with equal totals that agree in all but one coordinate agree in that one too.

Proof. ($\Leftarrow$) If $\mathbf{x} = \mathbf{D}\mathbf{y}$ with $\mathbf{D} \in \Omega_n$, then $\mathbf{x} \prec \mathbf{y}$ by Proposition 18.7.6.

($\Rightarrow$) Suppose $\mathbf{x} \prec \mathbf{y}$.

Step 1: the decreasing case. Assume first that $\mathbf{x}$ and $\mathbf{y}$ are both decreasing. For $\mathbf{u}, \mathbf{v} \in \mathbb{R}^n$ write $\operatorname{dis}(\mathbf{u}, \mathbf{v})$ for the number of indices i with $u_i \neq v_i$. We claim:

> *Claim.* If $\mathbf{x}$ and $\mathbf{y}$ are decreasing with $\mathbf{x} \prec \mathbf{y}$ and $d = \operatorname{dis}(\mathbf{x}, \mathbf{y})$, then $\mathbf{x} = \mathbf{T}_r \cdots \mathbf{T}_1 \mathbf{y}$ for some T-transforms $\mathbf{T}_1, \dots, \mathbf{T}_r$ with $r = 0$ if $d = 0$, and $r \leq d - 1$ otherwise.
>
> > *Proof.* First, $d \neq 1$: if $\mathbf{x}$ and $\mathbf{y}$ agreed in all indices but one, say i_0, then subtracting those $n-1$ equalities from the equal totals (M2) would give $x_{i_0} = y_{i_0}$ too, so $d = 0$. We induct on d.
> >
> > If $d = 0$ then $\mathbf{x} = \mathbf{y}$, and the empty product, $r = 0$, works. Let $d \geq 2$, and assume the claim for every smaller value. By Lemma 20.1.2 there is a T-transform $\mathbf{T}_1$ with $\mathbf{y}' = \mathbf{T}_1 \mathbf{y}$ decreasing, $\mathbf{x} \prec \mathbf{y}'$ and $d' = \operatorname{dis}(\mathbf{x}, \mathbf{y}') \leq d - 1$. If $d' = 0$, then $\mathbf{x} = \mathbf{T}_1 \mathbf{y}$ and $r = 1 \leq d - 1$. Otherwise $d' \geq 2$, since $d' \neq 1$ by the first paragraph applied to $\mathbf{x}$ and $\mathbf{y}'$; the inductive hypothesis gives $\mathbf{x} = \mathbf{T}_r \cdots \mathbf{T}_2 \mathbf{y}'$ with $r - 1 \leq d' - 1$, so $r \leq d' \leq d - 1$. This proves the claim. ∎

Since $d \leq n$, the claim gives $r \leq d - 1 \leq n - 1$ in every case. This proves the "moreover" clause.

Step 2: products stay doubly stochastic. If $\mathbf{A}, \mathbf{B} \in \Omega_n$, then $\mathbf{AB}$ has non-negative entries, and $\mathbf{AB1} = \mathbf{A1} = \mathbf{1}$, $\mathbf{1}^\top \mathbf{AB} = \mathbf{1}^\top \mathbf{B} = \mathbf{1}^\top$; so $\mathbf{AB} \in \Omega_n$ by Definition 17.8.4. By induction, any finite product of doubly stochastic matrices is doubly stochastic. With Proposition 20.1.1, the matrix $\mathbf{D}_0 = \mathbf{T}_r \cdots \mathbf{T}_1$ of Step 1 lies in Ω_n.

Step 3: the general case. Let $\mathbf{x} \prec \mathbf{y}$ be arbitrary. Majorization sees only rearrangements (the remark after Definition 16.8.1), so $\mathbf{x}^{\downarrow} \prec \mathbf{y}^{\downarrow}$, and Step 1 gives $\mathbf{D}_0 \in \Omega_n$ with $\mathbf{x}^{\downarrow} = \mathbf{D}_0 \mathbf{y}^{\downarrow}$. Choose permutations $\sigma, \tau \in S_n$ with $\mathbf{y}^{\downarrow} = \mathbf{P}_\sigma \mathbf{y}$ and $\mathbf{x} = \mathbf{P}_\tau \mathbf{x}^{\downarrow}$; these exist because $\mathbf{y}^{\downarrow}$ is a rearrangement of $\mathbf{y}$ and $\mathbf{x}$ of $\mathbf{x}^{\downarrow}$. Each $\mathbf{P}_\sigma$ is doubly stochastic, having exactly one 1 in each row and each column and zeros elsewhere (the remark after Definition 2.6.2), so by Step 2

$$\mathbf{D} = \mathbf{P}_\tau \mathbf{D}_0 \mathbf{P}_\sigma \in \Omega_n, \qquad \mathbf{D}\mathbf{y} = \mathbf{P}_\tau \mathbf{D}_0 \mathbf{y}^{\downarrow} = \mathbf{P}_\tau \mathbf{x}^{\downarrow} = \mathbf{x}.$$

This proves the theorem. ∎

Two remarks on what the theorem does and does not say. It converts a family of $n-1$ inequalities

and one equality into a single algebraic identity $\mathbf{x} = \mathbf{D}\mathbf{y}$, and an identity is much easier to feed into another argument, as the next section does, one row of $\mathbf{D}$ at a time. And the $n-1$ in the "moreover" clause is sharp; Exercise (C3: The count $n-1$ cannot be improved) exhibits a pair needing that many.

Remark. The word **decreasing** in the "moreover" clause is not decoration. For $\mathbf{y} = (6,4,2,0)$ and the unsorted $\mathbf{x} = (\frac{3}{2}, 1, \frac{9}{2}, 5)$ we have $\mathbf{x} \prec \mathbf{y}$, since $\mathbf{x}^{\downarrow} = (5, \frac{9}{2}, \frac{3}{2}, 1)$ has running totals $5, \frac{19}{2}, 11$ against $6, 10, 12$ and both totals are 12; yet no product of three T-transforms equals $\mathbf{x}$, since for each of the finitely many choices of the three pairs the best the three parameters can do still misses it. Four transforms suffice: the transforms on $\{1,2\}$, $\{3,4\}$, $\{1,3\}$, $\{2,4\}$ with $t = \frac{1}{2}, \frac{1}{2}, \frac{7}{8}, 1$ carry $\mathbf{y}$ through $(5,5,2,0)$, $(5,5,1,1)$ and $(\frac{3}{2}, 5, \frac{9}{2}, 1)$ to $\mathbf{x}$. Step 3 of the proof handles an unsorted pair with permutations instead, and a permutation matrix is a T-transform only when it is a transposition.

Example. (Four coordinates, two transforms)

Let $\mathbf{y} = (7,5,3,1)$ and $\mathbf{x} = (5,5,4,2)$. Verify $\mathbf{x} \prec \mathbf{y}$, run the construction of Theorem 20.1.3, and write out the resulting $\mathbf{D}$.

Solution. Both vectors are decreasing with total 16, and the running totals are $5, 10, 14$ for $\mathbf{x}$ against $7, 12, 15$ for $\mathbf{y}$. So (M1) and (M2) hold and $\mathbf{x} \prec \mathbf{y}$.

First step. Here $\mathbf{y} - \mathbf{x} = (2, 0, -1, -1)$, so the only index with $y_i > x_i$ is $i = 1$, giving $j = 1$; the smallest index above it with $y_i < x_i$ is $k = 3$. Then

$$\delta = \min\{7-5,\ 4-3\} = 1, \qquad t = \frac{1}{7-3} = \tfrac{1}{4},$$

and $\mathbf{T}_1$ is the T-transform on $\{1,3\}$ with $t = \frac{1}{4}$:

$$\mathbf{y}' = \mathbf{T}_1\mathbf{y} = \left(\tfrac{3}{4}\cdot 7 + \tfrac{1}{4}\cdot 3,\ 5,\ \tfrac{1}{4}\cdot 7 + \tfrac{3}{4}\cdot 3,\ 1\right) = (6,5,4,1).$$

Now $\mathbf{y}'$ agrees with $\mathbf{x}$ in positions 2 and 3, where before it agreed only in position 2.

Second step. $\mathbf{y}' - \mathbf{x} = (1, 0, 0, -1)$, so $j = 1$ and $k = 4$, with $\delta = \min\{1,1\} = 1$ and $t = 1/(6-1) = \frac{1}{5}$. The T-transform $\mathbf{T}_2$ on $\{1,4\}$ gives

$$\mathbf{T}_2\mathbf{y}' = \left(\tfrac{4}{5}\cdot 6 + \tfrac{1}{5}\cdot 1,\ 5,\ 4,\ \tfrac{1}{5}\cdot 6 + \tfrac{4}{5}\cdot 1\right) = (5,5,4,2) = \mathbf{x}.$$

Two transforms, and $2 \le n - 1 = 3$.

The matrix. Multiplying $\mathbf{T}_2\mathbf{T}_1$ row by row,

$$\mathbf{D} = \mathbf{T}_2\mathbf{T}_1 = \begin{pmatrix} \frac{3}{5} & 0 & \frac{1}{5} & \frac{1}{5} \\ 0 & 1 & 0 & 0 \\ \frac{1}{4} & 0 & \frac{3}{4} & 0 \\ \frac{3}{20} & 0 & \frac{1}{20} & \frac{4}{5} \end{pmatrix}.$$

Every row adds up to 1, and so does every column: the first is $\frac{3}{5} + \frac{1}{4} + \frac{3}{20} = \frac{12+5+3}{20} = 1$, the third is $\frac{1}{5} + \frac{3}{4} + \frac{1}{20} = \frac{4+15+1}{20} = 1$, and the second and fourth are visibly 1. Finally

$$\mathbf{D}\mathbf{y} = \left(\tfrac{21+3+1}{5},\ 5,\ \tfrac{7+9}{4},\ \tfrac{21+3+16}{20}\right) = (5,5,4,2) = \mathbf{x}.$$

Note that $\mathbf{D}$ is not a T-transform: it moves three of the four coordinates.

Warning. **The matrix $\mathbf{D}$ is far from unique, and "doubly stochastic" cannot be relaxed to "row-stochastic".** For $\mathbf{y} = (2, 1, 0)$ and $\mathbf{x} = (1, 1, 1)$, both

$$\mathbf{D}_1 = \tfrac{1}{3}\mathbf{J}, \qquad \mathbf{D}_2 = \begin{pmatrix} 0 & 1 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} \\ \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix}$$

are doubly stochastic with $\mathbf{D}_i\mathbf{y} = \mathbf{x}$. And if only the **rows** are required to add up to 1, the conclusion fails: with $\mathbf{y} = (1, 0)$ and the row-stochastic $\mathbf{S} = \left(\begin{smallmatrix} 1 & 0 \\ 1 & 0 \end{smallmatrix}\right)$, $\mathbf{Sy} = (1, 1)$, whose total is $2 \neq 1$, so $\mathbf{Sy} \not\prec \mathbf{y}$. The column condition is what enforces the equal totals.

20.1.5 Majorization as a polytope

Birkhoff's theorem turns the doubly stochastic matrix of Theorem 20.1.3 into an average of permutations, and the statement becomes geometric.

Corollary 20.1.4 — Majorization Is Membership in a Permutation Polytope

Let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$. Then

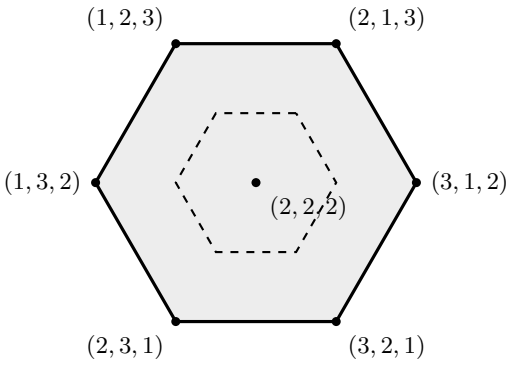
$$\mathbf{x} \prec \mathbf{y} \quad \Longleftrightarrow \quad \mathbf{x} \in \operatorname{conv}\{\mathbf{P}_\sigma \mathbf{y} : \sigma \in S_n\}.$$

Proof. ($\Rightarrow$) By Theorem 20.1.3, $\mathbf{x} = \mathbf{D}\mathbf{y}$ with $\mathbf{D} \in \Omega_n$. By Theorem 18.7.2, $\mathbf{D} \in \operatorname{conv}\{\mathbf{P}_\sigma : \sigma \in S_n\}$, so by Theorem 17.1.3, $\mathbf{D} = \sum_{i=1}^{m} t_i \mathbf{P}_{\sigma_i}$ with $t_i \geq 0$ and $\sum_i t_i = 1$. Hence $\mathbf{x} = \sum_i t_i \mathbf{P}_{\sigma_i}\mathbf{y}$, a convex combination of the vectors $\mathbf{P}_\sigma\mathbf{y}$, which lies in their convex hull by Theorem 17.1.3.

($\Leftarrow$) By Theorem 17.1.3, $\mathbf{x} = \sum_i t_i \mathbf{P}_{\sigma_i}\mathbf{y}$ with $(t_1, \ldots, t_m)$ a list of non-negative weights adding up to 1. Put $\mathbf{D} = \sum_i t_i \mathbf{P}_{\sigma_i}$. Its entries are non-negative, and $\mathbf{D1} = \sum_i t_i \mathbf{1} = \mathbf{1}$, $\mathbf{1}^\top \mathbf{D} = \mathbf{1}^\top$, so $\mathbf{D} \in \Omega_n$ and $\mathbf{x} = \mathbf{D}\mathbf{y}$. By Proposition 18.7.6, $\mathbf{x} \prec \mathbf{y}$.

■

The set $\operatorname{conv}\{\mathbf{P}_\sigma \mathbf{y}\}$ is the **permutation polytope** of $\mathbf{y}$: the convex hull of the $n!$ rearrangements of $\mathbf{y}$. It lies in the affine subspace where the coordinate sum equals $\sum_i y_i$, so its dimension is at most $n - 1$. For $n = 3$ and distinct entries it is a hexagon.



The solid hexagon is the permutation polytope of $\mathbf{y} = (3, 2, 1)$, drawn inside the plane $x_1 + x_2 + x_3 = 6$; the dashed one, at half the size, is the polytope of $(\frac{5}{2}, 2, \frac{3}{2})$. By Corollary 20.1.4, $\mathbf{x} \prec \mathbf{y}$ says that $\mathbf{x}$ lies in the solid hexagon, and $\mathbf{x} \prec (\frac{5}{2}, 2, \frac{3}{2}) \prec \mathbf{y}$ says that the dashed hexagon sits inside the solid one. *The majorization order is containment of permutation polytopes.* The center $(2, 2, 2)$, the flat vector, lies in every one of them, which is Example (A chain, the two extremes, and size one) (b) again.

> *Quick check.* Use Corollary 20.1.4 to give a second proof that $\{\mathbf{x} : \mathbf{x} \prec \mathbf{y}\}$ is convex, a fact Chapter 17 proved by hand in Example (The vectors majorized by a fixed vector).

> *Solution.* By the corollary, $\{\mathbf{x} : \mathbf{x} \prec \mathbf{y}\} = \operatorname{conv}\{\mathbf{P}_\sigma \mathbf{y} : \sigma \in S_n\}$. A convex hull is convex (Theorem 17.1.3, or Definition 17.1.4 directly). So the set is convex.

20.1.6 Exercises

20.1.6.1 A. Check your understanding

Exercise A1.

(a) Define a T-transform, and say which coordinates of a vector it can change.

(b) State the Hardy–Littlewood–Pólya theorem in full.

(c) True or false: if $\mathbf{x} = \mathbf{S}\mathbf{y}$ with $\mathbf{S}$ row-stochastic (non-negative entries, every row adding up to 1), then $\mathbf{x} \prec \mathbf{y}$. Justify your answer.

(d) True or false: if $\mathbf{x} \prec \mathbf{y}$, the doubly stochastic $\mathbf{D}$ with $\mathbf{x} = \mathbf{D}\mathbf{y}$ is unique. Justify your answer.

(e) In Lemma 20.1.2, why is j chosen as the **largest** index with $y_j > x_j$ rather than the smallest?

(f) Why can the number of coordinates in which two decreasing vectors $\mathbf{x} \prec \mathbf{y}$ agree never be exactly $n - 1$?

Solution.

(a) For $1 \le j < k \le n$ and $0 \le t \le 1$, it is $\mathbf{T} = (1 - t)\mathbf{I} + t\mathbf{Q}$ with $\mathbf{Q}$ the permutation matrix of the transposition of j and k (Definition 20.1.1). It changes only the coordinates j and k, replacing each by an average of the two old values.

(b) For $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$, $\mathbf{x} \prec \mathbf{y}$ if and only if $\mathbf{x} = \mathbf{D}\mathbf{y}$ for some doubly stochastic $\mathbf{D}$; and when $\mathbf{x}$ and $\mathbf{y}$ are both decreasing, $\mathbf{D}$ may be taken to be a product of at most $n - 1$ T-transforms (Theorem 20.1.3).

(c) False. With $\mathbf{y} = (1, 0)$ and $\mathbf{S} = \left(\begin{smallmatrix} 1 & 0 \\ 1 & 0 \end{smallmatrix}\right)$, $\mathbf{S}\mathbf{y} = (1, 1)$ has total 2 while $\mathbf{y}$ has total 1, so (M2) fails. Row sums alone control nothing but the individual entries; the column sums are what preserve the total.

(d) False. For $\mathbf{y} = (2, 1, 0)$ and $\mathbf{x} = (1, 1, 1)$, both $\frac{1}{3}\mathbf{J}$ and the matrix $\mathbf{D}_2$ of the warning after Example (Four coordinates, two transforms) send $\mathbf{y}$ to $\mathbf{x}$.

(e) Because it makes the entries strictly between j and k agree with $\mathbf{x}$'s, which is what Step 4 needs in order to keep $\mathbf{y}'$ decreasing. The majorization would survive the other choice: with j smallest, the slack $Y_m - X_m$ is non-decreasing on $j \le m \le k-1$ rather than constant, hence still at least δ throughout, and Step 5 goes through.

The sorted order is what fails, and with it the possibility of applying the lemma again. For $\mathbf{x} = (5, 5, 0)$ and $\mathbf{y} = (6, 6, -2)$, taking j smallest gives $j = 1$, $k = 3$, $\delta = 1$ and $\mathbf{y}' = (5, 6, -1)$, which is not decreasing, while the rule of the lemma gives $j = 2$ and $\mathbf{y}' = (6, 5, -1)$, which is.

(f) Suppose they agree in all indices but i_0. Subtracting the $n - 1$ equalities $x_i = y_i$ from the equal totals of (M2) leaves $x_{i_0} = y_{i_0}$, so in fact they agree everywhere.

20.1.6.2 B. Practice

Exercise B1: Run the construction.

Let $\mathbf{y} = (9, 5, 4)$ and $\mathbf{x} = (6, 6, 6)$. Verify $\mathbf{x} \prec \mathbf{y}$, produce T-transforms $\mathbf{T}_1, \mathbf{T}_2$ with $\mathbf{x} = \mathbf{T}_2\mathbf{T}_1\mathbf{y}$ by the recipe of Lemma 20.1.2, and write out $\mathbf{D} = \mathbf{T}_2\mathbf{T}_1$. Hence check that $\mathbf{D}$ is doubly stochastic.

Solution. Both vectors are decreasing with total 18, and the running totals are $6, 12$ against $9, 14$. So (M1) and (M2) hold and $\mathbf{x} \prec \mathbf{y}$.

First step. $\mathbf{y} - \mathbf{x} = (3, -1, -2)$, so $j = 1$ and $k = 2$. Then $\delta = \min\{3, 1\} = 1$ and $t = 1/(9 - 5) = \frac{1}{4}$, and $\mathbf{T}_1$ acts on $\{1, 2\}$:

$$\mathbf{y}' = \left(\tfrac{3}{4} \cdot 9 + \tfrac{1}{4} \cdot 5,\ \tfrac{1}{4} \cdot 9 + \tfrac{3}{4} \cdot 5,\ 4\right) = (8, 6, 4).$$

Second step. $\mathbf{y}' - \mathbf{x} = (2, 0, -2)$, so $j = 1$, $k = 3$, $\delta = \min\{2, 2\} = 2$ and $t = 2/(8-4) = \frac{1}{2}$. Then

$$\mathbf{T}_2\mathbf{y}' = \left(\tfrac{1}{2} \cdot 8 + \tfrac{1}{2} \cdot 4,\ 6,\ \tfrac{1}{2} \cdot 8 + \tfrac{1}{2} \cdot 4\right) = (6, 6, 6) = \mathbf{x}.$$

The matrix. $\mathbf{T}_1$ has rows $(\frac{3}{4}, \frac{1}{4}, 0)$, $(\frac{1}{4}, \frac{3}{4}, 0)$, $(0, 0, 1)$, and $\mathbf{T}_2$ has rows $(\frac{1}{2}, 0, \frac{1}{2})$, $(0, 1, 0)$, $(\frac{1}{2}, 0, \frac{1}{2})$. Multiplying,

$$\mathbf{D} = \mathbf{T}_2\mathbf{T}_1 = \begin{pmatrix} \frac{3}{8} & \frac{1}{8} & \frac{1}{2} \\ \frac{1}{4} & \frac{3}{4} & 0 \\ \frac{3}{8} & \frac{1}{8} & \frac{1}{2} \end{pmatrix}.$$

Each row adds up to 1, and the columns add up to $\frac{3}{8} + \frac{1}{4} + \frac{3}{8} = 1$, $\frac{1}{8} + \frac{3}{4} + \frac{1}{8} = 1$ and $\frac{1}{2} + 0 + \frac{1}{2} = 1$. So $\mathbf{D} \in \Omega_3$, and $\mathbf{D}\mathbf{y} = (\frac{27}{8} + \frac{5}{8} + 2,\ \frac{9}{4} + \frac{15}{4},\ \frac{27}{8} + \frac{5}{8} + 2) = (6, 6, 6)$.

Exercise B2: Determine which are majorizations.

For each pair, determine whether $\mathbf{x} \prec \mathbf{y}$. Where it holds, exhibit a doubly stochastic $\mathbf{D}$ with $\mathbf{x} = \mathbf{D}\mathbf{y}$; where it fails, name the clause of Definition 16.8.1 and the value of k at which it fails. Justify your answer.

(a) $\mathbf{x} = (2, 2, 2)$, $\mathbf{y} = (4, 1, 1)$.

(b) $\mathbf{x} = (3, 1, 0)$, $\mathbf{y} = (2, 2, 0)$.

(c) $\mathbf{x} = (1, 3, 0)$, $\mathbf{y} = (2, 0, 2)$.

(d) $\mathbf{x} = (1, 1)$, $\mathbf{y} = (2, 1)$.

Solution.

(a) Both decreasing, totals $6 = 6$; running totals $2, 4$ against $4, 5$. So $\mathbf{x} \prec \mathbf{y}$. Here $\mathbf{x}$ is the flat vector, and $\mathbf{D} = \frac{1}{3}\mathbf{J}$ works: every entry of $\frac{1}{3}\mathbf{J}\mathbf{y}$ is $\frac{1}{3}(4+1+1) = 2$.

(b) Totals $4 = 4$, but at $k = 1$ the sorted first entries are $3 > 2$, so (M1) fails at $k = 1$ and $\mathbf{x} \not\prec \mathbf{y}$.

(c) Sorted, $\mathbf{x}^{\downarrow} = (3, 1, 0)$ and $\mathbf{y}^{\downarrow} = (2, 2, 0)$; this is (b) again, so $\mathbf{x} \not\prec \mathbf{y}$, with (M1) failing at $k = 1$.

(d) Totals $2 \neq 3$, so (M2) fails and $\mathbf{x} \not\prec \mathbf{y}$. (Both running totals do satisfy (M1), so $\mathbf{x} \prec_w \mathbf{y}$.)

Exercise B3: Into the polytope.

Let $\mathbf{y} = (4, 2, 0)$ and $\mathbf{x} = (2, 2, 2)$. Using Corollary 20.1.4, write $\mathbf{x}$ explicitly as a convex combination of rearrangements of $\mathbf{y}$, in two different ways.

Solution. The six rearrangements of $\mathbf{y}$ are the vectors with entries $4, 2, 0$ in some order. Averaging the three cyclic shifts,

$$\tfrac{1}{3}\big[(4,2,0) + (0,4,2) + (2,0,4)\big] = \tfrac{1}{3}(6,6,6) = (2,2,2) = \mathbf{x}.$$

Alternatively, average a vector with its reversal:

$$\tfrac{1}{2}\big[(4,2,0) + (0,2,4)\big] = \tfrac{1}{2}(4,4,4) = (2,2,2) = \mathbf{x}.$$

Both are convex combinations, with weights $(\frac{1}{3}, \frac{1}{3}, \frac{1}{3})$ and $(\frac{1}{2}, \frac{1}{2})$. This is the non-uniqueness of the warning after Example (Four coordinates, two transforms), seen on the polytope: $\mathbf{x}$ is the center of the hexagon, lying strictly inside it rather than on an edge, and such a point has many representations. (The hexagon itself has empty interior in $\mathbb{R}^3$, since it lies in the plane $x_1 + x_2 + x_3 = 6$; "inside" here means inside the hexagon, within that plane.)

20.1.6.3 C. Going deeper

Exercise C1: Row-stochastic is not enough, twice over.

Let $\mathbf{S} \in M_n(\mathbb{R})$ be **row-stochastic**: every entry is non-negative and every row adds up to 1.

(a) Give such an $\mathbf{S}$ and a $\mathbf{y} \in \mathbb{R}^2$ with $\mathbf{S}\mathbf{y} \not\prec \mathbf{y}$.

(b) Prove that if $\mathbf{S}\mathbf{y} \prec \mathbf{y}$ for **every** $\mathbf{y} \in \mathbb{R}^n$, then $\mathbf{S}$ is doubly stochastic.

Hint for (b): test the hypothesis on the standard basis vectors.

Solution.

(a) Take $\mathbf{S} = \left(\begin{smallmatrix} 1 & 0 \\ 1 & 0 \end{smallmatrix}\right)$ and $\mathbf{y} = (1, 0)$. Then $\mathbf{S}\mathbf{y} = (1, 1)$, whose total is 2, while $\mathbf{y}$ has total 1. So (M2) fails.

(b) Apply the hypothesis with $\mathbf{y} = \mathbf{e}_j$. The vector $\mathbf{S}\mathbf{e}_j$ is the j-th column of $\mathbf{S}$, by

Definition 0.9.9. From $\mathbf{S}\mathbf{e}_j \prec \mathbf{e}_j$, clause (M2) gives

$$\sum_{i=1}^{n} s_{ij} = \sum_{i=1}^{n} (\mathbf{e}_j)_i = 1.$$

So every column of $\mathbf{S}$ adds up to 1. The entries are non-negative and the rows add up to 1 by hypothesis, so $\mathbf{S}$ is doubly stochastic by Definition 17.8.4.

Exercise C2: Transitivity, a second time.

(a) Prove that if $\mathbf{A}, \mathbf{B} \in \Omega_n$ then $\mathbf{AB} \in \Omega_n$.

(b) Hence deduce that $\mathbf{x} \prec \mathbf{y}$ and $\mathbf{y} \prec \mathbf{z}$ imply $\mathbf{x} \prec \mathbf{z}$, and compare this route with the proof of Proposition 16.8.1 (b).

Solution.

(a) The entries of $\mathbf{AB}$ are $\sum_k a_{ik} b_{kj}$, sums of products of non-negative numbers, hence non-negative. Since $\mathbf{A1} = \mathbf{1}$ and $\mathbf{B1} = \mathbf{1}$, we get $(\mathbf{AB})\mathbf{1} = \mathbf{A}(\mathbf{B1}) = \mathbf{A1} = \mathbf{1}$, so every row of $\mathbf{AB}$ adds up to 1. Since $\mathbf{1}^\top \mathbf{A} = \mathbf{1}^\top$ and $\mathbf{1}^\top \mathbf{B} = \mathbf{1}^\top$, we get $\mathbf{1}^\top(\mathbf{AB}) = (\mathbf{1}^\top \mathbf{A})\mathbf{B} = \mathbf{1}^\top \mathbf{B} = \mathbf{1}^\top$, so every column does too. By Definition 17.8.4, $\mathbf{AB} \in \Omega_n$.

(b) By Theorem 20.1.3 there are $\mathbf{D}, \mathbf{E} \in \Omega_n$ with $\mathbf{x} = \mathbf{D}\mathbf{y}$ and $\mathbf{y} = \mathbf{E}\mathbf{z}$. Then $\mathbf{x} = \mathbf{DE}\mathbf{z}$, and $\mathbf{DE} \in \Omega_n$ by (a). By Theorem 20.1.3 again, $\mathbf{x} \prec \mathbf{z}$.

Proposition 16.8.1 (b) proved the same thing in one line, by chaining the inequalities $X_k \le Y_k \le Z_k$ between running totals. That proof is shorter and uses nothing. The route here is longer, but it explains transitivity rather than verifying it: a majorization is an averaging, and averaging twice is averaging.

Exercise C3: The count $n-1$ cannot be improved.

Let $n \ge 2$, $\mathbf{y} = (n, 0, \dots, 0)$ and $\mathbf{x} = (1, 1, \dots, 1)$ in $\mathbb{R}^n$. For $\mathbf{z} \in \mathbb{R}^n$, write $\operatorname{supp}(\mathbf{z}) = \{i : z_i \neq 0\}$.

(a) Show that $\mathbf{x} \prec \mathbf{y}$.

(b) Let $\mathbf{T}$ be a T-transform. Prove that $|\operatorname{supp}(\mathbf{Tz})| \le |\operatorname{supp}(\mathbf{z})| + 1$ for every $\mathbf{z} \in \mathbb{R}^n$.

(c) Deduce that no product of fewer than $n-1$ T-transforms sends $\mathbf{y}$ to $\mathbf{x}$.

Solution.

(a) Both vectors are decreasing with total n. Every running total of $\mathbf{y}$ is n, and the k-th running total of $\mathbf{x}$ is $k \le n$. So (M1) and (M2) hold.

(b) Let $\mathbf{T}$ act on $\{j, k\}$ with parameter t. By Eq. 20.1.1, $(\mathbf{Tz})_i = z_i$ for $i \notin \{j, k\}$, so

$$\operatorname{supp}(\mathbf{Tz}) \subseteq \operatorname{supp}(\mathbf{z}) \cup \{j, k\}.$$

If both $j, k \in \operatorname{supp}(\mathbf{z})$, the right side is $\operatorname{supp}(\mathbf{z})$ and there is nothing to prove. If neither is, then $z_j = z_k = 0$, so $(\mathbf{Tz})_j = (\mathbf{Tz})_k = 0$ and again $\operatorname{supp}(\mathbf{Tz}) \subseteq \operatorname{supp}(\mathbf{z})$. In the remaining case exactly one of them, say j, lies in $\operatorname{supp}(\mathbf{z})$, and

then $\operatorname{supp}(\mathbf{Tz}) \subseteq \operatorname{supp}(\mathbf{z}) \cup \{k\}$, a set with one more element. In all cases the bound holds.

(c) Suppose $\mathbf{x} = \mathbf{T}_r \cdots \mathbf{T}_1 \mathbf{y}$. Put $\mathbf{z}^{(0)} = \mathbf{y}$ and $\mathbf{z}^{(i)} = \mathbf{T}_i \mathbf{z}^{(i-1)}$. Then $|\operatorname{supp}(\mathbf{z}^{(0)})| = 1$ and $|\operatorname{supp}(\mathbf{z}^{(r)})| = |\operatorname{supp}(\mathbf{x})| = n$. By (b), the size of the support grows by at most 1 at each step, so

$$n \le 1 + r, \qquad \text{that is,} \qquad r \ge n - 1.$$

Together with Theorem 20.1.3, which gives such a product with $r \le n-1$, exactly $n-1$ transforms are needed for this pair.

20.2 Convex Functions of a Majorization

Section 1 turned the n inequalities of a majorization into a single identity, $\mathbf{x} = \mathbf{Dy}$ with $\mathbf{D}$ doubly stochastic. This section spends it. Chapter 16 §07 left to this chapter "the general consequences of a majorization $\mathbf{x} \prec \mathbf{y}$, namely $\sum_i \phi(x_i) \le \sum_i \phi(y_i)$ for every convex $\phi\colon \mathbb{R} \to \mathbb{R}$, ..."; that is the first theorem below, and its converse says that the convex functions see nothing but the majorization. Two more promises are paid from it: Chapter 16 §08's claim that for non-negative vectors "$\mathbf{x} \prec \mathbf{y}$ implies $x_1 \cdots x_n \ge y_1 \cdots y_n$", and Chapters 17 §10 and §11's claim that "$\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A}) = \sum_i f(\lambda_i(\mathbf{A}))$ is convex on the Hermitian matrices with spectrum in that interval" for every convex f.

Conventions. Vectors are real and $\prec$, $\prec_w$ are Definition 16.8.1. A **convex** function is one in the sense of Definition 17.10.1, and an interval of $\mathbb{R}$ is a convex subset of $\mathbb{R}$, since it contains every number lying between two of its points. In the last subsection $F = \mathbb{R}$ or $\mathbb{C}$, matrices in $M_n(F)$ written $\mathbf{A}, \mathbf{B}, \mathbf{C}$ are **Hermitian**, and $f(\mathbf{A})$ is the spectral functional calculus of Chapter 11 §08, Definition 11.8.2. There $\mathbf{P}_j$, with an integer subscript, is an orthogonal projection of a spectral resolution; $\mathbf{P}_\sigma$ always means a permutation matrix. No analysis is imported here: the only facts used from outside linear algebra reach us through Chapter 17's already proved results.

20.2.1 Karamata's inequality

A majorization is a statement about sums of the largest entries. A convex function is one whose graph lies below its chords. The link between them is that an averaging matrix turns one into the other, and §01 says that a majorization *is* an averaging matrix.

Theorem 20.2.1 — Karamata's Inequality

Let $I \subseteq \mathbb{R}$ be an interval, let $\phi\colon I \to \mathbb{R}$ be **convex**, and let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ satisfy $\mathbf{x} \prec \mathbf{y}$, with every entry of $\mathbf{y}$ lying in I. Then every entry of $\mathbf{x}$ lies in I, and

$$\sum_{i=1}^{n} \phi(x_i) \;\le\; \sum_{i=1}^{n} \phi(y_i).$$

Idea. Write $\mathbf{x} = \mathbf{Dy}$ with $\mathbf{D}$ doubly stochastic. Each x_i is then a weighted average of the y_j, with the weights in row i of $\mathbf{D}$; Jensen's inequality bounds $\phi(x_i)$ by the same average of the $\phi(y_j)$. Add these n inequalities. The coefficient of $\phi(y_j)$ on the right is

the sum of column j of $\mathbf{D}$, which is 1. The rows and the columns do two different jobs, and this is where "doubly" earns its keep.

Proof. By Theorem 20.1.3 there is a doubly stochastic $\mathbf{D} = (d_{ij})$ with $\mathbf{x} = \mathbf{D}\mathbf{y}$, that is,

$$x_i = \sum_{j=1}^{n} d_{ij} y_j \qquad (i = 1, \dots, n).$$

Fix i. The numbers $d_{i1}, \dots, d_{in}$ are non-negative and add up to 1, since row i of $\mathbf{D}$ is a row of a doubly stochastic matrix (Definition 17.8.4). So x_i is a convex combination of $y_1, \dots, y_n$, all of which lie in the convex set I; by Lemma 17.1.2, $x_i \in I$. Now Theorem 17.10.2, applied to the convex ϕ on I with the points $y_1, \dots, y_n$ and the weights $d_{i1}, \dots, d_{in}$, gives

$$\phi(x_i) = \phi\Big(\sum_j d_{ij} y_j\Big) \;\le\; \sum_{j=1}^{n} d_{ij}\, \phi(y_j).$$

Summing over i and exchanging the order of the two finite sums,

$$\sum_{i=1}^{n} \phi(x_i) \;\le\; \sum_{j=1}^{n} \Big(\sum_{i=1}^{n} d_{ij}\Big) \phi(y_j) = \sum_{j=1}^{n} \phi(y_j),$$

because every column of $\mathbf{D}$ adds up to 1. This proves the theorem.

■

The proof is three lines and uses Theorem 20.1.3 once. That is what §01 was for: without it we would be comparing sorted partial sums with the values of an arbitrary convex function, and there is no route from one to the other.

Example. (One majorization, four inequalities)

Let $\mathbf{y} = (5, 3, 1, 1)$ and $\mathbf{x} = (3, 3, 2, 2)$. Check that $\mathbf{x} \prec \mathbf{y}$, and write down what Theorem 20.2.1 gives for $\phi(t) = t^2$, for $\phi(t) = |t - 2|$, and for $\phi(t) = \max\{t - 2, 0\}$.

Solution. Both vectors are decreasing with total 10, and the running totals are $3, 6, 8$ for $\mathbf{x}$ against $5, 8, 9$ for $\mathbf{y}$. So (M1) and (M2) hold, and $\mathbf{x} \prec \mathbf{y}$.

All three functions are convex on $I = \mathbb{R}$: t^2 by Lemma 17.10.5, since its derivative $2t$ is increasing, and the other two as pointwise maxima of affine functions, by Proposition 17.10.3 ($|t - 2| = \max\{t - 2,\ 2 - t\}$). So:

$$\begin{aligned} \textstyle\sum_i x_i^2 = 9 + 9 + 4 + 4 = 26 \;&\le\; 25 + 9 + 1 + 1 = 36 = \textstyle\sum_i y_i^2, \\ \textstyle\sum_i |x_i - 2| = 1 + 1 + 0 + 0 = 2 \;&\le\; 3 + 1 + 1 + 1 = 6, \\ \textstyle\sum_i \max\{x_i - 2, 0\} = 1 + 1 = 2 \;&\le\; 3 + 1 = 4. \end{aligned}$$

Each is an instance of the one theorem. The last one measures how much of each vector sits above the level 2, and it is the test function the converse below is built from.

Quick check. Does Theorem 20.2.1 apply to $\phi(t) = t^3$ on $I = \mathbb{R}$? Test it on $\mathbf{x} = (0, 0, 0) \prec \mathbf{y} = (1, 1, -2)$.

Solution. No. On $\mathbb{R}$ the function t^3 is not convex: at $a = -2$, $b = 0$ and $t = \frac{1}{2}$ the midpoint value is $\phi(-1) = -1$, while the chord gives $\frac{1}{2}\phi(-2) + \frac{1}{2}\phi(0) = -4$, and $-1 > -4$. The conclusion of the theorem does fail here. Both vectors have total 0, and the running totals $0, 0$ of $\mathbf{x}$ are at most $1, 2$, so $\mathbf{x} \prec \mathbf{y}$. But $\sum_i x_i^3 = 0$ while $\sum_i y_i^3 = 1 + 1 - 8 = -6$, and $0 > -6$. On $I = (0, \infty)$, where t^3 **is** convex, since its derivative $3t^2$ is increasing there (Lemma 17.10.5), the theorem does apply, and no such failure is possible for vectors with strictly positive entries.

20.2.2 The converse, and the weak version

Karamata's inequality is not merely a consequence of majorization; it is equivalent to it. Two families of test functions do the work: the affine ones pin down the totals, and the "hockey sticks" $t \mapsto \max\{t - c, 0\}$ pin down the partial sums.

Proposition 20.2.2 — Convex Functions Detect Majorization

Let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$. If

$$\sum_{i=1}^{n} \phi(x_i) \;\le\; \sum_{i=1}^{n} \phi(y_i)$$

for **every** convex $\phi\colon \mathbb{R} \to \mathbb{R}$, then $\mathbf{x} \prec \mathbf{y}$.

Idea. Use $\phi(t) = t$ and $\phi(t) = -t$ to get the equal totals. For the k-th partial sum, use the function that is 0 below a level c and rises with slope 1 above it. Summed over a vector it always exceeds "top k sum minus kc", and it *equals* that when c is the k-th largest entry. Setting $c = y_k^{\downarrow}$ makes the right-hand side exact and the left-hand side an over-estimate, which is the direction we need.

Proof. Both $\phi(t) = t$ and $\phi(t) = -t$ are affine, hence convex by Example (First convex functions) (a). They give $\sum_i x_i \le \sum_i y_i$ and $-\sum_i x_i \le -\sum_i y_i$, so the totals are equal. This is (M2).

Fix k with $1 \le k \le n - 1$, put $c = y_k^{\downarrow}$, and let

$$\phi_c(t) = \max\{t - c,\; 0\},$$

the pointwise maximum of the two affine functions $t \mapsto t - c$ and $t \mapsto 0$, hence convex by Proposition 17.10.3. For any $\mathbf{z} \in \mathbb{R}^n$ the sum $\sum_i \phi_c(z_i)$ does not depend on the order of the entries, so it equals $\sum_i \phi_c(z_i^{\downarrow})$. Every term is ≥ 0, and each of the first k terms satisfies $\phi_c(z_i^{\downarrow}) \ge z_i^{\downarrow} - c$. Hence

$$\sum_{i=1}^{n} \phi_c(z_i) \;\ge\; \sum_{i=1}^{k} z_i^{\downarrow} - kc. \tag{$*$}$$

For $\mathbf{z} = \mathbf{y}$ and this particular c, $(*)$ is an equality: for $i \le k$ we have $y_i^{\downarrow} \ge y_k^{\downarrow} = c$, so

$\phi_c(y_i^{\downarrow}) = y_i^{\downarrow} - c$; and for $i > k$ we have $y_i^{\downarrow} \le c$, so $\phi_c(y_i^{\downarrow}) = 0$. Therefore

$$\sum_{i=1}^{k} x_i^{\downarrow} - kc \overset{(*)}{\le} \sum_{i=1}^{n} \phi_c(x_i) \le \sum_{i=1}^{n} \phi_c(y_i) = \sum_{i=1}^{k} y_i^{\downarrow} - kc,$$

the middle step being the hypothesis applied to ϕ_c. Canceling kc gives (M1) at k. As k was arbitrary, $\mathbf{x} \prec \mathbf{y}$.

■

Together with Theorem 20.2.1 this is an equivalence: **$\mathbf{x} \prec \mathbf{y}$ if and only if** $\sum_i \phi(x_i) \le \sum_i \phi(y_i)$ for every convex $\phi\colon \mathbb{R} \to \mathbb{R}$. So majorization is exactly the order that all convex functions agree on. The proof also shows how few test functions are needed: the two affine ones and the $n-1$ hockey sticks at the levels $y_1^{\downarrow}, \dots, y_{n-1}^{\downarrow}$.

Weak majorization has a matching statement, with the class of test functions cut down.

Proposition 20.2.3 — Karamata for Weak Majorization

Let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ with $\mathbf{x} \prec_w \mathbf{y}$, and let $\phi\colon \mathbb{R} \to \mathbb{R}$ be convex and **increasing**. Then

$$\sum_{i=1}^{n} \phi(x_i) \le \sum_{i=1}^{n} \phi(y_i).$$

Idea. The only thing wrong with $\mathbf{y}$ is that its total may be too big. Take the excess away from the **smallest** entry of $\mathbf{y}$. That keeps the vector sorted, leaves all the partial sums before the last one untouched, and produces a genuine majorization, to which Theorem 20.2.1 applies. Lowering an entry can only lower ϕ, which is where "increasing" is used.

Proof. Let $s = \sum_i y_i - \sum_i x_i$. Taking $k = n$ in (M1) for $\mathbf{x} \prec_w \mathbf{y}$ gives $s \ge 0$. Define $\mathbf{w} \in \mathbb{R}^n$ by

$$w_i = y_i^{\downarrow} \quad (i \le n-1), \qquad w_n = y_n^{\downarrow} - s.$$

Only the last entry has changed, and it has been lowered, so $\mathbf{w}$ is still decreasing and $\mathbf{w}^{\downarrow} = \mathbf{w}$. Its total is $\sum_i y_i - s = \sum_i x_i$, which is (M2) for $\mathbf{x} \prec \mathbf{w}$. For $k \le n-1$, $\sum_{i \le k} w_i = \sum_{i \le k} y_i^{\downarrow} \ge \sum_{i \le k} x_i^{\downarrow}$ by (M1) for $\mathbf{x} \prec_w \mathbf{y}$. So $\mathbf{x} \prec \mathbf{w}$.

By Theorem 20.2.1 with $I = \mathbb{R}$, $\sum_i \phi(x_i) \le \sum_i \phi(w_i)$. Since $w_i \le y_i^{\downarrow}$ for every i and ϕ is increasing, $\phi(w_i) \le \phi(y_i^{\downarrow})$, so

$$\sum_{i} \phi(w_i) \le \sum_{i} \phi(y_i^{\downarrow}) = \sum_{i} \phi(y_i).$$

Chaining the two inequalities proves the proposition.

■

Warning. **"Increasing" cannot be dropped from Proposition 20.2.3.** Take $\mathbf{x} = (0, 0)$ and $\mathbf{y} = (1, 0)$. The running totals $0, 0$ of $\mathbf{x}$ are at most $1, 1$, so $\mathbf{x} \prec_w \mathbf{y}$. The function $\phi(t) = -t$ is convex but decreasing, and $\sum_i \phi(x_i) = 0$ while $\sum_i \phi(y_i) = -1$.

A weak majorization allows $\mathbf{y}$ to carry more total than $\mathbf{x}$, and a decreasing ϕ punishes exactly that.

20.2.3 Schur-convex functions

Theorem 20.2.1 is a statement about one particular shape of function, $\mathbf{x} \mapsto \sum_i \phi(x_i)$. The property it establishes deserves a name of its own, because many functions have it that are not of that shape.

A function is Schur-convex when spreading a vector out can only increase it.

The domain needs a moment's thought. If G is to be compared at $\mathbf{x}$ and $\mathbf{y}$ whenever $\mathbf{x} \prec \mathbf{y}$, then the domain must contain $\mathbf{x}$ as soon as it contains $\mathbf{y}$. Call a set $A \subseteq \mathbb{R}^n$ **symmetric** if $\mathbf{P}_\sigma \mathbf{x} \in A$ for every $\mathbf{x} \in A$ and every $\sigma \in S_n$. A symmetric **convex** set has the property we need: if $\mathbf{y} \in A$ and $\mathbf{x} \prec \mathbf{y}$, then $\mathbf{x} \in \operatorname{conv}\{\mathbf{P}_\sigma \mathbf{y}\}$ by Corollary 20.1.4, every $\mathbf{P}_\sigma \mathbf{y}$ lies in A by symmetry, and a convex set contains the convex combinations of its points (Lemma 17.1.2), so $\mathbf{x} \in A$.

Definition 20.2.1 — Schur-Convex Function

Let $A \subseteq \mathbb{R}^n$ be **symmetric and convex**, and let $G\colon A \to \mathbb{R}$. Then G is **Schur-convex** if

$$\mathbf{x} \prec \mathbf{y} \quad \Longrightarrow \quad G(\mathbf{x}) \le G(\mathbf{y})$$

for **all** $\mathbf{x}, \mathbf{y} \in A$. It is **strictly Schur-convex** if the inequality is **strict** whenever $\mathbf{x}^{\downarrow} \neq \mathbf{y}^{\downarrow}$.

Definition 20.2.2 — Schur-Concave Function

With A as in Definition 20.2.1, a function $G\colon A \to \mathbb{R}$ is **Schur-concave** if $-G$ is Schur-convex, that is, if

$$\mathbf{x} \prec \mathbf{y} \quad \Longrightarrow \quad G(\mathbf{x}) \ge G(\mathbf{y})$$

for all $\mathbf{x}, \mathbf{y} \in A$; and **strictly Schur-concave** if $-G$ is strictly Schur-convex.

In words: a Schur-convex function is one that respects the majorization order, and a Schur-concave one reverses it. The two standing examples of A below are $\mathbb{R}^n$ itself and the open orthant $\{\mathbf{x} : x_i > 0 \text{ for every } i\}$, both symmetric and convex.

A Schur-convex function is automatically **symmetric**, meaning $G(\mathbf{P}_\sigma \mathbf{x}) = G(\mathbf{x})$ for every permutation. Indeed $\mathbf{x}$ and $\mathbf{P}_\sigma \mathbf{x}$ are rearrangements of each other, so each majorizes the other (Proposition 16.8.1 (a) and the remark after Definition 16.8.1), and two applications of the definition give $G(\mathbf{x}) \le G(\mathbf{P}_\sigma \mathbf{x}) \le G(\mathbf{x})$.

Example. (Four functions on $\mathbb{R}^n$)

Decide which of the following are Schur-convex, and which are Schur-concave, on $A = \mathbb{R}^n$.

(a) $G(\mathbf{x}) = \sum_i x_i^2$.

(b) $G(\mathbf{x}) = \max_i x_i$.
(c) $G(\mathbf{x}) = \sum_i x_i$.
(d) $G(\mathbf{x}) = \sum_i x_i^3$, for $n = 3$.

Solution.

(a) Schur-convex. $\phi(t) = t^2$ is convex on $\mathbb{R}$, as in Example (One majorization, four inequalities), so Theorem 20.2.1 gives $\sum_i x_i^2 \le \sum_i y_i^2$ whenever $\mathbf{x} \prec \mathbf{y}$.

(b) Schur-convex. $\max_i x_i = x_1^{\downarrow}$, and (M1) at $k = 1$ says exactly $x_1^{\downarrow} \le y_1^{\downarrow}$. No convexity is needed here; the definition of majorization already contains the statement.

(c) Both Schur-convex and Schur-concave, since (M2) makes it constant on each majorization class. This is the degenerate case, and it shows that the two notions are not exclusive.

(d) Neither, and one pair of comparisons settles both. The flat vector is majorized by every vector with the same total (Example (A chain, the two extremes, and size one) (b)), so

$$(0,0,0) \prec (2,-1,-1), \qquad (0,0,0) \prec (1,1,-2),$$

both totals being 0. Now $G(0,0,0) = 0$, while $G(2,-1,-1) = 8 - 1 - 1 = 6$ and $G(1,1,-2) = 1 + 1 - 8 = -6$. Schur-convexity applied to the second majorization would demand $0 \le -6$, and Schur-concavity applied to the first would demand $0 \ge 6$. Both fail.

Part (d) is the non-example by minimal change. The function $\sum_i \phi(x_i)$ with $\phi(t) = t^3$ differs from the Schur-convex $\sum_i \phi(x_i)$ with $\phi(t) = t^2$ only in the exponent, and t^3 fails the one clause that matters, convexity on the interval where the entries live.

The next theorem explains why so many natural functions turn out Schur-convex: convexity plus symmetry is enough, and there is no need to be of the form $\sum_i \phi(x_i)$.

Theorem 20.2.4 — A Symmetric Convex Function Is Schur-Convex

Let $A \subseteq \mathbb{R}^n$ be symmetric and convex, and let $G\colon A \to \mathbb{R}$ be **convex** and **symmetric**, that is, $G(\mathbf{P}_\sigma \mathbf{x}) = G(\mathbf{x})$ for every $\mathbf{x} \in A$ and every $\sigma \in S_n$. Then G is Schur-convex.

Idea. $\mathbf{x} \prec \mathbf{y}$ puts $\mathbf{x}$ inside the permutation polytope of $\mathbf{y}$, whose corners all carry the **same** value of G, by symmetry. A convex function on a convex combination is at most the corresponding combination of its values, and an average of copies of one number is that number.

Proof. Let $\mathbf{x}, \mathbf{y} \in A$ with $\mathbf{x} \prec \mathbf{y}$. By Corollary 20.1.4 and Theorem 17.1.3,

$$\mathbf{x} = \sum_{i=1}^{m} t_i \, \mathbf{P}_{\sigma_i} \mathbf{y}$$

for some $\sigma_1, \dots, \sigma_m \in S_n$ and weights $t_i \ge 0$ with $\sum_i t_i = 1$. Each $\mathbf{P}_{\sigma_i}\mathbf{y}$ lies in A, since

A is symmetric. By Theorem 17.10.2 applied to the convex G on A,

$$G(\mathbf{x}) \;\le\; \sum_{i=1}^{m} t_i\, G(\mathbf{P}_{\sigma_i}\mathbf{y}) = \sum_{i=1}^{m} t_i\, G(\mathbf{y}) = G(\mathbf{y}),$$

the middle equality being the symmetry of G and the last one $\sum_i t_i = 1$. This shows that G is Schur-convex.

■

Now the promise from Chapter 16 §08. There the second proof of Hadamard's inequality used only the trace, and a remark recorded that a proof "by majorization in earnest" would need the fact that "for vectors with non-negative entries, $\mathbf{x} \prec \mathbf{y}$ implies $x_1 \cdots x_n \ge y_1 \cdots y_n$ (the product is **Schur-concave**)". Here it is.

Corollary 20.2.5 — The Product Is Schur-Concave

Let $\mathbf{y} \in \mathbb{R}^n$ have **non-negative** entries and let $\mathbf{x} \prec \mathbf{y}$. Then every entry of $\mathbf{x}$ is non-negative, and

$$x_1 x_2 \cdots x_n \;\ge\; y_1 y_2 \cdots y_n.$$

Idea. Take $-\log$, which is convex, and apply Theorem 20.2.1: the product becomes a sum and the inequality flips. The logarithm needs positive entries, so the case of a zero entry is dealt with first — and it is the easy case, because a zero entry makes the right-hand side 0 while the left-hand side is a product of non-negative numbers.

Proof. First, every entry of $\mathbf{x}$ is non-negative. For $n = 1$, (M2) gives $\mathbf{x} = \mathbf{y}$. For $n \ge 2$, subtracting (M1) at $k = n - 1$ from (M2) gives

$$x_n^{\downarrow} \;\ge\; y_n^{\downarrow} \;\ge\; 0,$$

and $x_n^{\downarrow}$ is the smallest entry of $\mathbf{x}$.

Case 1: some $y_i = 0$. Then $y_1 \cdots y_n = 0$, while $x_1 \cdots x_n \ge 0$ as a product of non-negative numbers. The inequality holds.

Case 2: every $y_i > 0$. Then $y_n^{\downarrow} > 0$, so $x_n^{\downarrow} > 0$ by the display above, and every entry of both vectors lies in $I = (0, \infty)$. By Lemma 17.11.1 (c) the function $\log$ is concave on I, so $\phi = -\log$ is convex there. By Theorem 20.2.1,

$$\sum_{i=1}^{n} \bigl(-\log x_i\bigr) \;\le\; \sum_{i=1}^{n} \bigl(-\log y_i\bigr), \qquad \text{that is,} \qquad \sum_{i=1}^{n} \log y_i \;\le\; \sum_{i=1}^{n} \log x_i.$$

By $\log(ab) = \log a + \log b$ (Lemma 17.11.1 (c)) and induction on n, $\sum_i \log x_i = \log(x_1 \cdots x_n)$ and likewise for $\mathbf{y}$. So $\log(y_1 \cdots y_n) \le \log(x_1 \cdots x_n)$. Since $\log$ is strictly increasing on I (Lemma 17.11.1 (c)), two positive numbers with $\log u \le \log v$ satisfy $u \le v$; otherwise $u > v$ would give $\log u > \log v$. Hence $y_1 \cdots y_n \le x_1 \cdots x_n$. This proves the corollary.

■

So the flat vector, the bottom of the majorization order, has the largest product among non-

negative vectors with a fixed total — which is Lemma 16.8.6 again, now as a special case rather than a separate induction.

Warning. **Schur-convex does not mean convex.** By Corollary 20.2.5 the function $G(\mathbf{x}) = -x_1x_2$ is Schur-convex on the symmetric convex set $A = \{\mathbf{x} \in \mathbb{R}^2 : x_1, x_2 \geq 0\}$. It is not convex: at $\mathbf{x} = (1,1)$, $\mathbf{y} = (2,2)$ and $t = \frac{1}{2}$,

$$G\left(\tfrac{3}{2}, \tfrac{3}{2}\right) = -\tfrac{9}{4} = -2.25, \qquad \tfrac{1}{2}G(1,1) + \tfrac{1}{2}G(2,2) = \tfrac{1}{2}(-1) + \tfrac{1}{2}(-4) = -2.5,$$

and $-2.25 > -2.5$. Theorem 20.2.4 is a one-way street.

Quick check. Is the function $G(\mathbf{x}) = x_1^{\downarrow} + x_2^{\downarrow}$ on $\mathbb{R}^3$ Schur-convex? Is it convex?

Solution. Schur-convex: the inequality $x_1^{\downarrow} + x_2^{\downarrow} \leq y_1^{\downarrow} + y_2^{\downarrow}$ is (M1) at $k = 2$. Convex: yes, and this gives a second proof. The two largest entries have the largest sum among all pairs, so $G(\mathbf{x}) = \max_{i<j}(x_i + x_j)$, a maximum of three linear functions, convex by Proposition 17.10.3. It is also symmetric, so Theorem 20.2.4 applies. (This G is the Ky Fan sum s_2 of Chapter 16 §06, read on vectors instead of eigenvalues.)

20.2.4 Convex functions of a Hermitian matrix

The last payoff is about matrices. For a Hermitian $\mathbf{A}$ and a convex f on an interval containing $\operatorname{spec}(\mathbf{A})$, the number $\operatorname{tr} f(\mathbf{A})$ turns out to be $\sum_i f(\lambda_i(\mathbf{A}))$. Chapter 17 §10 stated, and deferred, that this is a convex function of $\mathbf{A}$. The proof needs two lemmas: a bookkeeping one about traces, and one saying that the quadratic form of $f(\mathbf{A})$ dominates f of the quadratic form of $\mathbf{A}$.

Lemma 20.2.6 — Reading a Trace on an Orthonormal Basis

Let $F = \mathbb{R}$ or $\mathbb{C}$.

(a) Let $(\mathbf{u}_1, \dots, \mathbf{u}_n)$ be an orthonormal basis of F^n and $\mathbf{M} \in M_n(F)$. Then $\operatorname{tr}\mathbf{M} = \sum_{i=1}^n \langle \mathbf{M}\mathbf{u}_i, \mathbf{u}_i \rangle$.

(b) Let $I \subseteq \mathbb{R}$, let $\mathbf{A} \in M_n(F)$ be Hermitian with $\operatorname{spec}(\mathbf{A}) \subseteq I$, and let $g\colon I \to \mathbb{R}$. Then $g(\mathbf{A})\mathbf{u} = g(\lambda)\mathbf{u}$ for every eigenvector $\mathbf{u}$ of $\mathbf{A}$ with eigenvalue λ, and $\operatorname{tr} g(\mathbf{A}) = \sum_{i=1}^n g\big(\lambda_i(\mathbf{A})\big)$.

Proof.

(a) Let $\mathbf{U} \in M_n(F)$ be the matrix whose i-th column is $\mathbf{u}_i$. Then $(\mathbf{U}^*\mathbf{U})_{ij} = \mathbf{u}_i^*\mathbf{u}_j = \langle \mathbf{u}_j, \mathbf{u}_i \rangle = \delta_{ij}$, so $\mathbf{U}$ is unitary, and $(\mathbf{U}^*\mathbf{M}\mathbf{U})_{ii} = \mathbf{u}_i^*\mathbf{M}\mathbf{u}_i = \langle \mathbf{M}\mathbf{u}_i, \mathbf{u}_i \rangle$. By Theorem 0.9.6 (3), used with the factors $\mathbf{U}^*$ and $\mathbf{M}\mathbf{U}$, $\operatorname{tr}(\mathbf{U}^*\mathbf{M}\mathbf{U}) = \operatorname{tr}(\mathbf{M}\mathbf{U}\mathbf{U}^*) = \operatorname{tr}\mathbf{M}$. Summing the diagonal of $\mathbf{U}^*\mathbf{M}\mathbf{U}$ gives (a).

(b) Let $\mathbf{A} = \sum_j \mu_j \mathbf{P}_j$ be the spectral resolution of Definition 11.8.1, with $\mu_1, \dots, \mu_k$ the distinct eigenvalues; it exists by Theorem 11.8.1, since a Hermitian matrix has an orthonormal basis of eigenvectors (Corollary 11.4.3 over $\mathbb{C}$, Corollary 11.5.2 over $\mathbb{R}$). Let $\mathbf{A}\mathbf{u} = \lambda\mathbf{u}$ with $\mathbf{u} \neq \mathbf{0}$. Then $\lambda = \mu_{j_0}$ for exactly one j_0, and $\mathbf{u}$ lies in the eigenspace of μ_{j_0}, which is the image of $\mathbf{P}_{j_0}$; so $\mathbf{P}_{j_0}\mathbf{u} = \mathbf{u}$, and $\mathbf{P}_j\mathbf{u} = \mathbf{P}_j\mathbf{P}_{j_0}\mathbf{u} = \mathbf{0}$ for $j \neq j_0$ by Theorem 11.8.1 (b). Hence $g(\mathbf{A})\mathbf{u} = \sum_j g(\mu_j)\mathbf{P}_j\mathbf{u} = g(\lambda)\mathbf{u}$, by Definition 11.8.2.

Now take an orthonormal basis $(\mathbf{u}_1, \dots, \mathbf{u}_n)$ of F^n with $\mathbf{A}\mathbf{u}_i = \lambda_i(\mathbf{A})\mathbf{u}_i$, which exists by the spectral theorem just cited. By the previous paragraph, $\langle g(\mathbf{A})\mathbf{u}_i, \mathbf{u}_i\rangle = g(\lambda_i(\mathbf{A}))\langle \mathbf{u}_i, \mathbf{u}_i\rangle = g(\lambda_i(\mathbf{A}))$, and (a) adds these up to $\operatorname{tr} g(\mathbf{A})$.

■

Lemma 20.2.7 — Peierls' Inequality

Let $I \subseteq \mathbb{R}$ be an interval, let $\mathbf{A} \in M_n(F)$ be Hermitian with $\operatorname{spec}(\mathbf{A}) \subseteq I$, let $f\colon I \to \mathbb{R}$ be convex, and let $\mathbf{u} \in F^n$ with $\|\mathbf{u}\| = 1$. Then $\langle \mathbf{A}\mathbf{u}, \mathbf{u}\rangle \in I$ and

$$f\big(\langle \mathbf{A}\mathbf{u}, \mathbf{u}\rangle\big) \;\le\; \langle f(\mathbf{A})\mathbf{u}, \mathbf{u}\rangle,$$

with **equality** when $\mathbf{u}$ is an eigenvector of $\mathbf{A}$.

Idea. Write $\mathbf{A} = \sum_j \mu_j \mathbf{P}_j$, its spectral resolution. Then $\langle \mathbf{A}\mathbf{u}, \mathbf{u}\rangle = \sum_j \mu_j \|\mathbf{P}_j\mathbf{u}\|^2$ is a weighted average of the eigenvalues, with weights $\|\mathbf{P}_j\mathbf{u}\|^2$ that add up to $\|\mathbf{u}\|^2 = 1$. The same weights appear in $\langle f(\mathbf{A})\mathbf{u}, \mathbf{u}\rangle = \sum_j f(\mu_j)\|\mathbf{P}_j\mathbf{u}\|^2$. So the two sides of the inequality are f of an average against the average of f, which is Jensen.

Proof. Let $\mathbf{A} = \mu_1\mathbf{P}_1 + \cdots + \mu_k\mathbf{P}_k$ be the spectral resolution of Definition 11.8.1, with $\mu_1, \dots, \mu_k$ the **distinct** eigenvalues of $\mathbf{A}$, which exists by Theorem 11.8.1 since a Hermitian matrix has an orthonormal basis of eigenvectors (Corollary 11.4.3 over $\mathbb{C}$, Corollary 11.5.2 over $\mathbb{R}$). Put

$$w_j = \langle \mathbf{P}_j\mathbf{u}, \mathbf{u}\rangle.$$

By Theorem 11.8.1 (b), $\mathbf{P}_j = \mathbf{P}_j^2$ and $\mathbf{P}_j^* = \mathbf{P}_j$, so

$$w_j = \langle \mathbf{P}_j\mathbf{P}_j\mathbf{u}, \mathbf{u}\rangle = \langle \mathbf{P}_j\mathbf{u}, \mathbf{P}_j^*\mathbf{u}\rangle = \langle \mathbf{P}_j\mathbf{u}, \mathbf{P}_j\mathbf{u}\rangle = \|\mathbf{P}_j\mathbf{u}\|^2 \;\ge\; 0,$$

and by Theorem 11.8.1 (c), $\sum_j w_j = \langle \mathbf{u}, \mathbf{u}\rangle = 1$. Hence, by Theorem 11.8.1 (d) and Definition 11.8.2,

$$\langle \mathbf{A}\mathbf{u}, \mathbf{u}\rangle = \sum_{j=1}^{k} \mu_j w_j, \qquad \langle f(\mathbf{A})\mathbf{u}, \mathbf{u}\rangle = \sum_{j=1}^{k} f(\mu_j) w_j.$$

The first is a convex combination of $\mu_1, \dots, \mu_k$, all of which lie in the convex set I, so $\langle \mathbf{A}\mathbf{u}, \mathbf{u}\rangle \in I$ by Lemma 17.1.2. Applying Theorem 17.10.2 to the convex f on I, with points μ_j and weights w_j,

$$f\big(\langle \mathbf{A}\mathbf{u}, \mathbf{u}\rangle\big) = f\Big(\sum_j w_j\mu_j\Big) \;\le\; \sum_j w_j f(\mu_j) = \langle f(\mathbf{A})\mathbf{u}, \mathbf{u}\rangle.$$

For the equality clause, let $\mathbf{A}\mathbf{u} = \lambda\mathbf{u}$ with $\|\mathbf{u}\| = 1$. By Lemma 20.2.6 (b), $f(\mathbf{A})\mathbf{u} = f(\lambda)\mathbf{u}$, so the right side is $f(\lambda)\langle \mathbf{u}, \mathbf{u}\rangle = f(\lambda)$; and the left side is $f(\langle \lambda\mathbf{u}, \mathbf{u}\rangle) = f(\lambda)$ as well. This proves the lemma.

■

Quick check. Take $\mathbf{A} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$, $f(t) = t^2$ and $\mathbf{u} = \mathbf{e}_1$. Compute both sides of Lemma 20.2.7, and then repeat with $\mathbf{u} = \frac{1}{\sqrt{2}}(1, 1)$.

Solution. $\langle \mathbf{A}\mathbf{e}_1, \mathbf{e}_1 \rangle = a_{11} = 2$, so the left side is $f(2) = 4$. Here $f(\mathbf{A}) = \mathbf{A}^2 = \left(\begin{smallmatrix} 5 & 4 \\ 4 & 5 \end{smallmatrix}\right)$, so the right side is $(\mathbf{A}^2)_{11} = 5$. Indeed $4 \leq 5$, and the inequality is strict because $\mathbf{e}_1$ is not an eigenvector of $\mathbf{A}$.

For $\mathbf{u} = \frac{1}{\sqrt{2}}(1, 1)$, an eigenvector with $\mathbf{A}\mathbf{u} = 3\mathbf{u}$, the left side is $f(3) = 9$ and the right side is $\langle \mathbf{A}^2\mathbf{u}, \mathbf{u} \rangle = 9\langle \mathbf{u}, \mathbf{u} \rangle = 9$. Equality, as the lemma says.

Theorem 20.2.8 — The Trace of a Convex Function Is Convex

Let $I \subseteq \mathbb{R}$ be an interval and let $f \colon I \to \mathbb{R}$ be **convex**. Let $\mathbf{A}, \mathbf{B} \in M_n(F)$ be Hermitian with $\operatorname{spec}(\mathbf{A}) \subseteq I$ and $\operatorname{spec}(\mathbf{B}) \subseteq I$, and let $0 \leq \theta \leq 1$. Then $\mathbf{C} = \theta\mathbf{A} + (1 - \theta)\mathbf{B}$ is Hermitian with $\operatorname{spec}(\mathbf{C}) \subseteq I$, and

$$\operatorname{tr} f(\mathbf{C}) \;\leq\; \theta \operatorname{tr} f(\mathbf{A}) + (1 - \theta) \operatorname{tr} f(\mathbf{B}).$$

In words: the Hermitian matrices with spectrum in I form a **convex** set, and $\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A})$ is a **convex** function on it.

Idea. Fix an orthonormal eigenbasis of the midpoint matrix $\mathbf{C} = \theta\mathbf{A} + (1 - \theta)\mathbf{B}$. Along each of those n directions the value of f at the eigenvalue of $\mathbf{C}$ is exactly the left side of Peierls' inequality, because an eigenvector gives equality; and the eigenvalue itself splits as θ times a quadratic form of $\mathbf{A}$ plus $(1 - \theta)$ times one of $\mathbf{B}$. Ordinary convexity of f handles that split, and Peierls' inequality, now as an inequality, converts the two quadratic forms into quadratic forms of $f(\mathbf{A})$ and $f(\mathbf{B})$. Summing over the basis turns quadratic forms into traces.

Proof. **Step 1: the spectrum of C.** The matrix $\mathbf{C} = \theta\mathbf{A} + (1 - \theta)\mathbf{B}$ is Hermitian, being a real combination of Hermitian matrices. Let μ be an eigenvalue of $\mathbf{C}$, with unit eigenvector $\mathbf{x}$. Then

$$\mu = \langle \mathbf{C}\mathbf{x}, \mathbf{x} \rangle = \theta\langle \mathbf{A}\mathbf{x}, \mathbf{x} \rangle + (1 - \theta)\langle \mathbf{B}\mathbf{x}, \mathbf{x} \rangle.$$

By Lemma 12.5.2, $\langle \mathbf{A}\mathbf{x}, \mathbf{x} \rangle$ lies in $[\lambda_n(\mathbf{A}), \lambda_1(\mathbf{A})]$, an interval whose endpoints are eigenvalues of $\mathbf{A}$, hence contained in I; likewise $\langle \mathbf{B}\mathbf{x}, \mathbf{x} \rangle \in I$. So μ is a convex combination of two points of I and lies in I. Hence $\operatorname{spec}(\mathbf{C}) \subseteq I$, and $f(\mathbf{C})$ is defined.

Step 2: the inequality. Choose an orthonormal basis $(\mathbf{u}_1, \ldots, \mathbf{u}_n)$ of F^n consisting of eigenvectors of $\mathbf{C}$, which exists by Corollary 11.4.3 over $\mathbb{C}$ and Corollary 11.5.2 over $\mathbb{R}$. Fix i. By Lemma 20.2.7 applied to $\mathbf{C}$ and the eigenvector $\mathbf{u}_i$, with equality,

$$\langle f(\mathbf{C})\mathbf{u}_i, \mathbf{u}_i \rangle = f\big(\langle \mathbf{C}\mathbf{u}_i, \mathbf{u}_i \rangle\big).$$

By Step 1, $\langle \mathbf{C}\mathbf{u}_i, \mathbf{u}_i \rangle = \theta\alpha_i + (1 - \theta)\beta_i$ with $\alpha_i = \langle \mathbf{A}\mathbf{u}_i, \mathbf{u}_i \rangle \in I$ and $\beta_i = \langle \mathbf{B}\mathbf{u}_i, \mathbf{u}_i \rangle \in I$. So Definition 17.10.1 and then Lemma 20.2.7, now applied to $\mathbf{A}$ and to $\mathbf{B}$ with the unit vector $\mathbf{u}_i$, give

$$\begin{aligned} \langle f(\mathbf{C})\mathbf{u}_i, \mathbf{u}_i \rangle = f\big(\theta\alpha_i + (1 - \theta)\beta_i\big) &\leq \theta f(\alpha_i) + (1 - \theta) f(\beta_i) \\ &\leq \theta\langle f(\mathbf{A})\mathbf{u}_i, \mathbf{u}_i \rangle + (1 - \theta)\langle f(\mathbf{B})\mathbf{u}_i, \mathbf{u}_i \rangle, \end{aligned}$$

where the last step uses $\theta \geq 0$ and $1-\theta \geq 0$. Summing over $i = 1, \dots, n$ and using Lemma 20.2.6 (a) three times, once for each of $f(\mathbf{C})$, $f(\mathbf{A})$ and $f(\mathbf{B})$,

$$\operatorname{tr} f(\mathbf{C}) \;\leq\; \theta \operatorname{tr} f(\mathbf{A}) + (1-\theta) \operatorname{tr} f(\mathbf{B}).$$

Since $\mathbf{A}$, $\mathbf{B}$ and θ were arbitrary, this is Definition 17.10.1 for $\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A})$ on the set of Hermitian matrices with spectrum in I, which Step 1 shows is convex. This proves the theorem.

■

This pays Chapter 17 §10's "it is proved in Chapter 20, and nothing in this chapter uses it", and Chapter 17 §11's closing note that "the convexity of $\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A})$ for convex f, and the consequences of a majorization for every convex function, belong to Chapter 20".

Example. (The logarithm of the determinant)

Let $f(t) = -\log t$ on $I = (0, \infty)$, so that the matrices in play are the positive definite Hermitian ones. Identify $\operatorname{tr} f(\mathbf{A})$, and check the resulting inequality for

$$\mathbf{A} = \begin{pmatrix} 1 & 0 \\ 0 & 4 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}, \qquad \theta = \tfrac{1}{2}.$$

Solution. A Hermitian $\mathbf{A}$ has $\operatorname{spec}(\mathbf{A}) \subseteq (0, \infty)$ exactly when $\mathbf{A} \succ 0$, by Theorem 12.1.5 (b). For such an $\mathbf{A}$, Lemma 20.2.6 (b), then $\log(ab) = \log a + \log b$ (Lemma 17.11.1 (c)) with induction on n, and then Theorem 8.3.3 give

$$\operatorname{tr} f(\mathbf{A}) = -\sum_i \log \lambda_i(\mathbf{A}) = -\log \prod_i \lambda_i(\mathbf{A}) = -\log\det \mathbf{A}.$$

By Theorem 20.2.8, $\mathbf{A} \mapsto -\log\det \mathbf{A}$ **is convex on the positive definite matrices**; equivalently, det is log-concave there.

For the data given, $\det \mathbf{A} = 4$ and $\det \mathbf{B} = 4 - 1 = 3$, and

$$\mathbf{C} = \tfrac{1}{2}(\mathbf{A} + \mathbf{B}) = \begin{pmatrix} \frac{3}{2} & \frac{1}{2} \\ \frac{1}{2} & 3 \end{pmatrix}, \qquad \det \mathbf{C} = \tfrac{9}{2} - \tfrac{1}{4} = \tfrac{17}{4}.$$

Both $\mathbf{A}$ and $\mathbf{B}$ are positive definite ($\mathbf{A}$ is diagonal with positive entries; $\mathbf{B}$ has eigenvalues 3 and 1), so the theorem says $-\log \frac{17}{4} \leq -\frac{1}{2}\log 4 - \frac{1}{2}\log 3$, that is, after multiplying by -1 and exponentiating,

$$\det \mathbf{C} = \tfrac{17}{4} = 4.25 \;\geq\; \sqrt{4 \cdot 3} = \sqrt{12} \approx 3.464,$$

which holds, since $4.25^2 = 18.0625 \geq 12$.

Remark. Theorem 20.2.8 holds for **every** convex f, which is a very large class. It is nonetheless much weaker than the operator convexity of Definition 16.11.1 (b), which asks for $f(\theta\mathbf{A} + (1-\theta)\mathbf{B}) \preceq \theta f(\mathbf{A}) + (1-\theta) f(\mathbf{B})$ in the Loewner order, a statement about matrices rather than about one number extracted from them. Taking traces turns the Loewner inequality into the one proved here, since the trace of a positive semidefinite matrix is the sum of its non-negative eigenvalues (Theorem 12.1.4 (b), Theorem 8.3.3); so operator convexity implies trace convexity, but the converse fails badly, and a later

section of this chapter exhibits convex functions that are not operator convex.

20.2.5 Exercises

20.2.5.1 A. Check your understanding

Exercise A1.

(a) State Karamata's inequality, with all its hypotheses.

(b) Which test functions prove Proposition 20.2.2, and which clause of Definition 16.8.1 does each one give?

(c) Define Schur-convex and Schur-concave.

(d) True or false: every Schur-convex function on $\mathbb{R}^n$ is convex. Justify your answer.

(e) True or false: every convex function on $\mathbb{R}^n$ is Schur-convex. Justify your answer.

(f) State what Theorem 20.2.8 says for $f(t) = t^2$, and identify the resulting function of $\mathbf{A}$.

Solution.

(a) If I is an interval, $\phi\colon I \to \mathbb{R}$ is convex, $\mathbf{x} \prec \mathbf{y}$ in $\mathbb{R}^n$, and every entry of $\mathbf{y}$ lies in I, then every entry of $\mathbf{x}$ lies in I and $\sum_i \phi(x_i) \le \sum_i \phi(y_i)$ (Theorem 20.2.1).

(b) The affine functions $\phi(t) = t$ and $\phi(t) = -t$ give the equal totals, (M2). The hockey stick $\phi_c(t) = \max\{t - c, 0\}$ with $c = y_k^{\downarrow}$ gives (M1) at k.

(c) For a symmetric convex $A \subseteq \mathbb{R}^n$, $G\colon A \to \mathbb{R}$ is Schur-convex if $\mathbf{x} \prec \mathbf{y}$ implies $G(\mathbf{x}) \le G(\mathbf{y})$ (Definition 20.2.1), and Schur-concave if $\mathbf{x} \prec \mathbf{y}$ implies $G(\mathbf{x}) \ge G(\mathbf{y})$ (Definition 20.2.2).

(d) False. $G(\mathbf{x}) = -x_1 x_2$ on the non-negative quadrant is Schur-convex by Corollary 20.2.5, but the warning after that corollary shows that $G(\frac{3}{2}, \frac{3}{2}) = -2.25$ exceeds the average -2.5 of $G(1,1)$ and $G(2,2)$.

(e) False. A Schur-convex function must be symmetric, as shown after Definition 20.2.2, and $G(\mathbf{x}) = x_1$ is linear, hence convex, but not symmetric: $G(1,0) = 1 \neq 0 = G(0,1)$, while $(1,0)$ and $(0,1)$ majorize each other. Symmetry is exactly the missing hypothesis of Theorem 20.2.4.

(f) For $I = \mathbb{R}$ and $f(t) = t^2$, it says that $\mathbf{A} \mapsto \operatorname{tr}(\mathbf{A}^2)$ is convex on the Hermitian matrices. Since $\mathbf{A}$ is Hermitian, $\operatorname{tr}(\mathbf{A}^2) = \operatorname{tr}(\mathbf{A}^*\mathbf{A}) = \|\mathbf{A}\|_F^2$, the squared Frobenius norm.

20.2.5.2 B. Practice

Exercise B1: Four consequences of one majorization.

Let $\mathbf{y} = (6, 2, 1, 1)$ and $\mathbf{x} = (4, 3, 2, 1)$.

(a) Verify that $\mathbf{x} \prec \mathbf{y}$.

(b) Compute $\sum_i x_i^2$ and $\sum_i y_i^2$, and $\sum_i \max\{x_i - 3, 0\}$ and $\sum_i \max\{y_i - 3, 0\}$. Name the theorem each comparison illustrates.

(c) Compute $\prod_i x_i$ and $\prod_i y_i$. Hence check Corollary 20.2.5.

(d) Give a convex $\phi\colon \mathbb{R} \to \mathbb{R}$ for which the two sides are **equal**.

Solution.

(a) Both vectors are decreasing with total 10; the running totals are $4, 7, 9$ for $\mathbf{x}$ against $6, 8, 9$ for $\mathbf{y}$. So (M1) and (M2) hold.

(b) $\sum_i x_i^2 = 16 + 9 + 4 + 1 = 30$ and $\sum_i y_i^2 = 36 + 4 + 1 + 1 = 42$, so $30 \le 42$. Also $\sum_i \max\{x_i - 3, 0\} = 1 + 0 + 0 + 0 = 1$ and $\sum_i \max\{y_i - 3, 0\} = 3$, so $1 \le 3$. Both illustrate Theorem 20.2.1, the first with $\phi(t) = t^2$ and the second with the hockey stick at level 3.

(c) $\prod_i x_i = 4 \cdot 3 \cdot 2 \cdot 1 = 24$ and $\prod_i y_i = 6 \cdot 2 \cdot 1 \cdot 1 = 12$. Indeed $24 \ge 12$, as Corollary 20.2.5 requires for non-negative vectors.

(d) Any affine ϕ, for instance $\phi(t) = t$: both sides are the common total 10, by (M2). Affine functions are the ones on which majorization gives no information.

Exercise B2: Which are Schur-convex?.

Determine which of the following functions are Schur-convex on the stated symmetric convex set. Justify your answer, naming the theorem used or giving a counterexample.

(a) $G(\mathbf{x}) = \max_i x_i - \min_i x_i$ on $\mathbb{R}^n$.

(b) $G(\mathbf{x}) = \sum_i |x_i|$ on $\mathbb{R}^n$.

(c) $G(\mathbf{x}) = x_1 + 2x_2$ on $\mathbb{R}^2$.

(d) $G(\mathbf{x}) = \sum_i \sqrt{x_i}$ on $A = \{\mathbf{x} \in \mathbb{R}^n : x_i > 0 \text{ for every } i\}$.

Solution.

(a) Schur-convex. $G(\mathbf{x}) = x_1^{\downarrow} - x_n^{\downarrow}$, and $\mathbf{x} \prec \mathbf{y}$ gives $x_1^{\downarrow} \le y_1^{\downarrow}$ by (M1) at $k = 1$ and $x_n^{\downarrow} \ge y_n^{\downarrow}$ by subtracting (M1) at $k = n-1$ from (M2). Subtracting the second from the first gives $G(\mathbf{x}) \le G(\mathbf{y})$.

(b) Schur-convex, by Theorem 20.2.1 with $\phi(t) = |t|$, convex as a maximum of two affine functions (Proposition 17.10.3).

(c) Not Schur-convex. It is not symmetric, and a Schur-convex function must be. Concretely $(1, 0)$ and $(0, 1)$ are rearrangements of each other, so $(1, 0) \prec (0, 1)$ and $(0, 1) \prec (1, 0)$. Schur-convexity would give $G(1, 0) \le G(0, 1)$ from the first and $G(0, 1) \le G(1, 0)$ from the second, hence $G(1, 0) = G(0, 1)$. But $G(1, 0) = 1$ and $G(0, 1) = 2$.

(d) Not Schur-convex; it is Schur-**concave**. First, $t \mapsto \sqrt{t}$ is concave on $(0, \infty)$: for $a, b > 0$ and $0 \le \theta \le 1$, Lemma 16.8.6 gives $2\sqrt{ab} \le a + b$, so

$$\begin{aligned}\left(\theta\sqrt{a} + (1-\theta)\sqrt{b}\right)^2 &= \theta^2 a + (1-\theta)^2 b + 2\theta(1-\theta)\sqrt{ab} \\ &\le \theta^2 a + (1-\theta)^2 b + \theta(1-\theta)(a+b) \\ &= \theta a + (1-\theta) b,\end{aligned}$$

using $\theta^2 + \theta(1-\theta) = \theta$ and $(1-\theta)^2 + \theta(1-\theta) = 1 - \theta$; taking square roots of two non-negative numbers preserves the inequality. So $\phi(t) = -\sqrt{t}$ is convex on $(0, \infty)$, and Theorem 20.2.1 turns $\mathbf{x} \prec \mathbf{y}$ into $\sum_i(-\sqrt{x_i}) \le \sum_i(-\sqrt{y_i})$, that is,

$G(\mathbf{x}) \geq G(\mathbf{y})$. For a concrete instance, $(2,2) \prec (3,1)$ and $G(2,2) = 2\sqrt{2} \approx 2.83$, while $G(3,1) = \sqrt{3}+1 \approx 2.73$, so G went **down** as the vector spread out.

Exercise B3: Trace convexity on two-by-two matrices.

(a) Let $f(t) = t^2$, $\mathbf{A} = \operatorname{diag}(2,0)$, $\mathbf{B} = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ and $\theta = \frac{1}{2}$. Compute $\operatorname{tr} f(\mathbf{A})$, $\operatorname{tr} f(\mathbf{B})$ and $\operatorname{tr} f(\mathbf{C})$ for $\mathbf{C} = \frac{1}{2}(\mathbf{A}+\mathbf{B})$, and verify Theorem 20.2.8.

(b) Let $f(t) = -\log t$, $\mathbf{A} = \mathbf{I}_2$, $\mathbf{B} = \operatorname{diag}(4, \frac{1}{4})$ and $\theta = \frac{1}{2}$. Do the same, and state the inequality in terms of determinants.

Solution.

(a) Both matrices are real symmetric, hence Hermitian. $\mathbf{A}^2 = \operatorname{diag}(4,0)$, so $\operatorname{tr} f(\mathbf{A}) = 4$; and $\mathbf{B}^2 = \left(\begin{smallmatrix} 2 & 2 \\ 2 & 2 \end{smallmatrix}\right)$, so $\operatorname{tr} f(\mathbf{B}) = 4$. Next

$$\mathbf{C} = \tfrac{1}{2}\begin{pmatrix} 3 & 1 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} \frac{3}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix}, \qquad \mathbf{C}^2 = \begin{pmatrix} \frac{5}{2} & 1 \\ 1 & \frac{1}{2} \end{pmatrix},$$

so $\operatorname{tr} f(\mathbf{C}) = \frac{5}{2} + \frac{1}{2} = 3$. The theorem asserts $3 \leq \frac{1}{2}\cdot 4 + \frac{1}{2}\cdot 4 = 4$, which holds.

(b) Both are positive definite, so their spectra lie in $(0,\infty)$. By Example (The logarithm of the determinant), $\operatorname{tr} f(\mathbf{M}) = -\log\det \mathbf{M}$. Here $\det \mathbf{A} = 1$ and $\det \mathbf{B} = 4 \cdot \frac{1}{4} = 1$, so both traces are $-\log 1 = 0$. The midpoint is $\mathbf{C} = \operatorname{diag}(\frac{5}{2}, \frac{5}{8})$, with $\det \mathbf{C} = \frac{25}{16}$, so $\operatorname{tr} f(\mathbf{C}) = -\log \frac{25}{16}$. The theorem asserts

$$-\log \tfrac{25}{16} \;\leq\; \tfrac{1}{2}\cdot 0 + \tfrac{1}{2}\cdot 0 = 0,$$

which holds because $\frac{25}{16} > 1$ and log is increasing with $\log 1 = 0$ (Lemma 17.11.1 (c)). In determinant form: $\det \mathbf{C} = \frac{25}{16} \geq 1 = \sqrt{\det \mathbf{A}\,\det \mathbf{B}}$.

20.2.5.3 C. Going deeper

Exercise C1: Entropy.

For $\mathbf{x}$ in $A = \{\mathbf{x} \in \mathbb{R}^n : x_i > 0 \text{ for every } i\}$, let $H(\mathbf{x}) = -\sum_i x_i \log x_i$.

(a) Prove that $g(t) = t\log t$ is convex on $(0,\infty)$. *Hint: apply Theorem 17.10.2 to the concave* log*, with the points $1/a$, $1/b$ and cleverly chosen weights.*

(b) Deduce that H is Schur-concave on A.

(c) Deduce that $H(\mathbf{x}) \leq \log n$ for every $\mathbf{x} \in A$ with $\sum_i x_i = 1$, with equality when $\mathbf{x} = (\frac{1}{n}, \ldots, \frac{1}{n})$.

Solution.

(a) Let $a, b > 0$ and $0 \leq \theta \leq 1$, and put $c = \theta a + (1-\theta)b > 0$. Set

$$w_1 = \frac{\theta a}{c}, \qquad w_2 = \frac{(1-\theta)b}{c},$$

which are non-negative and satisfy $w_1 + w_2 = (\theta a + (1-\theta)b)/c = 1$. The function

$-\log$ is convex on $(0,\infty)$ by Lemma 17.11.1 (c), so Theorem 17.10.2 with the points $1/a$ and $1/b$ gives

$$-\log\Big(w_1\frac{1}{a}+w_2\frac{1}{b}\Big) \;\le\; -w_1\log\frac{1}{a}-w_2\log\frac{1}{b}.$$

Now $w_1/a+w_2/b=\theta/c+(1-\theta)/c=1/c$, and $\log(1/a)=-\log a$ since $\log a+\log(1/a)=\log 1=0$ (Lemma 17.11.1 (c)). So the display reads

$$\log c \;\le\; w_1\log a+w_2\log b=\frac{\theta a\log a+(1-\theta)b\log b}{c}.$$

Multiplying by $c>0$ gives $c\log c\le\theta a\log a+(1-\theta)b\log b$, which is Definition 17.10.1 for g.

(b) By (a) and Theorem 20.2.1 with $I=(0,\infty)$, $\mathbf{x}\prec\mathbf{y}$ in A implies $\sum_i x_i\log x_i\le\sum_i y_i\log y_i$, that is, $H(\mathbf{x})\ge H(\mathbf{y})$. By Definition 20.2.2, H is Schur-concave. (The set A is symmetric and convex, so Definition 20.2.2 applies.)

(c) Let $\mathbf{x}\in A$ with $\sum_i x_i=1$. Its mean is $\frac{1}{n}$, so the flat vector $\mathbf{f}=(\frac{1}{n},\dots,\frac{1}{n})$ satisfies $\mathbf{f}\prec\mathbf{x}$ by Example (A chain, the two extremes, and size one) (b), and $\mathbf{f}\in A$. By (b), $H(\mathbf{f})\ge H(\mathbf{x})$. Finally

$$H(\mathbf{f})=-\sum_{i=1}^{n}\tfrac{1}{n}\log\tfrac{1}{n}=-\log\tfrac{1}{n}=\log n,$$

using $\log\frac{1}{n}=-\log n$. So $H(\mathbf{x})\le\log n$, with equality at $\mathbf{x}=\mathbf{f}$.

Exercise C2: Three norms under majorization.

Let $\mathbf{x}\prec\mathbf{y}$ in $\mathbb{R}^n$. Prove that

$$\|\mathbf{x}\|_1\le\|\mathbf{y}\|_1,\qquad \|\mathbf{x}\|_2\le\|\mathbf{y}\|_2,\qquad \|\mathbf{x}\|_\infty\le\|\mathbf{y}\|_\infty.$$

Which of the three needs Theorem 20.2.1, and which follows from Definition 16.8.1 alone?

Solution. For $\|\cdot\|_1$, apply Theorem 20.2.1 with $\phi(t)=|t|$, convex on $\mathbb{R}$ by Proposition 17.10.3: $\sum_i|x_i|\le\sum_i|y_i|$.

For $\|\cdot\|_2$, apply Theorem 20.2.1 with $\phi(t)=t^2$, convex on $\mathbb{R}$ by Lemma 17.10.5, since its derivative $2t$ is increasing: $\sum_i x_i^2\le\sum_i y_i^2$. Both sides are non-negative and $t\mapsto\sqrt{t}$ is increasing on $[0,\infty)$, so $\|\mathbf{x}\|_2\le\|\mathbf{y}\|_2$.

For $\|\cdot\|_\infty$, no convexity is needed. Since $\|\mathbf{z}\|_\infty=\max_i|z_i|=\max\{z_1^{\downarrow},\,-z_n^{\downarrow}\}$, and (M1) at $k=1$ gives $x_1^{\downarrow}\le y_1^{\downarrow}$ while subtracting (M1) at $k=n-1$ from (M2) gives $x_n^{\downarrow}\ge y_n^{\downarrow}$, hence $-x_n^{\downarrow}\le -y_n^{\downarrow}$. The maximum of the two smaller numbers is at most the maximum of the two larger ones.

So the ∞-norm follows from Definition 16.8.1 directly, and the other two from Theorem 20.2.1. A later section of this chapter proves the same for **every** norm that is invariant under permuting and changing the signs of the coordinates.

Exercise C3: One convex function is not enough.

Let $\mathbf{x} = (2, -1, -1)$ and $\mathbf{y} = (1, 1, -2)$.

(a) Show that $\sum_i x_i = \sum_i y_i$ and $\sum_i x_i^2 = \sum_i y_i^2$, yet neither $\mathbf{x} \prec \mathbf{y}$ nor $\mathbf{y} \prec \mathbf{x}$.

(b) Exhibit a convex ϕ with $\sum_i \phi(x_i) > \sum_i \phi(y_i)$, and another with the inequality reversed. Explain how this is consistent with Proposition 20.2.2.

Solution.

(a) Both totals are 0, and $\sum_i x_i^2 = 4 + 1 + 1 = 6 = 1 + 1 + 4 = \sum_i y_i^2$. Both vectors are already decreasing, with running totals $2, 1$ for $\mathbf{x}$ and $1, 2$ for $\mathbf{y}$. (M1) at $k = 1$ fails for $\mathbf{x} \prec \mathbf{y}$, since $2 > 1$, and (M1) at $k = 2$ fails for $\mathbf{y} \prec \mathbf{x}$, since $2 > 1$.

(b) Take $\phi(t) = \max\{t - 1, 0\}$, convex by Proposition 17.10.3. Then $\sum_i \phi(x_i) = 1 + 0 + 0 = 1$ and $\sum_i \phi(y_i) = 0 + 0 + 0 = 0$, so $1 > 0$. This is the test function of Proposition 20.2.2 at $c = y_1^{\downarrow} = 1$, and it certifies $\mathbf{x} \not\prec \mathbf{y}$.

Take $\psi(t) = \max\{t + 1, 0\}$. Then $\sum_i \psi(x_i) = 3 + 0 + 0 = 3$ and $\sum_i \psi(y_i) = 2 + 2 + 0 = 4$, so $3 < 4$, certifying $\mathbf{y} \not\prec \mathbf{x}$ by the same proposition applied with the roles exchanged, at $c = x_2^{\downarrow} = -1$.

There is no contradiction: Proposition 20.2.2 asks the inequality to hold for **every** convex ϕ. Agreeing on the affine functions and on t^2 is far from agreeing on all of them, and here two hockey sticks pull in opposite directions.

20.3 Symmetric Gauge Functions

The last two sections turned a majorization into an inequality between sums of a convex function. This section turns it into an inequality between **norms**. The norms that work are the ones blind to exactly the information a majorization discards — the order of the entries and their signs — and Section 4 will show that these are precisely the norms a matrix inherits from its singular values.

Throughout, the field is $\mathbb{R}$ and the space is $\mathbb{R}^n$ with the dot product $\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{x}^\top \mathbf{y}$, $n \geq 1$. Majorization $\prec$ and weak majorization $\prec_w$ are Chapter 16 §08's (Definition 16.8.1), and $\mathbf{x}^{\downarrow}$ is the decreasing rearrangement. A **permutation matrix $\mathbf{P}_\sigma$** is Definition 2.6.2; $\mathbf{P}_\sigma \mathbf{x}$ rearranges the entries of $\mathbf{x}$. We write $|\mathbf{x}| = (|x_1|, \ldots, |x_n|)$, and $\mathbf{x} \leq \mathbf{y}$ means $x_i \leq y_i$ for **every** i — the entrywise order of Chapter 17 §05, never the Loewner order. From §01 we use Corollary 20.1.4, which rests on Theorem 20.1.3; the exercises also use §02's Theorem 20.2.1.

20.3.1 What a norm must forget

Chapter 16 §06 measured a Hermitian matrix by its Ky Fan partial sum $s_k(\mathbf{A}) = \lambda_1(\mathbf{A}) + \cdots + \lambda_k(\mathbf{A})$, and Exercise (C2: Partial sums that behave like a norm) asked whether s_k is a norm. On the positive semidefinite matrices it behaves like one; on all Hermitian matrices it fails, because $s_1(\mathrm{diag}(0, -1)) = 0$ with $\mathrm{diag}(0, -1) \neq \mathbf{0}$. The exercise ended by naming the repair: apply s_k to the **singular** values instead of the eigenvalues. Singular values are non-negative, so nothing

can cancel, and the failure disappears.

That repair suggests the shape of the whole chapter's answer. A measurement of a matrix built from its singular values is a function of a list of n non-negative numbers. Two things about that list are accidents of bookkeeping. Its **order** is one: the singular values of a matrix form a multiset, and Chapter 12 chose to write them decreasingly. Its **signs** are the other: a formula that is to extend from non-negative lists to all of $\mathbb{R}^n$, and be a norm there, cannot notice which entries are negative, since $\mathbf{x}$ and the vector obtained by flipping one sign have the same absolute values and must be measured alike.

A symmetric gauge function is a norm that cannot tell the entries of a vector apart by where they sit or which way they point.

Definition 20.3.1 — Symmetric Gauge Function

A **symmetric gauge function** on $\mathbb{R}^n$ is a norm $\Phi\colon \mathbb{R}^n \to \mathbb{R}$ (Definition 15.1.1) such that

(G1) $\Phi(\mathbf{P}_\sigma \mathbf{x}) = \Phi(\mathbf{x})$ for **every** permutation matrix $\mathbf{P}_\sigma$ and every $\mathbf{x} \in \mathbb{R}^n$ (**permutation invariance**);

(G2) $\Phi(\varepsilon_1 x_1, \dots, \varepsilon_n x_n) = \Phi(\mathbf{x})$ for **all** signs $\varepsilon_i \in \{+1, -1\}$ and every $\mathbf{x} \in \mathbb{R}^n$ (**sign invariance**).

In words: (G1) says that shuffling the entries does not change the measurement, and (G2) says that flipping any of their signs does not either. The word **every** does the work in both, and the two clauses are genuinely separate: below are a norm with (G1) and not (G2), and one with (G2) and not (G1). Together they say that $\Phi(\mathbf{x})$ depends only on the multiset $\{|x_1|, \dots, |x_n|\}$, that is,

$$\Phi(\mathbf{x}) = \Phi\big(|\mathbf{x}|^{\downarrow}\big) \qquad (\mathbf{x} \in \mathbb{R}^n), \tag{20.3.1}$$

since $|\mathbf{x}|$ is obtained from $\mathbf{x}$ by (G2) and $|\mathbf{x}|^{\downarrow}$ from $|\mathbf{x}|$ by (G1). Note also that (N2) of Definition 15.1.1 already gives $\Phi(-\mathbf{x}) = \Phi(\mathbf{x})$; (G2) is much stronger, because it flips the signs **one entry at a time**.

Warning. **The word "gauge" is used here in a different sense from Chapter 17 §04.** There, Definition 17.4.1 attached to a convex set K the function $p_K(\mathbf{x}) = \inf\{t > 0 : \mathbf{x} \in tK\}$, which measures a vector by inflating K. That object is not this one. The name "symmetric gauge function" is standard and traditional for Definition 20.3.1, and the two never appear in the same argument in this book; where confusion is possible, this chapter writes Φ and never p_K.

The first examples are the norms already at hand.

Example. (The p-norms, the Ky Fan gauges, and size one)

Check each against Definition 20.3.1.

(a) $\|\cdot\|_p$ for $1 \le p \le \infty$.

(b) For $1 \le k \le n$, the function $\Phi_k(\mathbf{x}) = \sum_{i \le k} |x|_i^{\downarrow}$, the sum of the k largest absolute

values.

(c) On $\mathbb{R}^1$, the function $\Phi(x) = c|x|$ for a constant $c > 0$.

Solution.

(a) These are norms: Example (The 1-, 2- and ∞-norms on F^n) for $p = 1, 2, \infty$, and Corollary 17.11.5 supplies the triangle inequality for the rest. The formulas $\left(\sum_i |x_i|^p\right)^{1/p}$ and $\max_i |x_i|$ are built from the absolute values alone and are unchanged by reordering the sum or the maximum, so (G1) and (G2) hold.

(b) Rewrite the definition as a maximum:

$$\Phi_k(\mathbf{x}) = \max\Big\{\sum_{i\in S}|x_i| \;:\; S \subseteq \{1,\dots,n\},\ |S| = k\Big\},$$

since the largest such sum is the one over the indices of the k largest absolute values. Each function $\mathbf{x} \mapsto \sum_{i\in S}|x_i|$ is non-negative, absolutely homogeneous and subadditive, so the maximum of finitely many of them is too, which gives (N2) and (N3). For (N1), every singleton is contained in some S, so $\Phi_k(\mathbf{x}) \geq \max_i |x_i|$, and $\Phi_k(\mathbf{x}) = 0$ forces $\mathbf{x} = \mathbf{0}$. Both (G1) and (G2) are visible in the displayed formula. At the two ends, $\Phi_1 = \|\cdot\|_\infty$ and $\Phi_n = \|\cdot\|_1$.

(c) A norm on $\mathbb{R}^1$ by inspection. There is only one permutation and $\Phi(-x) = \Phi(x)$, so (G1) and (G2) are automatic: on $\mathbb{R}^1$ **every** norm is a symmetric gauge function. The degenerate case is worth keeping in mind, because it shows that the two clauses carry no information until $n \geq 2$.

The functions in (b) will be used constantly, so they get a name of their own.

Definition 20.3.2 — Ky Fan Gauge

For $1 \leq k \leq n$, the **k-th Ky Fan gauge** on $\mathbb{R}^n$ is

$$\Phi_k(\mathbf{x}) = \sum_{i=1}^{k} |x|_i^{\downarrow},$$

the sum of the k largest absolute values of the entries of $\mathbf{x}$.

Non-examples by minimal change. Each drops exactly one clause.

- *A norm with (G1) and not (G2).* On $\mathbb{R}^2$ let

$$\Phi(\mathbf{x}) = \max\big(|x_1 + x_2|,\ |x_1|,\ |x_2|\big).$$

Each of the three expressions is non-negative, absolutely homogeneous and subadditive, so their maximum is too; and $\Phi(\mathbf{x}) = 0$ forces $x_1 = x_2 = 0$, so Φ is a norm. Swapping x_1 and x_2 permutes the three expressions, so (G1) holds. But $\Phi(1,1) = 2$ while $\Phi(1,-1) = 1$: (G2) fails.

- *A norm with (G2) and not (G1).* On $\mathbb{R}^2$ let $\Phi(\mathbf{x}) = |x_1| + 2|x_2|$. This is a norm, and it is built from absolute values, so (G2) holds. But $\Phi(1,0) = 1$ and $\Phi(0,1) = 2$: (G1) fails.

Why this definition. The two clauses are exactly what a norm needs in order to be computable from an unordered list of non-negative numbers, and nothing more is demanded — in particular,

no relation to any other norm, and no smoothness. Dropping (G1) allows a norm to prefer one coordinate to another, which no measurement of singular values can do, since relabeling the singular values of a matrix is not an operation on the matrix at all. Dropping (G2) allows a norm to see cancellation between coordinates, which is fatal: Section 7 needs Φ evaluated at differences of eigenvalue lists and of singular value lists, whose entries have both signs (Theorem 20.7.2 and Theorem 20.7.4).

> *Quick check.* Is $\Phi(\mathbf{x}) = \max_i x_i$ (no absolute values) a symmetric gauge function on $\mathbb{R}^n$ for $n \geq 2$? Which clause fails first?

> *Solution.* It is not, and it fails before (G1) or (G2) are reached: it is not a norm. Absolute homogeneity (N2) fails at $c = -1$, since $\max_i(-x_i) = -\min_i x_i$, which for $\mathbf{x} = (1, 0)$ is 0 while $\max_i x_i = 1$. Positive definiteness (N1) fails too: $\Phi(-1, -1) = -1 < 0$. Restricted to vectors with non-negative entries the formula is perfectly reasonable, and it equals $\|\mathbf{x}\|_\infty$ there; the definition insists on a norm on all of $\mathbb{R}^n$ precisely so that this kind of one-sided formula is excluded.

20.3.2 A symmetric gauge is monotone

The first payoff is that a symmetric gauge respects the crudest comparison there is: if every entry of $\mathbf{x}$ is smaller in absolute value than the matching entry of $\mathbf{y}$, then $\Phi(\mathbf{x}) \leq \Phi(\mathbf{y})$. This is not automatic for a norm. The function $N(\mathbf{x}) = |x_1 - x_2| + |x_1|$ is a norm on $\mathbb{R}^2$, and $N(1, 0) = 2$ is **larger** than $N(1, 1) = 1$ although $(1, 0)$ is dominated entrywise by $(1, 1)$. Sign invariance is what rules this out.

Proposition 20.3.1 — Symmetric Gauges Are Monotone

Let Φ be a symmetric gauge function on $\mathbb{R}^n$, and let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ satisfy $|x_i| \leq |y_i|$ for every i. Then $\Phi(\mathbf{x}) \leq \Phi(\mathbf{y})$.

> *Idea.* Change one coordinate at a time. Shrinking a single entry towards 0 is taking an average of two vectors: the vector itself and the one with that entry's sign flipped. Sign invariance says those two have the same Φ, and the triangle inequality says the average has no larger one.

> *Proof.* **Step 1: one coordinate.** Suppose $\mathbf{u}, \mathbf{v} \in \mathbb{R}^n$ agree in every coordinate except the j-th, where $|u_j| \leq |v_j|$. If $v_j = 0$ then $u_j = 0$ and $\mathbf{u} = \mathbf{v}$. Otherwise put
>
> $$\theta = \frac{1}{2}\Big(1 + \frac{u_j}{v_j}\Big),$$
>
> which lies in $[0, 1]$ because $|u_j / v_j| \leq 1$. Let $\mathbf{v}'$ be $\mathbf{v}$ with its j-th coordinate negated. Then $\theta v_j + (1 - \theta)(-v_j) = u_j$, while in every other coordinate $\mathbf{v}$ and $\mathbf{v}'$ agree with $\mathbf{u}$, so
>
> $$\mathbf{u} = \theta \mathbf{v} + (1 - \theta)\mathbf{v}'.$$
>
> By (N3) and (N2) of Definition 15.1.1, $\Phi(\mathbf{u}) \leq \theta \Phi(\mathbf{v}) + (1 - \theta)\Phi(\mathbf{v}')$, and $\Phi(\mathbf{v}') = \Phi(\mathbf{v})$ by (G2). Hence $\Phi(\mathbf{u}) \leq \Phi(\mathbf{v})$.

Step 2: all coordinates. Put $\mathbf{z}^{(0)} = \mathbf{y}$ and, for $1 \le j \le n$,

$$\mathbf{z}^{(j)} = (x_1, \dots, x_j, y_{j+1}, \dots, y_n),$$

so that $\mathbf{z}^{(n)} = \mathbf{x}$. Consecutive vectors $\mathbf{z}^{(j-1)}$ and $\mathbf{z}^{(j)}$ agree except in coordinate j, where $|x_j| \le |y_j|$. By Step 1, $\Phi(\mathbf{z}^{(j)}) \le \Phi(\mathbf{z}^{(j-1)})$ for each j. Chaining the n inequalities gives $\Phi(\mathbf{x}) \le \Phi(\mathbf{y})$, as claimed.

■

Only (G2) was used. Permutation invariance is needed for the next step, and there it does all the work.

Quick check. Deduce from Proposition 20.3.1 that $\Phi(\mathbf{x}) \ge |x_j|\,\Phi(\mathbf{e}_j)$ for every j. What does the same proposition give as an upper bound, using $\mathbf{x} = \sum_j x_j \mathbf{e}_j$?

Solution. The vector $x_j\mathbf{e}_j$ has j-th entry x_j and all others 0, so its entries are dominated in absolute value by those of $\mathbf{x}$; Proposition 20.3.1 gives $|x_j|\Phi(\mathbf{e}_j) = \Phi(x_j\mathbf{e}_j) \le \Phi(\mathbf{x})$. For the upper bound the triangle inequality suffices: $\Phi(\mathbf{x}) \le \sum_j |x_j|\Phi(\mathbf{e}_j)$. By (G1) all the numbers $\Phi(\mathbf{e}_j)$ are equal, to $\Phi(\mathbf{e}_1)$ say, so

$$\Phi(\mathbf{e}_1)\|\mathbf{x}\|_\infty \;\le\; \Phi(\mathbf{x}) \;\le\; \Phi(\mathbf{e}_1)\|\mathbf{x}\|_1.$$

Every symmetric gauge is trapped between multiples of $\|\cdot\|_\infty$ and $\|\cdot\|_1$, with the same constant at both ends. Section 4 turns this into the statement that every **normalized** unitarily invariant norm lies between the spectral norm and the trace norm.

Both bounds are cited later, so they are recorded here.

Corollary 20.3.2 — A Symmetric Gauge Is Trapped Between Two Norms

Let Φ be a symmetric gauge function on $\mathbb{R}^n$. Then $\Phi(\mathbf{e}_j) = \Phi(\mathbf{e}_1)$ for every j, and

$$\Phi(\mathbf{e}_1)\|\mathbf{x}\|_\infty \;\le\; \Phi(\mathbf{x}) \;\le\; \Phi(\mathbf{e}_1)\|\mathbf{x}\|_1 \qquad (\mathbf{x} \in \mathbb{R}^n).$$

Proof. Fix j. Some permutation matrix carries $\mathbf{e}_j$ to $\mathbf{e}_1$, so $\Phi(\mathbf{e}_j) = \Phi(\mathbf{e}_1)$ by (G1). The entries of $x_j\mathbf{e}_j$ are dominated in absolute value by those of $\mathbf{x}$, so Proposition 20.3.1 gives

$$|x_j|\,\Phi(\mathbf{e}_1) = \Phi(x_j\mathbf{e}_j) \le \Phi(\mathbf{x}),$$

where the equality is (N2) of Definition 15.1.1; taking the largest $|x_j|$ gives the left-hand inequality. For the right-hand one, $\mathbf{x} = \sum_j x_j\mathbf{e}_j$, so (N3) and (N2) give $\Phi(\mathbf{x}) \le \sum_j |x_j|\Phi(\mathbf{e}_j) = \Phi(\mathbf{e}_1)\|\mathbf{x}\|_1$. This proves the corollary.

■

20.3.3 From weak majorization to a dominating vector

Now for the bridge. A majorization $\mathbf{x} \prec \mathbf{y}$ will be handled by Corollary 20.1.4, which writes $\mathbf{x}$ as an average of rearrangements of $\mathbf{y}$; a norm cannot grow under an average. Weak majorization loses the equality of totals, so $\mathbf{x}$ need not be such an average — $(1,0) \prec_w (2,0)$, but $(1,0)$ is no average of $(2,0)$ and $(0,2)$. What survives is that $\mathbf{x}$ is dominated **entrywise** by something that is such an average, and that is exactly the hypothesis Proposition 20.3.1 wants.

Lemma 20.3.3 — Weak Majorization Is Domination plus Majorization

Let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$. Then $\mathbf{x} \prec_w \mathbf{y}$ if and only if there is a vector $\mathbf{z} \in \mathbb{R}^n$ with

$$\mathbf{x} \le \mathbf{z} \quad \text{entrywise}, \qquad \mathbf{z} \prec \mathbf{y}.$$

If $\mathbf{x}$ has **non-negative** entries, then $\mathbf{z}$ may be taken with non-negative entries as well.

Idea. ($\Leftarrow$) is two easy monotonicity steps. For ($\Rightarrow$), sort both vectors and think of the deficit $\sum_i y_i - \sum_i x_i$ as water to be poured into $\mathbf{x}$. Pouring it into the **top** entries would break the partial-sum inequalities immediately, so pour it into the bottom: raise every entry of $\mathbf{x}$ that lies below a level c up to c, and choose c so that the totals match. Choosing c needs no analysis: on each interval between consecutive entries of $\mathbf{x}$ the total is an affine function of c, so the right c can be written down.

Proof. ($\Leftarrow$) Suppose $\mathbf{x} \le \mathbf{z}$ entrywise and $\mathbf{z} \prec \mathbf{y}$. Fix k and let I be a set of k indices carrying the k largest entries of $\mathbf{x}$, so that $\sum_{i \le k} x_i^{\downarrow} = \sum_{i \in I} x_i$. Then

$$\sum_{i \le k} x_i^{\downarrow} = \sum_{i \in I} x_i \;\le\; \sum_{i \in I} z_i \;\le\; \sum_{i \le k} z_i^{\downarrow},$$

the last step because the sum of **any** k entries of $\mathbf{z}$ is at most the sum of its k largest. Hence $\mathbf{x} \prec_w \mathbf{z}$, and $\mathbf{z} \prec \mathbf{y}$ gives $\sum_{i \le k} z_i^{\downarrow} \le \sum_{i \le k} y_i^{\downarrow}$ for $k < n$ and equality of totals at $k = n$; in both cases $\sum_{i \le k} z_i^{\downarrow} \le \sum_{i \le k} y_i^{\downarrow}$. Combining, $\mathbf{x} \prec_w \mathbf{y}$.

($\Rightarrow$) Suppose $\mathbf{x} \prec_w \mathbf{y}$. Majorization and weak majorization depend only on the decreasing rearrangements (Definition 16.8.1 and the remark after it), and the entrywise relation $\mathbf{x} \le \mathbf{z}$ is preserved by applying one permutation to both sides. So it is enough to construct $\mathbf{z}$ when $\mathbf{x} = \mathbf{x}^{\downarrow}$ and $\mathbf{y} = \mathbf{y}^{\downarrow}$: for general $\mathbf{x}$, choose $\mathbf{P}_\sigma$ with $\mathbf{P}_\sigma \mathbf{x} = \mathbf{x}^{\downarrow}$, build $\mathbf{z}'$ for the pair $(\mathbf{x}^{\downarrow}, \mathbf{y}^{\downarrow})$, and take $\mathbf{z} = \mathbf{P}_\sigma^{-1} \mathbf{z}'$.

So let $x_1 \ge \cdots \ge x_n$ and $y_1 \ge \cdots \ge y_n$ with $\sum_{i \le k} x_i \le \sum_{i \le k} y_i$ for every k. Write $S = \sum_{i=1}^{n} y_i$ and, for $0 \le k \le n-1$,

$$c_k = \frac{S - (x_1 + \cdots + x_k)}{n - k},$$

the level at which the last $n-k$ entries would have to sit for the total to be S. At $k = n-1$ we have $c_{n-1} = S - \sum_{i \le n-1} x_i \ge \sum_{i \le n} x_i - \sum_{i \le n-1} x_i = x_n$, using $\mathbf{x} \prec_w \mathbf{y}$ at $k = n$. So the set of indices $k \in \{0, \dots, n-1\}$ with $c_k \ge x_{k+1}$ is non-empty; let j be its

smallest element and put $c = c_j$. Define

$$\mathbf{z} = (x_1, \dots, x_j, \underbrace{c, \dots, c}_{n-j}).$$

The vector $\mathbf{z}$ *dominates* $\mathbf{x}$. For $i \le j$ the entries agree. For $i > j$, $z_i = c \ge x_{j+1} \ge x_i$, since $\mathbf{x}$ is decreasing and $c \ge x_{j+1}$ by the choice of j. If in addition $\mathbf{x} \ge \mathbf{0}$, then $c \ge x_{j+1} \ge 0$ and every entry of $\mathbf{z}$ is non-negative, which is the last claim of the lemma.

The vector $\mathbf{z}$ *is decreasing.* Only the step from x_j to c is in question, so assume $j \ge 1$. By the minimality of j we have $c_{j-1} < x_j$. Multiplying out the two definitions,

$$(n-j+1)c_{j-1} = S - \sum_{i \le j-1} x_i = (n-j)c_j + x_j,$$

so $(n-j)c = (n-j+1)c_{j-1} - x_j < (n-j+1)x_j - x_j = (n-j)x_j$, and $n - j \ge 1$ gives $c < x_j$. Hence $\mathbf{z} = \mathbf{z}^{\downarrow}$.

The vector $\mathbf{z}$ *is majorized by* $\mathbf{y}$. Its total is $\sum_{i \le j} x_i + (n-j)c = S$ by the definition of c_j, which is (M2). For (M1) with $k \le j$, the first k entries of $\mathbf{z}$ are those of $\mathbf{x}$, so $\sum_{i \le k} z_i = \sum_{i \le k} x_i \le \sum_{i \le k} y_i$. For $k > j$, subtract from the totals: since $\sum_i z_i = \sum_i y_i = S$,

$$\sum_{i \le k} z_i - \sum_{i \le k} y_i = \sum_{i > k} y_i - \sum_{i > k} z_i = \sum_{i > k} y_i - (n-k)c,$$

so it suffices to show $\sum_{i>k} y_i \le (n-k)c$. First, at $k = j$ this holds: from $(n-j)c = S - \sum_{i \le j} x_i$ and $\sum_{i \le j} x_i \le \sum_{i \le j} y_i$,

$$(n-j)c \;\ge\; S - \sum_{i \le j} y_i = \sum_{i > j} y_i.$$

So c is at least the average of the $n-j$ smallest entries of $\mathbf{y}$. Now let $k > j$. Each of the entries $y_{j+1}, \dots, y_k$ is at least each of $y_{k+1}, \dots, y_n$, because $\mathbf{y}$ is decreasing; hence each of them is at least the average A of $y_{k+1}, \dots, y_n$, and therefore

$$\sum_{i > j} y_i = \sum_{i=j+1}^{k} y_i + (n-k)A \;\ge\; (k-j)A + (n-k)A = (n-j)A.$$

Combining, $(n-j)c \ge \sum_{i>j} y_i \ge (n-j)A$, so $c \ge A$ and $(n-k)c \ge (n-k)A = \sum_{i>k} y_i$, as required. This proves $\mathbf{z} \prec \mathbf{y}$ and the lemma.

■

The construction is short enough to run by hand.

Example. (Filling from the bottom)

Let $\mathbf{x} = (4, 1, 1)$ and $\mathbf{y} = (5, 3, 2)$. Verify $\mathbf{x} \prec_w \mathbf{y}$ and produce a $\mathbf{z}$ with $\mathbf{x} \le \mathbf{z}$ and $\mathbf{z} \prec \mathbf{y}$.

Solution. Both vectors are already decreasing. The running totals are $4, 5, 6$ for $\mathbf{x}$ and $5, 8, 10$ for $\mathbf{y}$, and $4 \le 5$, $5 \le 8$, $6 \le 10$, so $\mathbf{x} \prec_w \mathbf{y}$. The totals differ, so $\mathbf{x} \not\prec \mathbf{y}$.

Here $S = 10$ and $n = 3$. The levels are $c_0 = 10/3$ and $c_1 = (10-4)/2 = 3$. Since $c_0 = 10/3 < 4 = x_1$, the index $k = 0$ fails; since $c_1 = 3 \geq 1 = x_2$, the smallest admissible index is $j = 1$, and $c = 3$. Hence

$$\mathbf{z} = (4, 3, 3).$$

Check: $(4,1,1) \leq (4,3,3)$ entrywise; $\mathbf{z}$ is decreasing; its running totals $4, 7, 10$ satisfy $4 \leq 5$, $7 \leq 8$, $10 = 10$, so $\mathbf{z} \prec \mathbf{y}$. The deficit of 4 between the totals was poured entirely into the two bottom entries, which is what keeps the top partial sums under control.

20.3.4 The inequality

Everything is now in place.

Theorem 20.3.4 — Symmetric Gauges Respect Majorization

Let Φ be a symmetric gauge function on $\mathbb{R}^n$.

(a) If $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ and $\mathbf{x} \prec \mathbf{y}$, then $\Phi(\mathbf{x}) \leq \Phi(\mathbf{y})$.

(b) If $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ have **non-negative** entries and $\mathbf{x} \prec_w \mathbf{y}$, then $\Phi(\mathbf{x}) \leq \Phi(\mathbf{y})$.

Idea. For (a), §01 turns $\mathbf{x} \prec \mathbf{y}$ into "$\mathbf{x}$ is an average of rearrangements of $\mathbf{y}$", and a norm never exceeds an average of the values it takes on the points averaged — those values all being $\Phi(\mathbf{y})$, by permutation invariance. For (b), Lemma 20.3.3 inserts a middle vector $\mathbf{z}$: from $\mathbf{x}$ to $\mathbf{z}$ use monotonicity, from $\mathbf{z}$ to $\mathbf{y}$ use (a).

Proof.

(a) By Corollary 20.1.4, $\mathbf{x} \in \operatorname{conv}\{\mathbf{P}_\sigma \mathbf{y} : \sigma \in S_n\}$, so there are weights $t_\sigma \geq 0$ with $\sum_\sigma t_\sigma = 1$ and $\mathbf{x} = \sum_\sigma t_\sigma \mathbf{P}_\sigma \mathbf{y}$. By the triangle inequality (N3) and absolute homogeneity (N2) of Definition 15.1.1, applied to this finite sum,

$$\Phi(\mathbf{x}) \;\leq\; \sum_\sigma t_\sigma \, \Phi(\mathbf{P}_\sigma \mathbf{y}) = \sum_\sigma t_\sigma \, \Phi(\mathbf{y}) = \Phi(\mathbf{y}),$$

where the middle equality is (G1).

(b) By Lemma 20.3.3 there is a $\mathbf{z}$ **with non-negative entries** satisfying $\mathbf{x} \leq \mathbf{z}$ entrywise and $\mathbf{z} \prec \mathbf{y}$. Since $\mathbf{x}$ and $\mathbf{z}$ have non-negative entries, $|x_i| = x_i \leq z_i = |z_i|$ for every i, so Proposition 20.3.1 gives $\Phi(\mathbf{x}) \leq \Phi(\mathbf{z})$. By part (a), $\Phi(\mathbf{z}) \leq \Phi(\mathbf{y})$. This proves the theorem.

■

Part (a) needs no sign condition, and part (b) cannot do without one.

Warning. **Part (b) is false for vectors with negative entries.** Take $\mathbf{x} = (0, -10)$ and $\mathbf{y} = (0, 0)$ in $\mathbb{R}^2$. The decreasing rearrangements are $(0, -10)$ and $(0, 0)$, and the running totals $0, -10$ are at most $0, 0$, so $\mathbf{x} \prec_w \mathbf{y}$. But $\Phi(\mathbf{x}) > 0 = \Phi(\mathbf{y})$ for every norm Φ. The lemma is not at fault — $\mathbf{z} = \mathbf{0}$ does satisfy $\mathbf{x} \leq \mathbf{z}$ and $\mathbf{z} \prec \mathbf{y}$. What fails is the step $\Phi(\mathbf{x}) \leq \Phi(\mathbf{z})$, because Proposition 20.3.1 compares **absolute values**, and $|-10| > |0|$. Weak majorization lets a vector run far in the negative direction, and

a norm measures that; only equality of totals, as in $\prec$, or non-negativity of the entries rules it out. This is why Section 4 applies the theorem to singular values and never to eigenvalues.

The converse of part (b) says that the family of symmetric gauges is strong enough to *detect* weak majorization, and it costs nothing: the Ky Fan gauges Φ_k of Definition 20.3.2 are themselves symmetric gauges (Example (The p-norms, the Ky Fan gauges, and size one) (b)), so the inequalities $\Phi_k(\mathbf{x}) \le \Phi_k(\mathbf{y})$ for every k are among those hypothesized, and for non-negative vectors they are the definition of $\mathbf{x} \prec_w \mathbf{y}$. Exercise C1 below states the two directions together, and Section 6 turns them into a theorem about matrices.

20.3.5 The dual gauge

Chapter 17 §04 gave every norm on $\mathbb{R}^n$ a dual, $\|\mathbf{y}\|_* = \max\{\langle \mathbf{x}, \mathbf{y}\rangle : \|\mathbf{x}\| \le 1\}$ (Definition 17.4.4), and proved that taking the dual twice returns the norm (Theorem 17.4.8). Applied to a symmetric gauge, the construction stays inside the class.

Definition 20.3.3 — Dual Gauge

Let Φ be a symmetric gauge function on $\mathbb{R}^n$. Its **dual gauge** is the dual norm of Definition 17.4.4,

$$\Phi^*(\mathbf{y}) = \max\{\langle \mathbf{x}, \mathbf{y}\rangle : \mathbf{x} \in \mathbb{R}^n,\ \Phi(\mathbf{x}) \le 1\}.$$

Theorem 20.3.5 — The Dual of a Symmetric Gauge

Let Φ be a symmetric gauge function on $\mathbb{R}^n$. Then Φ^* is a symmetric gauge function, and $\Phi^{**} = \Phi$.

Idea. Being a norm and being its own double dual are Chapter 17's, quoted. Only (G1) and (G2) need an argument, and each is the same one: the transformation can be moved off $\mathbf{y}$ and onto $\mathbf{x}$, where it permutes the constraint set $\{\Phi \le 1\}$ onto itself.

Proof. That Φ^* is a norm is Proposition 17.4.6 (a), and $\Phi^{**} = \Phi$ is Theorem 17.4.8; both apply to any norm on $\mathbb{R}^n$.

(G1). Let $\mathbf{P} = \mathbf{P}_\sigma$ be a permutation matrix. By Lemma 2.6.6 (b), $\mathbf{P}^\top = \mathbf{P}^{-1}$, so $\langle \mathbf{x}, \mathbf{P}\mathbf{y}\rangle = \mathbf{x}^\top \mathbf{P}\mathbf{y} = (\mathbf{P}^\top \mathbf{x})^\top \mathbf{y} = \langle \mathbf{P}^\top \mathbf{x}, \mathbf{y}\rangle$. As $\mathbf{x}$ runs over $\{\Phi \le 1\}$, so does $\mathbf{x}' = \mathbf{P}^\top \mathbf{x}$: indeed $\Phi(\mathbf{P}^\top \mathbf{x}) = \Phi(\mathbf{x})$ by (G1) for Φ, and $\mathbf{x} \mapsto \mathbf{P}^\top \mathbf{x}$ is a bijection of $\mathbb{R}^n$. Hence the two maxima are over the same set of numbers, and $\Phi^*(\mathbf{P}\mathbf{y}) = \Phi^*(\mathbf{y})$.

(G2). Fix signs $\varepsilon_i = \pm 1$ and write $\mathbf{y}_\varepsilon = (\varepsilon_1 y_1, \dots, \varepsilon_n y_n)$. Then $\langle \mathbf{x}, \mathbf{y}_\varepsilon\rangle = \sum_i x_i \varepsilon_i y_i = \langle \mathbf{x}_\varepsilon, \mathbf{y}\rangle$, and $\mathbf{x} \mapsto \mathbf{x}_\varepsilon$ is a bijection of $\mathbb{R}^n$ with $\Phi(\mathbf{x}_\varepsilon) = \Phi(\mathbf{x})$ by (G2) for Φ. So again the two maxima range over the same numbers, and $\Phi^*(\mathbf{y}_\varepsilon) = \Phi^*(\mathbf{y})$. This proves the theorem.

■

So duality is an involution of the set of symmetric gauge functions on $\mathbb{R}^n$. The examples are

Chapter 17's: by Proposition 17.4.7 and Theorem 17.11.6,

$$(\|\cdot\|_p)^* = \|\cdot\|_q \qquad \left(\tfrac{1}{p}+\tfrac{1}{q}=1,\ 1\le p\le\infty\right),$$

so $\|\cdot\|_1$ and $\|\cdot\|_\infty$ are dual to each other and $\|\cdot\|_2$ is self-dual. In the notation of Definition 20.3.2 that says $\Phi_1^* = \Phi_n$ and $\Phi_n^* = \Phi_1$; exercise C2 below computes Φ_k^* for the k in between. Section 5 will find the matrix meaning of all of this: the dual of a unitarily invariant norm, taken with respect to the trace pairing, is the norm attached to the dual gauge.

20.3.6 Exercises

20.3.6.1 A. Check your understanding

Exercise A1.

(a) State Definition 20.3.1, naming both invariance clauses and the space the function is defined on.

(b) Explain why $\Phi(\mathbf{x}) = \Phi(|\mathbf{x}|^{\downarrow})$ for every symmetric gauge and every $\mathbf{x}$.

(c) True or false, with a reason: if $\mathbf{x} \prec_w \mathbf{y}$ in $\mathbb{R}^n$, then $\|\mathbf{x}\|_2 \le \|\mathbf{y}\|_2$.

(d) Name the hypothesis in Theorem 20.3.4 (b) that part (a) does without, and say where it is used in the proof.

Solution.

(a) A symmetric gauge function on $\mathbb{R}^n$ is a norm $\Phi\colon \mathbb{R}^n \to \mathbb{R}$ satisfying (G1) $\Phi(\mathbf{P}_\sigma \mathbf{x}) = \Phi(\mathbf{x})$ for every permutation matrix, and (G2) $\Phi(\varepsilon_1 x_1, \dots, \varepsilon_n x_n) = \Phi(\mathbf{x})$ for all choices of signs $\varepsilon_i = \pm 1$.

(b) This is Eq. 20.3.1. Replacing each x_i by $|x_i|$ is a choice of signs, so (G2) gives $\Phi(\mathbf{x}) = \Phi(|\mathbf{x}|)$; sorting $|\mathbf{x}|$ decreasingly is applying a permutation matrix, so (G1) gives $\Phi(|\mathbf{x}|) = \Phi(|\mathbf{x}|^{\downarrow})$.

(c) False in general. Take $\mathbf{x} = (0, -10)$ and $\mathbf{y} = (0, 0)$: then $\mathbf{x} \prec_w \mathbf{y}$ but $\|\mathbf{x}\|_2 = 10 > 0$. It is true when $\mathbf{x}$ and $\mathbf{y}$ have non-negative entries, by Theorem 20.3.4 (b) with $\Phi = \|\cdot\|_2$.

(d) Non-negativity of the entries. It is used to pass from $\mathbf{x} \le \mathbf{z}$ entrywise to $|x_i| \le |z_i|$, which is what Proposition 20.3.1 requires; without it, $x_i \le z_i$ says nothing about absolute values.

20.3.6.2 B. Practice

Exercise B1: Which of these are symmetric gauges.

Determine which of the following are symmetric gauge functions on $\mathbb{R}^3$. Justify your answer, naming the exact clause that fails when one does.

(a) $\Phi(\mathbf{x}) = |x_1| + |x_2| + |x_3|$.

(b) $\Phi(\mathbf{x}) = |x|_1^{\downarrow} + |x|_2^{\downarrow}$.

(c) $\Phi(\mathbf{x}) = \left(|x_1|^{1/2} + |x_2|^{1/2} + |x_3|^{1/2}\right)^2$.

(d) $\Phi(\mathbf{x}) = \max(|x_1|, |x_2|) + |x_3|$.

(e) $\Phi(\mathbf{x}) = |x_1 + x_2 + x_3| + |x_1 - x_2| + |x_2 - x_3|$.

Solution.

(a) Yes: this is $\|\cdot\|_1 = \Phi_3$, Example (The p-norms, the Ky Fan gauges, and size one) (a).

(b) Yes: this is the Ky Fan gauge Φ_2 of Definition 20.3.2, checked in Example (The p-norms, the Ky Fan gauges, and size one) (b).

(c) No. It is non-negative, absolutely homogeneous, permutation invariant and sign invariant, but (N3) fails: with $\mathbf{x} = (1, 0, 0)$ and $\mathbf{y} = (0, 1, 0)$ we get $\Phi(\mathbf{x}) = \Phi(\mathbf{y}) = 1$ while $\Phi(\mathbf{x} + \mathbf{y}) = (1 + 1)^2 = 4 > 2$. It is not a norm, so it is not a symmetric gauge.

(d) No. It is a norm — a sum of two seminorms, positive definite because each coordinate appears — and it is sign invariant, so (G2) holds. But (G1) fails: $\Phi(1, 1, 0) = 1$ while $\Phi(1, 0, 1) = 2$.

(e) No. It is a norm: it is non-negative and absolutely homogeneous, subadditive as a sum of three seminorms, and $\Phi(\mathbf{x}) = 0$ forces $x_1 = x_2 = x_3$ and $|3x_1| = 0$, hence $\mathbf{x} = \mathbf{0}$. Both invariance clauses fail. For (G1), $\Phi(1, 1, 0) = 2 + 0 + 1 = 3$ while $\Phi(1, 0, 1) = 2 + 1 + 1 = 4$. For (G2), $\Phi(1, 1, 1) = 3 + 0 + 0 = 3$ while $\Phi(1, -1, 1) = 1 + 2 + 2 = 5$.

Exercise B2: Filling from the bottom.

Let $\mathbf{x} = (6, 2, 2, 0)$ and $\mathbf{y} = (7, 4, 3, 2)$ in $\mathbb{R}^4$.

(a) Verify that $\mathbf{x} \prec_w \mathbf{y}$ and that $\mathbf{x} \not\prec \mathbf{y}$.

(b) Carry out the construction in the proof of Lemma 20.3.3 to produce $\mathbf{z}$ with $\mathbf{x} \le \mathbf{z}$ and $\mathbf{z} \prec \mathbf{y}$.

(c) Hence bound $\|\mathbf{x}\|_2$ by $\|\mathbf{y}\|_2$ without computing either, and then check the bound numerically.

Solution.

(a) Both are decreasing. Running totals: $6, 8, 10, 10$ for $\mathbf{x}$ and $7, 11, 14, 16$ for $\mathbf{y}$. Each is at most the corresponding one, so $\mathbf{x} \prec_w \mathbf{y}$; the totals 10 and 16 differ, so $\mathbf{x} \not\prec \mathbf{y}$.

(b) Here $S = 16$ and $n = 4$, so $c_0 = 16/4 = 4$, $c_1 = (16 - 6)/3 = 10/3$, $c_2 = (16 - 8)/2 = 4$, $c_3 = 16 - 10 = 6$. Test $c_k \ge x_{k+1}$: $c_0 = 4 < 6 = x_1$, so $k = 0$ fails; $c_1 = 10/3 \ge 2 = x_2$, so $j = 1$ and $c = 10/3$. Hence

$$\mathbf{z} = \left(6, \tfrac{10}{3}, \tfrac{10}{3}, \tfrac{10}{3}\right).$$

Check: $\mathbf{x} \le \mathbf{z}$ entrywise; $\mathbf{z}$ is decreasing; running totals $6, \frac{28}{3}, \frac{38}{3}, 16$, and $6 \le 7$, $\frac{28}{3} \approx 9.33 \le 11$, $\frac{38}{3} \approx 12.67 \le 14$, $16 = 16$. So $\mathbf{z} \prec \mathbf{y}$.

(c) Both vectors have non-negative entries, so Theorem 20.3.4 (b) with $\Phi = \|\cdot\|_2$ gives $\|\mathbf{x}\|_2 \le \|\mathbf{y}\|_2$. Numerically $\|\mathbf{x}\|_2 = \sqrt{36 + 4 + 4} = \sqrt{44}$ and $\|\mathbf{y}\|_2 = \sqrt{49 + 16 + 9 + 4} = \sqrt{78}$, and $44 \le 78$. The intermediate vector satisfies $\|\mathbf{z}\|_2^2 = 36 + 3 \cdot \frac{100}{9} = \frac{208}{3} \approx 69.3$, between the two, as the proof predicts.

Exercise B3: Monotonicity used twice.

Let Φ be a symmetric gauge function on $\mathbb{R}^3$ with $\Phi(\mathbf{e}_1) = 1$.

(a) Prove that $1 \le \Phi(1,1,0) \le 2$.

(b) Prove that $\Phi(2,1,1) \le \Phi(3,1,0)$.

(c) Give a symmetric gauge for which the inequality in (b) is strict, and one for which it is an equality.

Solution.

(a) The Quick check following Proposition 20.3.1 gives $\Phi(\mathbf{e}_1)\|\mathbf{x}\|_\infty \le \Phi(\mathbf{x}) \le \Phi(\mathbf{e}_1)\|\mathbf{x}\|_1$. With $\mathbf{x} = (1,1,0)$ and $\Phi(\mathbf{e}_1) = 1$ this reads $1 \le \Phi(1,1,0) \le 2$.

(b) Both vectors are decreasing with total 4, and the running totals $2, 3$ of $(2,1,1)$ are at most the running totals $3, 4$ of $(3,1,0)$, so $(2,1,1) \prec (3,1,0)$. Now Theorem 20.3.4 (a) applies.

(c) Strict for $\Phi = \|\cdot\|_2$: $\sqrt{6} < \sqrt{10}$. It is also strict for $\Phi = \Phi_2$, where the values are 3 and 4. Equality holds for $\Phi = \|\cdot\|_1 = \Phi_3$, where both values are 4: any two non-negative vectors with the same total have the same 1-norm, so a majorization can never be detected by Φ_3 alone. This is the general shape of the equality case — the top gauge sees only the total, which a majorization preserves.

20.3.6.3 C. Going deeper

Exercise C1: Symmetric gauges detect weak majorization.

Let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ have non-negative entries.

(a) Prove that $\mathbf{x} \prec_w \mathbf{y}$ if and only if $\Phi(\mathbf{x}) \le \Phi(\mathbf{y})$ for **every** symmetric gauge function Φ on $\mathbb{R}^n$.

(b) Prove that $\mathbf{x} \prec \mathbf{y}$ if and only if $\mathbf{x} \prec_w \mathbf{y}$ and $\sum_i x_i = \sum_i y_i$.

(c) Deduce that $\mathbf{x} \prec \mathbf{y}$ if and only if $\Phi(\mathbf{x}) \le \Phi(\mathbf{y})$ for every symmetric gauge and $\sum_i x_i = \sum_i y_i$.

Hint for (a): only finitely many gauges are needed.

Solution.

(a) ($\Rightarrow$) is Theorem 20.3.4 (b). ($\Leftarrow$) Apply the hypothesis to the Ky Fan gauges Φ_k of Definition 20.3.2, $k = 1, \dots, n$. Since $\mathbf{x}$ and $\mathbf{y}$ have non-negative entries, $|\mathbf{x}|^{\downarrow} = \mathbf{x}^{\downarrow}$ and likewise for $\mathbf{y}$, so $\Phi_k(\mathbf{x}) = \sum_{i \le k} x_i^{\downarrow}$ and $\Phi_k(\mathbf{y}) = \sum_{i \le k} y_i^{\downarrow}$. The inequalities $\Phi_k(\mathbf{x}) \le \Phi_k(\mathbf{y})$ for $k = 1, \dots, n$ are exactly (M1) extended to $k = n$, which is Definition 16.8.1's $\mathbf{x} \prec_w \mathbf{y}$.

(b) This is a restatement of Definition 16.8.1: $\mathbf{x} \prec \mathbf{y}$ means (M1) for $k \le n-1$ together with equality of totals, and $\mathbf{x} \prec_w \mathbf{y}$ means (M1) for $k \le n$. Given equality of totals, the case $k = n$ of (M1) is automatic, so the two lists of conditions agree.

(c) Combine (a) and (b): $\mathbf{x} \prec \mathbf{y}$ holds exactly when $\mathbf{x} \prec_w \mathbf{y}$ and the totals are equal,

and by (a) the first of these is equivalent to $\Phi(\mathbf{x}) \le \Phi(\mathbf{y})$ for every symmetric gauge.

Exercise C2: The dual of a Ky Fan gauge.

Fix $1 \le k \le n$ and let Φ_k be the Ky Fan gauge of Definition 20.3.2.

(a) Prove that $\Phi_k^*(\mathbf{y}) \ge \max\bigl(\|\mathbf{y}\|_\infty,\ \frac{1}{k}\|\mathbf{y}\|_1\bigr)$ by exhibiting two competitors.

(b) Let $\Phi_k(\mathbf{x}) \le 1$ and let $\mathbf{y}$ have non-negative, decreasing entries. Put $t = |x|_k^{\downarrow}$ and split each $|x_i|$ as $(|x_i| - t)_+ + \min(|x_i|, t)$. Prove that $\sum_i (|x_i| - t)_+ \le 1 - kt$ and that $0 \le t \le 1/k$.

(c) Deduce $\Phi_k^*(\mathbf{y}) = \max\bigl(\|\mathbf{y}\|_\infty, \frac{1}{k}\|\mathbf{y}\|_1\bigr)$, and check the cases $k = 1$ and $k = n$ against Proposition 17.4.7.

Solution.

(a) The vector $\mathbf{e}_1$ has $\Phi_k(\mathbf{e}_1) = 1$; replacing it by $\pm\mathbf{e}_j$ with the sign of y_j, for a j where $|y_j|$ is largest, gives $\langle \mathbf{x}, \mathbf{y}\rangle = \|\mathbf{y}\|_\infty$. The vector $\mathbf{x}$ with $x_i = \pm 1/k$, the sign of y_i, has $\Phi_k(\mathbf{x}) = k \cdot \frac{1}{k} = 1$ and $\langle \mathbf{x}, \mathbf{y}\rangle = \frac{1}{k}\|\mathbf{y}\|_1$. So $\Phi_k^*(\mathbf{y})$ is at least both numbers.

(b) Since $|x|^{\downarrow}$ is decreasing, $(|x|_i^{\downarrow} - t)_+ = 0$ for $i > k$, so

$$\sum_i (|x_i| - t)_+ = \sum_{i \le k} \bigl(|x|_i^{\downarrow} - t\bigr) = \Phi_k(\mathbf{x}) - kt \le 1 - kt.$$

Also $kt \le \sum_{i \le k} |x|_i^{\downarrow} = \Phi_k(\mathbf{x}) \le 1$, so $0 \le t \le 1/k$.

(c) By Theorem 20.3.5, Φ_k^* is a symmetric gauge, so its value at $\mathbf{y}$ depends only on $|\mathbf{y}|^{\downarrow}$; and replacing $\mathbf{x}$ by $|\mathbf{x}|$ leaves $\Phi_k(\mathbf{x})$ unchanged and does not decrease $\langle \mathbf{x}, \mathbf{y}\rangle$ when $\mathbf{y} \ge \mathbf{0}$. So we may assume $\mathbf{y}$ has non-negative decreasing entries and $\mathbf{x} \ge \mathbf{0}$. With t as in (b), and using $y_i \le y_1 = \|\mathbf{y}\|_\infty$ in the first sum and $\min(x_i, t) \le t$ in the second,

$$\langle \mathbf{x}, \mathbf{y}\rangle \le \|\mathbf{y}\|_\infty (1 - kt) + t\|\mathbf{y}\|_1 = \|\mathbf{y}\|_\infty + t\bigl(\|\mathbf{y}\|_1 - k\|\mathbf{y}\|_\infty\bigr).$$

If $\|\mathbf{y}\|_1 \le k\|\mathbf{y}\|_\infty$, the bracket is at most 0 and $t \ge 0$, so the right side is at most $\|\mathbf{y}\|_\infty$. If $\|\mathbf{y}\|_1 > k\|\mathbf{y}\|_\infty$, the right side increases with t, and $t \le 1/k$ gives the bound $\|\mathbf{y}\|_\infty + \frac{1}{k}\|\mathbf{y}\|_1 - \|\mathbf{y}\|_\infty = \frac{1}{k}\|\mathbf{y}\|_1$. In both cases $\langle \mathbf{x}, \mathbf{y}\rangle \le \max(\|\mathbf{y}\|_\infty, \frac{1}{k}\|\mathbf{y}\|_1)$, which with (a) gives equality.

For $k = 1$, $\Phi_1 = \|\cdot\|_\infty$ and the formula gives $\max(\|\mathbf{y}\|_\infty, \|\mathbf{y}\|_1) = \|\mathbf{y}\|_1$, matching Proposition 17.4.7 (b). For $k = n$, $\Phi_n = \|\cdot\|_1$ and the formula gives $\max(\|\mathbf{y}\|_\infty, \frac{1}{n}\|\mathbf{y}\|_1) = \|\mathbf{y}\|_\infty$, matching part (a) of the same proposition.

Exercise C3: Where each hypothesis is used.

(a) Determine whether there is a norm on $\mathbb{R}^2$ that is permutation invariant and satisfies $\Phi(\mathbf{x}) \le \Phi(\mathbf{y})$ whenever $|x_i| \le |y_i|$ for all i, but is **not** a symmetric gauge function. Justify your answer.

(b) Theorem 20.3.4 (b) needs non-negative entries, while Lemma 20.3.3 does not. Locate the exact step of the proof of the theorem that uses the hypothesis, and

explain why $\mathbf{x} = (0, -10) \prec_w (0, 0) = \mathbf{y}$ breaks it even though the lemma supplies a perfectly good $\mathbf{z}$.

(c) Let $\mathbf{x} \prec_w \mathbf{y}$ with $\mathbf{x} = \mathbf{x}^{\downarrow}$, and let $\mathbf{z}$ be the vector built in the proof of Lemma 20.3.3. Prove that $\mathbf{z} \prec \mathbf{z}'$ for **every** $\mathbf{z}'$ with $\mathbf{x} \le \mathbf{z}'$ and $\sum_i z'_i = \sum_i y_i$, and deduce that $\sum_i \phi(z_i) \le \sum_i \phi(z'_i)$ for every convex ϕ. *Hint: compare top partial sums; Theorem 20.2.1 does the last step.*

Solution.

(a) There is none: monotonicity in the stated sense already forces (G2). If $|x_i| \le |y_i|$ implies $\Phi(\mathbf{x}) \le \Phi(\mathbf{y})$, then for any signs the vectors $\mathbf{x}$ and $(\varepsilon_1 x_1, \dots, \varepsilon_n x_n)$ dominate each other entrywise in absolute value, so their Φ-values are equal, which is (G2). With permutation invariance this is Definition 20.3.1. So the conclusion of Proposition 20.3.1 is not merely implied by (G2): for any norm the two are equivalent.

(b) The step is $\Phi(\mathbf{x}) \le \Phi(\mathbf{z})$, which invokes Proposition 20.3.1 and therefore needs $|x_i| \le |z_i|$, not $x_i \le z_i$. For $\mathbf{x} = (0, -10)$ and $\mathbf{y} = (0, 0)$ the lemma does supply a $\mathbf{z}$, namely $\mathbf{z} = \mathbf{0}$: indeed $\mathbf{z} \prec \mathbf{y}$ and $\mathbf{x} \le \mathbf{z}$. But $|x_2| = 10 > 0 = |z_2|$, so Proposition 20.3.1 does not apply, and it must not: $\Phi(\mathbf{x}) > 0 = \Phi(\mathbf{z})$ for every norm. When the entries are non-negative, $x_i \le z_i$ and $|x_i| \le |z_i|$ say the same thing, and the gap closes.

(c) Write $S = \sum_i y_i$ and recall $\mathbf{z} = (x_1, \dots, x_j, c, \dots, c)$, decreasing, with $\sum_i z_i = S$. Let $\mathbf{z}'$ satisfy $\mathbf{x} \le \mathbf{z}'$ and $\sum_i z'_i = S$, and write $M_1 \ge \cdots \ge M_n$ for its entries in decreasing order. Since the totals agree, (M2) holds, and it remains to check (M1) for $1 \le k \le n - 1$.

Case $k \le j$. Then $\sum_{i \le k} z_i = \sum_{i \le k} x_i \le \sum_{i \le k} z'_i \le \sum_{i \le k} M_i$, the first inequality from $\mathbf{x} \le \mathbf{z}'$ and the second because no k entries of $\mathbf{z}'$ add up to more than its k largest.

Case $k > j$. Here $\sum_{i \le k} z_i = S - (n - k)c$, so the claim is $\sum_{i > k} M_i \le (n - k)c$. Suppose not. Then the average of $M_{k+1}, \dots, M_n$ exceeds c, and M_{k+1}, being the largest of them, satisfies $M_{k+1} > c$; hence $M_i > c$ for every $i \le k + 1$. Also $\sum_{i \le j} M_i \ge \sum_{i \le j} x_i$, by the argument of the previous case. Therefore

$$\begin{aligned} S = \sum_i M_i &= \sum_{i \le j} M_i + \sum_{i=j+1}^{k} M_i + \sum_{i > k} M_i \\ &> \sum_{i \le j} x_i + (k - j)c + (n - k)c = S, \end{aligned}$$

the last equality being $\sum_{i \le j} x_i + (n - j)c = S$, which defined c. This contradiction proves the case.

So $\mathbf{z} \prec \mathbf{z}'$, and Theorem 20.2.1 gives $\sum_i \phi(z_i) \le \sum_i \phi(z'_i)$ for every convex ϕ. In words: among all admissible ways of raising $\mathbf{x}$ to the required total, the flat filling is the most even one.

20.4 Unitarily Invariant Norms

Chapter 15 ended its survey of norms with a list of what it had left undone, and one entry read: "It has not said which norms are invariant under unitary multiplication, which is Chapter 20." This section says it. The answer is that such a norm is nothing but a symmetric gauge function applied to the singular values, so §03's inequality transfers wholesale from vectors to matrices — and the Ky Fan functionals that failed to be norms on Hermitian matrices become norms as soon as they are read on singular values instead.

Throughout, $F = \mathbb{R}$ **or** $F = \mathbb{C}$, $\mathbf{A}, \mathbf{B} \in M_{m\times n}(F)$, $p = \min(m, n)$, and $\sigma(\mathbf{A}) = (\sigma_1(\mathbf{A}), \dots, \sigma_p(\mathbf{A})) \in \mathbb{R}^p$ is the decreasing list of singular values (Definition 12.8.1). Symmetric gauge functions are §03's (Definition 20.3.1) and live on $\mathbb{R}^p$. For $\mathbf{x} \in \mathbb{R}^p$ we write

$$\operatorname{diag}_{m,n}(\mathbf{x}) \in M_{m\times n}(F)$$

for the matrix with $x_1, \dots, x_p$ down the main diagonal and every other entry 0; for $m = n$ this is the usual $\operatorname{diag}(x_1, \dots, x_n)$. Finally, one consequence of Theorem 12.8.1 and Theorem 12.8.2 is used constantly: if $\mathbf{A} = \mathbf{W}\mathbf{\Sigma}\mathbf{X}^*$ is a singular value decomposition and $\mathbf{U} \in M_m(F)$, $\mathbf{V} \in M_n(F)$ are unitary, then

$$\mathbf{U}\mathbf{A}\mathbf{V} = (\mathbf{U}\mathbf{W})\,\mathbf{\Sigma}\,(\mathbf{V}^*\mathbf{X})^*$$

is again of that shape, with $\mathbf{U}\mathbf{W}$ and $\mathbf{V}^*\mathbf{X}$ unitary, so

$$\sigma(\mathbf{U}\mathbf{A}\mathbf{V}) = \sigma(\mathbf{A}). \tag{20.4.1}$$

20.4.1 Norms that do not see the unitary factors

Two matrix norms in the book already ignore unitary factors. The Frobenius norm does, by Lemma 11.11.1; the spectral norm does, by Lemma 19.9.1 (c). Both facts were proved separately and both were used the same way: to replace $\mathbf{A}$ by $\mathbf{\Sigma}$ and reduce a question about a matrix to a question about a list of numbers. That is a property worth isolating, and it is the property Chapter 15 left unnamed.

A norm is unitarily invariant when rotating the domain and the codomain does not change the measurement.

Definition 20.4.1 — Unitarily Invariant Norm

A **unitarily invariant norm** on $M_{m\times n}(F)$ is a norm $|||\cdot|||$ on $M_{m\times n}(F)$, regarded as a vector space over F, such that

$$|||\mathbf{U}\mathbf{A}\mathbf{V}||| = |||\mathbf{A}|||$$

for **every** $\mathbf{A} \in M_{m\times n}(F)$ and **all** unitary $\mathbf{U} \in M_m(F)$, $\mathbf{V} \in M_n(F)$.

The triple bars are standard and are used from here on for a norm known to be unitarily invariant; a single bar with a subscript, as in $\|\mathbf{A}\|_2$ or $\|\mathbf{A}\|_F$, keeps naming a specific one. In words: the condition is not invariance under similarity, and not invariance under transposition; it is invariance under multiplying on the **left** by any unitary and on the **right** by any unitary, independently. The two unitaries are unrelated, which is what makes the condition strong. Asking only for invariance under $\mathbf{A} \mapsto \mathbf{U}\mathbf{A}\mathbf{U}^*$, with the same unitary on both sides, is a much

weaker demand: $|\operatorname{tr}\mathbf{A}|$ has it, since $\operatorname{tr}(\mathbf{UAU}^*) = \operatorname{tr}\mathbf{A}$ by Theorem 0.9.6 (3), yet it is not determined by $\sigma(\mathbf{A})$, because $\mathbf{I}_2$ and $\operatorname{diag}(1,-1)$ both have singular values $1,1$ while their traces have absolute values 2 and 0.

Example. (The two familiar norms)

Check each against Definition 20.4.1.

(a) The Frobenius norm $\|\mathbf{A}\|_F$.
(b) The spectral norm $\|\mathbf{A}\|_2$.

Solution.

(a) It is a norm, being the norm of the Frobenius inner product of Chapter 10 §01, and $\|\mathbf{UAV}\|_F = \|\mathbf{A}\|_F$ is Lemma 11.11.1.
(b) It is a norm by Theorem 15.3.2 (b), and Lemma 19.9.1 (c) gives $\|\mathbf{UAV}\|_2 = \|\mathbf{A}\|_2$ for unitary $\mathbf{U},\mathbf{V}$. By Theorem 15.3.3 (c), $\|\mathbf{A}\|_2 = \sigma_1(\mathbf{A})$, so this norm too is a function of $\sigma(\mathbf{A})$ alone — and Eq. 20.4.1 gives a second proof of its invariance.

Both are built from $\sigma(\mathbf{A})$. The largest singular value and the square root of the sum of their squares are two entries in a whole family, and the family is the point of the section.

Definition 20.4.2 — Ky Fan k-Norms

For $1 \le k \le p$, the **Ky Fan k-norm** of $\mathbf{A} \in M_{m\times n}(F)$ is

$$\|\mathbf{A}\|_{(k)} = \sum_{i=1}^{k} \sigma_i(\mathbf{A}),$$

the sum of the k largest singular values. For $k = 1$ it is the spectral norm $\|\mathbf{A}\|_2$; for $k = p$ it is called the **trace norm**.

Chapter 16 §06 measured a Hermitian matrix by $s_k(\mathbf{A}) = \lambda_1(\mathbf{A}) + \cdots + \lambda_k(\mathbf{A})$ and found in Exercise (C2: Partial sums that behave like a norm) that this is no norm: $s_1(\operatorname{diag}(0,-1)) = 0$ although $\operatorname{diag}(0,-1) \neq \mathbf{0}$. The exercise said that "the repair is to apply N_k [its name there for s_k] to the singular values instead of the eigenvalues, which is what Chapter 20 does". Definition 20.4.2 is that repair, and the repair works. Positive definiteness now holds because singular values are non-negative, so they can only sum to 0 by all vanishing, which by Theorem 12.8.1 forces $\mathbf{A} = \mathbf{0}$; absolute homogeneity holds because $(c\mathbf{A})^*(c\mathbf{A}) = |c|^2\mathbf{A}^*\mathbf{A}$ gives $\sigma(c\mathbf{A}) = |c|\sigma(\mathbf{A})$ through Definition 12.8.1; and unitary invariance is Eq. 20.4.1. The triangle inequality is the one axiom still outstanding, and Lemma 20.4.2 below supplies it.

Non-examples by minimal change. Both are honest norms on $M_2(\mathbb{R})$ that fail only the invariance clause, and one witness refutes both. Let

$$\mathbf{U} = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix},$$

a rotation through half a right angle, which is orthogonal since its columns are orthonormal.

- *The entrywise maximum* $N(\mathbf{A}) = \max_{i,j}|a_{ij}|$ is a norm (it is the ∞-norm of the entry list).

But $N(\mathbf{I}_2) = 1$ while $N(\mathbf{U}\mathbf{I}_2\mathbf{I}_2) = N(\mathbf{U}) = 1/\sqrt{2}$.

- *The operator* 1*-norm* $\|\mathbf{A}\|_1$, the largest column sum of absolute values (Theorem 15.3.3 (a)), is a norm. But $\|\mathbf{I}_2\|_1 = 1$ while $\|\mathbf{U}\|_1 = 1/\sqrt{2} + 1/\sqrt{2} = \sqrt{2}$.

Both failures are visible in the same picture: $\mathbf{I}_2$ and $\mathbf{U}$ have the same singular values, namely $1, 1$, because both are orthogonal, and a unitarily invariant norm is therefore forced to give them the same value. A norm that reads individual entries or individual columns is reading a basis, and a unitary change of basis is exactly what Definition 20.4.1 forbids it to notice.

Why this definition. The clause is exactly what makes a norm a function of the singular values and nothing else, as the next lemma shows; that is its whole purpose. Weakening it to one-sided invariance $|||\mathbf{U}\mathbf{A}||| = |||\mathbf{A}|||$ is not enough. The largest Euclidean length among the columns of $\mathbf{A}$ is a norm with that property, since a unitary matrix preserves the length of each column; but it gives $\operatorname{diag}(2,1)$ the value 2, while $\operatorname{diag}(2,1)\mathbf{U}^\top = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 2 & 2 \\ -1 & 1 \end{smallmatrix}\right)$ has both columns of length $\sqrt{5/2}$, and the two matrices have the same singular values. Strengthening it to include all invertible $\mathbf{U}, \mathbf{V}$ is far too much, since every non-zero matrix of a given rank would then have the same norm.

> *Quick check.* Is $\mathbf{A} \mapsto \sigma_2(\mathbf{A})$ a unitarily invariant norm on $M_2(\mathbb{R})$? Is $\mathbf{A} \mapsto \sigma_1(\mathbf{A}) - \sigma_2(\mathbf{A})$?

> *Solution.* Neither, and both fail (N1) of Definition 15.1.1 rather than the invariance clause: they are unitarily invariant by Eq. 20.4.1, but they are not norms. The matrix $\mathbf{A} = \mathbf{e}_1\mathbf{e}_1^\top$ has $\sigma(\mathbf{A}) = (1, 0)$, so $\sigma_2(\mathbf{A}) = 0$ with $\mathbf{A} \neq \mathbf{0}$. The identity has $\sigma(\mathbf{I}_2) = (1, 1)$, so $\sigma_1(\mathbf{I}_2) - \sigma_2(\mathbf{I}_2) = 0$ with $\mathbf{I}_2 \neq \mathbf{0}$. This is the same failure Chapter 16 met with s_k, and it says that not every symmetric-looking formula in the singular values is a norm; the correspondence below says exactly which are.

20.4.2 A unitarily invariant norm is a function of the singular values

Lemma 20.4.1 — The Gauge of a Unitarily Invariant Norm

Let $|||\cdot|||$ be a unitarily invariant norm on $M_{m\times n}(F)$ and define

$$\Phi(\mathbf{x}) = \left|\left|\left|\operatorname{diag}_{m,n}(\mathbf{x})\right|\right|\right| \qquad (\mathbf{x} \in \mathbb{R}^p).$$

Then Φ is a symmetric gauge function on $\mathbb{R}^p$, and

$$|||\mathbf{A}||| = \Phi\big(\sigma(\mathbf{A})\big) \qquad \text{for every } \mathbf{A} \in M_{m\times n}(F).$$

In particular $|||\mathbf{A}|||$ depends on $\mathbf{A}$ only through $\sigma(\mathbf{A})$.

> *Idea.* The map $\mathbf{x} \mapsto \operatorname{diag}_{m,n}(\mathbf{x})$ is linear and injective, so the norm axioms for Φ are inherited entry for entry. The two invariance clauses are the two families of unitary matrices that act diagonally: a permutation matrix on each side rearranges the diagonal, a diagonal matrix of signs on one side flips its signs. The last formula is the singular value decomposition, read once.

Proof. **Φ is a norm.** The map $L(\mathbf{x}) = \operatorname{diag}_{m,n}(\mathbf{x})$ is linear from $\mathbb{R}^p$ to $M_{m\times n}(F)$ and injective, since $L(\mathbf{x}) = \mathbf{0}$ reads off as $\mathbf{x} = \mathbf{0}$. Hence $\Phi = |||\cdot||| \circ L$ satisfies (N1) — $\Phi(\mathbf{x}) = 0$ gives $L(\mathbf{x}) = \mathbf{0}$ and $\mathbf{x} = \mathbf{0}$ — and (N2) for real scalars, and (N3), all directly from the corresponding axioms for $|||\cdot|||$.

(G1). The letter σ is taken here, so write π for a permutation of $\{1,\dots,p\}$. Extend it to a permutation $\widehat{\pi}$ of $\{1,\dots,m\}$ and to one $\widetilde{\pi}$ of $\{1,\dots,n\}$ by fixing every index greater than p, and let $\mathbf{P} \in M_m(F)$ and $\mathbf{Q} \in M_n(F)$ be their permutation matrices (Definition 2.6.2), which are unitary by Lemma 2.6.6 (b). Writing $\mathbf{D} = \operatorname{diag}_{m,n}(\mathbf{x})$, multiplying by $\mathbf{P}$ on the left moves row k to row $\widehat{\pi}(k)$ and multiplying by $\mathbf{Q}^\top$ on the right moves column l to column $\widetilde{\pi}(l)$; no entry is created or destroyed. The only non-zero entries of $\mathbf{D}$ are $d_{kk} = x_k$ for $k \le p$, and they land in positions $(\widehat{\pi}(k), \widetilde{\pi}(k)) = (\pi(k), \pi(k))$, again on the main diagonal. Hence

$$\mathbf{P}\,\operatorname{diag}_{m,n}(\mathbf{x})\,\mathbf{Q}^\top = \operatorname{diag}_{m,n}(\mathbf{P}_\pi \mathbf{x}).$$

Taking $|||\cdot|||$ of both sides and using Definition 20.4.1 gives $\Phi(\mathbf{P}_\pi\mathbf{x}) = \Phi(\mathbf{x})$.

(G2). Let $\varepsilon_1,\dots,\varepsilon_p$ be signs. The matrix $\operatorname{diag}(\varepsilon_1,\dots,\varepsilon_p,1,\dots,1) \in M_m(F)$ is real diagonal with entries of modulus 1, hence unitary, and multiplying on the left by it multiplies row k by ε_k. So it carries $\operatorname{diag}_{m,n}(\mathbf{x})$ to $\operatorname{diag}_{m,n}(\varepsilon_1 x_1,\dots,\varepsilon_p x_p)$, and invariance gives (G2).

The formula. Let $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$ be a singular value decomposition (Theorem 12.8.1). Then $\mathbf{\Sigma} = \operatorname{diag}_{m,n}(\sigma(\mathbf{A}))$, and $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$ with $\mathbf{U}$ and $\mathbf{V}^*$ unitary, so $|||\mathbf{A}||| = |||\mathbf{\Sigma}||| = \Phi(\sigma(\mathbf{A}))$. This proves the lemma.

■

So the map $|||\cdot||| \mapsto \Phi$ loses nothing. The question is whether it is onto: does every symmetric gauge come from a unitarily invariant norm? Evaluating Φ at $\sigma(\mathbf{A})$ certainly produces a unitarily invariant *function*, by Eq. 20.4.1, and (N1) and (N2) are easy. Everything hangs on the triangle inequality, and the triangle inequality hangs on one majorization.

20.4.3 Singular values are subadditive

Lemma 20.4.2 — Weak Subadditivity of the Singular Values

Let $\mathbf{A}, \mathbf{B} \in M_{m\times n}(F)$. Then

$$\sigma(\mathbf{A}+\mathbf{B}) \prec_w \sigma(\mathbf{A}) + \sigma(\mathbf{B}),$$

that is, $\displaystyle\sum_{i=1}^{k} \sigma_i(\mathbf{A}+\mathbf{B}) \le \sum_{i=1}^{k} \big(\sigma_i(\mathbf{A}) + \sigma_i(\mathbf{B})\big)$ for every $1 \le k \le p$.

Idea. The statement is about singular values, and the tool — Corollary 16.6.5, which says that the top k eigenvalues of a Hermitian sum are subadditive — is about eigenvalues. The Hermitian dilation $\mathcal{H}$ of Proposition 16.9.3 converts one into the other, and it does

so **linearly**: $\mathcal{H}(\mathbf{A}+\mathbf{B}) = \mathcal{H}(\mathbf{A}) + \mathcal{H}(\mathbf{B})$, because the blocks add. Since the top p eigenvalues of $\mathcal{H}(\mathbf{A})$ are exactly $\sigma_1(\mathbf{A}), \dots, \sigma_p(\mathbf{A})$, the corollary transfers verbatim.

Proof. Write $\mathcal{H}(\mathbf{M}) = \left(\begin{smallmatrix} \mathbf{0} & \mathbf{M} \\ \mathbf{M}^* & \mathbf{0} \end{smallmatrix}\right) \in M_{m+n}(F)$ for the Hermitian dilation of Proposition 16.9.3. Adding block by block, $\mathcal{H}(\mathbf{A}+\mathbf{B}) = \mathcal{H}(\mathbf{A}) + \mathcal{H}(\mathbf{B})$.

By Proposition 16.9.3 the eigenvalue list of $\mathcal{H}(\mathbf{M})$, with multiplicity, consists of $\sigma_1(\mathbf{M}), \dots, \sigma_p(\mathbf{M})$, then $m+n-2p$ zeros, then $-\sigma_p(\mathbf{M}), \dots, -\sigma_1(\mathbf{M})$. Every singular value is ≥ 0 and every listed negative number is ≤ 0, so this list, read in the order written, is already decreasing. Hence

$$\lambda_i\big(\mathcal{H}(\mathbf{M})\big) = \sigma_i(\mathbf{M}) \qquad (1 \leq i \leq p),$$

for every $\mathbf{M} \in M_{m\times n}(F)$.

Now fix $1 \leq k \leq p$. The matrices $\mathcal{H}(\mathbf{A})$ and $\mathcal{H}(\mathbf{B})$ are Hermitian of the same size, so Corollary 16.6.5 applies to them:

$$\sum_{i=1}^{k} \lambda_i\big(\mathcal{H}(\mathbf{A}) + \mathcal{H}(\mathbf{B})\big) \;\leq\; \sum_{i=1}^{k} \lambda_i\big(\mathcal{H}(\mathbf{A})\big) + \sum_{i=1}^{k} \lambda_i\big(\mathcal{H}(\mathbf{B})\big).$$

Replacing $\mathcal{H}(\mathbf{A})+\mathcal{H}(\mathbf{B})$ by $\mathcal{H}(\mathbf{A}+\mathbf{B})$ on the left and using the displayed identity three times turns this into

$$\sum_{i=1}^{k} \sigma_i(\mathbf{A}+\mathbf{B}) \;\leq\; \sum_{i=1}^{k} \sigma_i(\mathbf{A}) + \sum_{i=1}^{k} \sigma_i(\mathbf{B}).$$

Finally, $\sigma(\mathbf{A})+\sigma(\mathbf{B})$ is a sum of two decreasing vectors, hence decreasing, so it is its own decreasing rearrangement, and the displayed inequalities for $k = 1, \dots, p$ are precisely (M1) for $\prec_w$ in Definition 16.8.1. This proves the lemma. ∎

Two remarks on the route. The dilation was chosen because it reduces the statement to a corollary already proved, in four lines and with no new variational argument; the alternative is to establish a Ky Fan maximum principle for singular values directly, maximizing $\sum_{i\leq k} |\langle \mathbf{A}\mathbf{w}_i, \mathbf{q}_i\rangle|$ over pairs of orthonormal lists, which is a genuine theorem in its own right and is not needed here. And the conclusion really is only **weak** majorization: for $\mathbf{A} = \mathbf{I}_2$ and $\mathbf{B} = \operatorname{diag}(-1, 1)$ we have $\sigma(\mathbf{A}) = \sigma(\mathbf{B}) = (1, 1)$ and $\mathbf{A}+\mathbf{B} = \operatorname{diag}(0, 2)$, so $\sigma(\mathbf{A}+\mathbf{B}) = (2, 0)$ has total 2 while $\sigma(\mathbf{A}) + \sigma(\mathbf{B}) = (2, 2)$ has total 4. Section 6 records this as a negative result: no strengthening to $\prec$ is available.

The debts of the last two examples are now paid. By Lemma 20.4.2 with k fixed,

$$\|\mathbf{A}+\mathbf{B}\|_{(k)} \;\leq\; \|\mathbf{A}\|_{(k)} + \|\mathbf{B}\|_{(k)},$$

so the Ky Fan k-norms of Definition 20.4.2 really are norms, and so is the trace norm, the case $k = p$. Chapter 16 §06's Ky Fan functionals have been repaired exactly as that section promised.

20.4.4 The correspondence

Theorem 20.4.3 — Unitarily Invariant Norms Are Symmetric Gauges

Let $m, n \geq 1$ and $p = \min(m, n)$. The assignments

$$\|\cdot\| \longmapsto \Phi_{\|\cdot\|}(\mathbf{x}) = \left\|\operatorname{diag}_{m,n}(\mathbf{x})\right\|, \qquad \Phi \longmapsto \|\mathbf{A}\|_\Phi = \Phi\big(\sigma(\mathbf{A})\big)$$

are mutually inverse bijections between the unitarily invariant norms on $M_{m\times n}(F)$ and the symmetric gauge functions on $\mathbb{R}^p$.

Idea. Lemma 20.4.1 is one direction and already contains the fact that the round trip $\|\cdot\| \mapsto \Phi \mapsto \|\cdot\|$ is the identity. For the other direction the only issue is the triangle inequality for $\mathbf{A} \mapsto \Phi(\sigma(\mathbf{A}))$, and it splits into two steps that have just been prepared: $\sigma(\mathbf{A}+\mathbf{B}) \prec_w \sigma(\mathbf{A})+\sigma(\mathbf{B})$, then §03's theorem, then the triangle inequality for Φ itself.

Proof. **Step 1: $\|\cdot\|_\Phi$ is a unitarily invariant norm.** Let Φ be a symmetric gauge function on $\mathbb{R}^p$ and put $\|\mathbf{A}\|_\Phi = \Phi(\sigma(\mathbf{A}))$.

(N1). $\Phi(\sigma(\mathbf{A})) \geq 0$, and it vanishes only if $\sigma(\mathbf{A}) = \mathbf{0}$, which by Theorem 12.8.1 forces $\mathbf{A} = \mathbf{U0V}^* = \mathbf{0}$.

(N2). For $c \in F$, $(c\mathbf{A})^*(c\mathbf{A}) = |c|^2\mathbf{A}^*\mathbf{A}$, so each eigenvalue of $(c\mathbf{A})^*(c\mathbf{A})$ is $|c|^2$ times the matching eigenvalue of $\mathbf{A}^*\mathbf{A}$ and Definition 12.8.1 gives $\sigma(c\mathbf{A}) = |c|\sigma(\mathbf{A})$. Hence $\|c\mathbf{A}\|_\Phi = \Phi(|c|\sigma(\mathbf{A})) = |c|\,\|\mathbf{A}\|_\Phi$.

(N3). The vectors $\sigma(\mathbf{A}+\mathbf{B})$ and $\sigma(\mathbf{A})+\sigma(\mathbf{B})$ have non-negative entries, and Lemma 20.4.2 gives $\sigma(\mathbf{A}+\mathbf{B}) \prec_w \sigma(\mathbf{A})+\sigma(\mathbf{B})$. So Theorem 20.3.4 (b) applies, and then the triangle inequality for the norm Φ:

$$\begin{aligned}\|\mathbf{A}+\mathbf{B}\|_\Phi = \Phi\big(\sigma(\mathbf{A}+\mathbf{B})\big) &\leq \Phi\big(\sigma(\mathbf{A})+\sigma(\mathbf{B})\big)\\ &\leq \Phi\big(\sigma(\mathbf{A})\big)+\Phi\big(\sigma(\mathbf{B})\big) = \|\mathbf{A}\|_\Phi + \|\mathbf{B}\|_\Phi .\end{aligned}$$

Invariance. By Eq. 20.4.1, $\sigma(\mathbf{UAV}) = \sigma(\mathbf{A})$ for unitary $\mathbf{U}, \mathbf{V}$, so $\|\mathbf{UAV}\|_\Phi = \|\mathbf{A}\|_\Phi$.

Step 2: the round trips. Start from a unitarily invariant norm $\|\cdot\|$. By Lemma 20.4.1 its $\Phi = \Phi_{\|\cdot\|}$ is a symmetric gauge and $\|\mathbf{A}\| = \Phi(\sigma(\mathbf{A})) = \|\mathbf{A}\|_\Phi$ for every $\mathbf{A}$, so the second assignment undoes the first.

Start instead from a symmetric gauge Φ on $\mathbb{R}^p$, and let Ψ be the gauge of the norm $\|\cdot\|_\Phi$. For $\mathbf{x} \in \mathbb{R}^p$, the matrix $\operatorname{diag}_{m,n}(\mathbf{x})$ has $\operatorname{diag}_{m,n}(\mathbf{x})^* \operatorname{diag}_{m,n}(\mathbf{x}) = \operatorname{diag}(x_1^2, \ldots, x_p^2, 0, \ldots, 0)$, whose eigenvalue list in decreasing order is $(|\mathbf{x}|^\downarrow)^2$ padded with zeros; so Definition 12.8.1 gives $\sigma(\operatorname{diag}_{m,n}(\mathbf{x})) = |\mathbf{x}|^\downarrow$. Hence

$$\Psi(\mathbf{x}) = \left\|\operatorname{diag}_{m,n}(\mathbf{x})\right\|_\Phi = \Phi\big(|\mathbf{x}|^\downarrow\big) = \Phi(\mathbf{x}),$$

the last equality by Eq. 20.3.1. So the first assignment undoes the second, and the two maps are mutually inverse bijections. This proves the theorem. ∎

The theorem is a machine for producing matrix norms: choose any symmetric gauge and it hands back a unitarily invariant norm, with the triangle inequality free of charge. Feeding it the gauges of Example (The p-norms, the Ky Fan gauges, and size one) (a) gives the most-used

family.

Example. (The Schatten norms)

The letter p is reserved in this section for $\min(m,n)$, so write the exponent as r. For $1 \le r \le \infty$, the **Schatten r-norm** is

$$\|\mathbf{A}\|_{S_r} = \|\sigma(\mathbf{A})\|_r = \Big(\sum_{i=1}^{p} \sigma_i(\mathbf{A})^r\Big)^{1/r},$$

read as $\|\mathbf{A}\|_{S_\infty} = \sigma_1(\mathbf{A})$ at $r = \infty$. Identify S_1, S_2 and S_∞, and explain why each $\|\cdot\|_{S_r}$ is a unitarily invariant norm.

Solution. By Example (The p-norms, the Ky Fan gauges, and size one) (a), $\|\cdot\|_r$ is a symmetric gauge function on $\mathbb{R}^p$ for every $1 \le r \le \infty$. So Theorem 20.4.3 makes $\mathbf{A} \mapsto \|\sigma(\mathbf{A})\|_r$ a unitarily invariant norm, with no further checking. At the three familiar exponents: $\|\cdot\|_{S_1}$ is the trace norm, since $\|\sigma(\mathbf{A})\|_1 = \sum_i \sigma_i(\mathbf{A})$; $\|\cdot\|_{S_2}$ is the Frobenius norm, since $\|\mathbf{A}\|_F^2 = \|\mathbf{\Sigma}\|_F^2 = \sum_i \sigma_i(\mathbf{A})^2$ by Lemma 11.11.1 applied to $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$; and $\|\cdot\|_{S_\infty}$ is the spectral norm, by Theorem 15.3.3 (c). The three norms Chapter 15 measured matrices with are three points of one family. A concrete reading: the symmetric $\mathbf{A} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ has eigenvalues 3 and 1, both positive, so $\mathbf{A}^*\mathbf{A} = \mathbf{A}^2$ has eigenvalues 9 and 1 and $\sigma(\mathbf{A}) = (3,1)$ by Definition 12.8.1. Hence $\|\mathbf{A}\|_{S_1} = 4$, $\|\mathbf{A}\|_{S_2} = \sqrt{10}$ — which matches $\|\mathbf{A}\|_F = \sqrt{4+1+1+4}$ — and $\|\mathbf{A}\|_{S_\infty} = 3$.

20.4.5 What every unitarily invariant norm satisfies

Chapter 19 §09 collected the facts it needed about moving factors in and out of the spectral and Frobenius norms (Lemma 19.9.1). Part (b) of that lemma — $\|\mathbf{XMY}\| \le \|\mathbf{X}\|_2 \|\mathbf{M}\| \|\mathbf{Y}\|_2$ — was proved separately for the two norms. It holds for all of them at once.

Proposition 20.4.4 — Basic Properties

Let $\|\cdot\|$ be a unitarily invariant norm on $M_{m\times n}(F)$, with gauge Φ as in Lemma 20.4.1, and let $\mathbf{A} \in M_{m\times n}(F)$.

(a) $\sigma(\mathbf{A}^*) = \sigma(\mathbf{A})$; consequently, if $\|\cdot\|'$ is the unitarily invariant norm on $M_{n\times m}(F)$ attached to the same gauge Φ by Theorem 20.4.3, then $\|\mathbf{A}^*\|' = \|\mathbf{A}\|$. For $m = n$ this reads $\|\mathbf{A}^*\| = \|\mathbf{A}\|$.

(b) $\|\mathbf{XA}\| \le \|\mathbf{X}\|_2 \, \|\mathbf{A}\|$ for every $\mathbf{X} \in M_m(F)$, and $\|\mathbf{AY}\| \le \|\mathbf{A}\| \, \|\mathbf{Y}\|_2$ for every $\mathbf{Y} \in M_n(F)$.

(c) If $\|\cdot\|$ is **normalized**, meaning $\|\mathbf{e}_1\mathbf{e}_1^*\| = 1$ for the $m \times n$ matrix $\mathbf{e}_1\mathbf{e}_1^*$ with a single 1 in position $(1,1)$, then

$$\|\mathbf{A}\|_2 \;\le\; \|\mathbf{A}\| \;\le\; \|\mathbf{A}\|_{(p)}\,.$$

(d) A normalized unitarily invariant norm on $M_n(F)$ is submultiplicative: $\|\mathbf{AB}\| \le$

$|||\mathbf{A}||| \, |||\mathbf{B}|||$.

Idea. Everything reduces to one inequality between singular values, $\sigma_i(\mathbf{XA}) \le \|\mathbf{X}\|_2 \sigma_i(\mathbf{A})$, and then to §03's monotonicity Proposition 20.3.1. That inequality is one line of the min–max theorem: the subspace on which $\mathbf{A}$ stretches by at most $\sigma_i(\mathbf{A})$ also works for $\mathbf{XA}$, with the factor $\|\mathbf{X}\|_2$ paid once. Part (c) is Corollary 20.3.2, read through the correspondence, and (d) is (b) and (c) combined.

Proof.

(a) By Theorem 12.8.1 write $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$; then $\mathbf{A}^* = \mathbf{V}\mathbf{\Sigma}^*\mathbf{U}^*$, and $\mathbf{\Sigma}^* = \operatorname{diag}_{n,m}(\sigma(\mathbf{A}))$ has the same diagonal. By Theorem 12.8.2 applied to $\mathbf{A}^*$, $\sigma(\mathbf{A}^*) = \sigma(\mathbf{A})$. The consequence is Lemma 20.4.1 used twice: $|||\mathbf{A}^*|||' = \Phi(\sigma(\mathbf{A}^*)) = \Phi(\sigma(\mathbf{A})) = |||\mathbf{A}|||$.

(b) Everything rests on one inequality between singular values.

> *Claim.* $\sigma_k(\mathbf{XA}) \le \|\mathbf{X}\|_2 \, \sigma_k(\mathbf{A})$ for every $1 \le k \le n$, with the convention $\sigma_k = 0$ for $k > p$.
>
> *Proof.* Fix a singular value decomposition of $\mathbf{A}$ with right singular vectors $\mathbf{v}_1, \dots, \mathbf{v}_n$, and let $T_k = \operatorname{span}(\mathbf{v}_k, \dots, \mathbf{v}_n)$, a subspace of F^n of dimension $n - k + 1$. By Lemma 16.9.1 (a), $\|\mathbf{Ax}\| \le \sigma_k(\mathbf{A})\|\mathbf{x}\|$ for every $\mathbf{x} \in T_k$. By Theorem 15.3.2 (a), $\|\mathbf{X}(\mathbf{Ax})\| \le \|\mathbf{X}\|_2 \|\mathbf{Ax}\|$, so
>
> $$\|(\mathbf{XA})\mathbf{x}\| \le \|\mathbf{X}\|_2 \, \sigma_k(\mathbf{A}) \, \|\mathbf{x}\| \qquad (\mathbf{x} \in T_k).$$
>
> The matrices $\mathbf{XA}$ and $\mathbf{A}$ both have n columns, so Theorem 16.9.2 applies to $\mathbf{XA}$ with subspaces of F^n: $\sigma_k(\mathbf{XA})$ is the **minimum** over subspaces of dimension $n-k+1$ of the largest stretch on them, and T_k is one competitor. Hence $\sigma_k(\mathbf{XA}) \le \|\mathbf{X}\|_2 \sigma_k(\mathbf{A})$.
>
> ■

Now $\mathbf{XA}$ and $\mathbf{A}$ lie in the same space $M_{m\times n}(F)$, and the claim says $|\sigma_i(\mathbf{XA})| \le |\|\mathbf{X}\|_2 \sigma_i(\mathbf{A})|$ for $1 \le i \le p$. By Proposition 20.3.1 and then (N2) for Φ,

$$|||\mathbf{XA}||| = \Phi\big(\sigma(\mathbf{XA})\big) \le \Phi\big(\|\mathbf{X}\|_2 \sigma(\mathbf{A})\big) = \|\mathbf{X}\|_2 \, \Phi\big(\sigma(\mathbf{A})\big) = \|\mathbf{X}\|_2 \, |||\mathbf{A}||| \, .$$

For the second inequality, apply the first to $\mathbf{A}^*$ and $\mathbf{Y}^*$ inside $M_{n\times m}(F)$, with the norm $|||\cdot|||'$ of part (a): $|||(\mathbf{AY})^*|||' = |||\mathbf{Y}^*\mathbf{A}^*|||' \le \|\mathbf{Y}^*\|_2 \, |||\mathbf{A}^*|||'$. By (a) the left side is $|||\mathbf{AY}|||$ and $|||\mathbf{A}^*|||' = |||\mathbf{A}|||$, while $\|\mathbf{Y}^*\|_2 = \|\mathbf{Y}\|_2$ by Lemma 19.9.1 (a).

(c) The matrix $\mathbf{e}_1\mathbf{e}_1^*$ is $\operatorname{diag}_{m,n}(\mathbf{e}_1)$, so the normalization says $\Phi(\mathbf{e}_1) = 1$. By Corollary 20.3.2, $\Phi(\mathbf{e}_1)\|\mathbf{x}\|_\infty \le \Phi(\mathbf{x}) \le \Phi(\mathbf{e}_1)\|\mathbf{x}\|_1$ for every $\mathbf{x} \in \mathbb{R}^p$. At $\mathbf{x} = \sigma(\mathbf{A})$ this reads

$$\sigma_1(\mathbf{A}) \;\le\; \Phi\big(\sigma(\mathbf{A})\big) \;\le\; \sum_{i=1}^{p} \sigma_i(\mathbf{A}),$$

which is the claim, since $\sigma_1(\mathbf{A}) = \|\mathbf{A}\|_2$ by Theorem 15.3.3 (c) and the right-hand side is $|||\mathbf{A}|||_{(p)}$ by Definition 20.4.2.

(d) By (b) and then (c), $|||\mathbf{AB}||| \le \|\mathbf{A}\|_2 \, |||\mathbf{B}||| \le |||\mathbf{A}||| \, |||\mathbf{B}|||$. This proves the proposition.

■

Applying (b) twice, once on each side, gives $\|\mathbf{XAY}\| \le \|\mathbf{X}\|_2 \, \|\mathbf{A}\| \, \|\mathbf{Y}\|_2$. That is Lemma 19.9.1 (b) with the two named norms replaced by any unitarily invariant one, so the debt announced at the head of this subsection is paid. Taking $\mathbf{X} = \mathbf{U}$ and $\mathbf{Y} = \mathbf{V}$ unitary recovers Definition 20.4.1 itself: a unitary matrix has orthonormal columns, so $\|\mathbf{U}\|_2 = \|\mathbf{V}\|_2 = 1$ by Lemma 19.9.1 (c), and the bound reads $\|\mathbf{UAV}\| \le \|\mathbf{A}\|$; applying it again to $\mathbf{U}^*(\mathbf{UAV})\mathbf{V}^* = \mathbf{A}$ gives $\|\mathbf{A}\| \le \|\mathbf{UAV}\|$, and the two together give equality.

> *Warning.* **A unitarily invariant norm need not be submultiplicative, and the normalization in (d) is what supplies the lower bound that rules it out.** Half the spectral norm, $\|\mathbf{A}\| = \frac{1}{2}\|\mathbf{A}\|_2$, is a unitarily invariant norm — it is $\Phi(\sigma(\mathbf{A}))$ for the symmetric gauge $\Phi = \frac{1}{2}\|\cdot\|_\infty$. At $\mathbf{A} = \mathbf{B} = \mathbf{I}_n$ it gives $\|\mathbf{AB}\| = \frac{1}{2}$ while $\|\mathbf{A}\| \, \|\mathbf{B}\| = \frac{1}{4}$, so submultiplicativity fails. Doubling instead of halving is harmless: $2\|\cdot\|_2$ is submultiplicative. What Proposition 20.4.4 (d) really needs is $\|\mathbf{A}\|_2 \le \|\mathbf{A}\|$, and Corollary 20.3.2 delivers that as soon as $\|\mathbf{e}_1\mathbf{e}_1^*\| \ge 1$, normalized or not; here $\|\mathbf{e}_1\mathbf{e}_1^*\| = \frac{1}{2}$, and the bound runs the wrong way. Submultiplicativity is a property of the **scaling** of a norm, not of its shape.

Theorem 20.4.3 is the section's payment of Chapter 15 §08's debt: the norms invariant under unitary multiplication are exactly the symmetric gauges of the singular values, and there are as many of them as there are norms on $\mathbb{R}^p$ that ignore order and sign. What the correspondence buys is that any inequality between two singular value lists in the weak majorization order becomes an inequality between the matrices in **every** one of these norms at once. Section 6 makes that the definition of dominance and uses it to settle low-rank approximation and the nearest unitary matrix; Section 7 does the same for Lidskii's and Mirsky's theorems.

20.4.6 Exercises

20.4.6.1 A. Check your understanding

Exercise A1.

(a) State Definition 20.4.1, saying exactly which matrices $\mathbf{U}$ and $\mathbf{V}$ range over.

(b) Explain in one sentence why a unitarily invariant norm can be computed from $\sigma(\mathbf{A})$ alone.

(c) True or false, with a reason: $\mathbf{A} \mapsto \max_{i,j}|a_{ij}|$ is a unitarily invariant norm on $M_2(\mathbb{R})$.

(d) Which axiom of Definition 15.1.1 is the only hard one for $\mathbf{A} \mapsto \Phi(\sigma(\mathbf{A}))$, and which two earlier results prove it?

Solution.

(a) A norm $\|\cdot\|$ on $M_{m\times n}(F)$ with $\|\mathbf{UAV}\| = \|\mathbf{A}\|$ for every $\mathbf{A}$ and all unitary $\mathbf{U} \in M_m(F)$ and $\mathbf{V} \in M_n(F)$, the two chosen independently.

(b) Because $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$ with $\mathbf{\Sigma} = \operatorname{diag}_{m,n}(\sigma(\mathbf{A}))$, so invariance gives $\|\mathbf{A}\| = \|\mathbf{\Sigma}\|$, a quantity built from $\sigma(\mathbf{A})$ alone (Lemma 20.4.1).

(c) False. It is a norm but not unitarily invariant: $\mathbf{I}_2$ and the rotation $\mathbf{U} = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ have entrywise maxima 1 and $1/\sqrt{2}$, while $\mathbf{U} = \mathbf{U}\mathbf{I}_2\mathbf{I}_2$.

(d) The triangle inequality (N3). It follows from Lemma 20.4.2, which gives $\sigma(\mathbf{A} +$

$\mathbf{B}) \prec_w \sigma(\mathbf{A}) + \sigma(\mathbf{B})$, together with Theorem 20.3.4 (b), which turns a weak majorization of non-negative vectors into an inequality of gauges.

20.4.6.2 B. Practice

Exercise B1: Which of these are unitarily invariant norms.

Determine which of the following are unitarily invariant norms on $M_2(\mathbb{R})$. Justify your answer, naming the clause that fails when one does.

(a) $|||\mathbf{A}||| = \sigma_1(\mathbf{A}) + \sigma_2(\mathbf{A})$.
(b) $|||\mathbf{A}||| = |a_{11}| + |a_{12}| + |a_{21}| + |a_{22}|$.
(c) $|||\mathbf{A}||| = \big(\sigma_1(\mathbf{A})^3 + \sigma_2(\mathbf{A})^3\big)^{1/3}$.
(d) $|||\mathbf{A}||| = |\operatorname{tr}\mathbf{A}|$.
(e) $|||\mathbf{A}||| = \max\big(\sigma_1(\mathbf{A}),\ 2\sigma_2(\mathbf{A})\big)$.

Solution.

(a) Yes: this is the trace norm, the Ky Fan 2-norm of Definition 20.4.2, equivalently $|||\cdot|||_{S_1}$ of Example (The Schatten norms). Alternatively, it is $\Phi(\sigma(\mathbf{A}))$ for $\Phi = \|\cdot\|_1$, so Theorem 20.4.3 applies.

(b) No. It is a norm — the 1-norm of the entry list — but it is not unitarily invariant: it gives $\mathbf{I}_2$ the value 2 and the rotation $\mathbf{U}$ above the value $4/\sqrt{2} = 2\sqrt{2}$, although $\sigma(\mathbf{I}_2) = \sigma(\mathbf{U}) = (1, 1)$.

(c) Yes: it is $\Phi(\sigma(\mathbf{A}))$ for $\Phi = \|\cdot\|_3$, a symmetric gauge by Example (The p-norms, the Ky Fan gauges, and size one) (a), so Theorem 20.4.3 applies. This is the Schatten 3-norm.

(d) No. It is unitarily *similarity* invariant but not a norm: $\operatorname{tr}\left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right) = 0$ with the matrix non-zero, so (N1) fails. It is not unitarily invariant either, since $\operatorname{tr}(\mathbf{UAV})$ generally differs from $\operatorname{tr}\mathbf{A}$.

(e) No. By Theorem 20.4.3 the question is whether $\Phi(\mathbf{x}) = \max(|x|_1^{\downarrow},\ 2|x|_2^{\downarrow})$ is a symmetric gauge on $\mathbb{R}^2$, and it is not a norm: subadditivity fails. Take $\mathbf{x} = (1, \frac{1}{2})$ and $\mathbf{y} = (\frac{1}{2}, 1)$. Then $\Phi(\mathbf{x}) = \max(1, 1) = 1$ and $\Phi(\mathbf{y}) = 1$, while $\mathbf{x} + \mathbf{y} = (\frac{3}{2}, \frac{3}{2})$ gives $\Phi(\mathbf{x} + \mathbf{y}) = \max(\frac{3}{2}, 3) = 3 > 2$. The failure is easy to see in the matrices as well: $\operatorname{diag}(1, \frac{1}{2})$ and $\operatorname{diag}(\frac{1}{2}, 1)$ each get the value 1, and their sum $\frac{3}{2}\mathbf{I}_2$ gets 3. The trap is that $\mathbf{x} \mapsto 2|x|_2^{\downarrow}$ is not a norm — it vanishes at $\mathbf{e}_1$ — so the maximum of it with Φ_1 inherits nothing. Contrast exercise C1 below, where both members of the maximum are norms.

Exercise B2: Measuring one matrix in every way.

Let

$$\mathbf{A} = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}.$$

(a) Compute $\sigma(\mathbf{A})$ and $\sigma(\mathbf{B})$, and then $\|\mathbf{A}\|_2$, $\|\mathbf{A}\|_F$, $|||\mathbf{A}|||_{(1)}$ and $|||\mathbf{A}|||_{(2)}$.
(b) Compute $\sigma(\mathbf{A} + \mathbf{B})$ and verify $\sigma(\mathbf{A} + \mathbf{B}) \prec_w \sigma(\mathbf{A}) + \sigma(\mathbf{B})$ directly, saying for which k the inequality is strict.

(c) Verify Proposition 20.4.4 (c) for $\mathbf{A}$ and the Frobenius norm, and check that the Frobenius norm is normalized.

Solution.

(a) $\mathbf{A}$ is real symmetric with eigenvectors $(1,1)$ and $(1,-1)$ for the eigenvalues 3 and 1. Hence $\mathbf{A}^*\mathbf{A} = \mathbf{A}^2$ has eigenvalues 9 and 1, and Definition 12.8.1 gives $\sigma(\mathbf{A}) = (3,1)$, as in Example (The Schatten norms). Likewise $\mathbf{B}$ has eigenvectors $(1,-1)$ and $(1,1)$ for 3 and 1, so $\sigma(\mathbf{B}) = (3,1)$. Hence $\|\mathbf{A}\|_2 = 3$, $\|\mathbf{A}\|_F = \sqrt{9+1} = \sqrt{10}$ (which agrees with $\sqrt{4+1+1+4}$), $|||\mathbf{A}|||_{(1)} = 3$ and $|||\mathbf{A}|||_{(2)} = 4$.

(b) $\mathbf{A}+\mathbf{B} = \operatorname{diag}(4,4)$, so $\sigma(\mathbf{A}+\mathbf{B}) = (4,4)$, while $\sigma(\mathbf{A}) + \sigma(\mathbf{B}) = (6,2)$. The partial sums are $4, 8$ against $6, 8$: strict at $k=1$, equality at $k=2$. So $\sigma(\mathbf{A}+\mathbf{B}) \prec_w \sigma(\mathbf{A}) + \sigma(\mathbf{B})$, and here the totals happen to agree, so the relation is even a majorization.

(c) The Frobenius norm has $\|\mathbf{e}_1\mathbf{e}_1^\top\|_F = 1$, so it is normalized. The chain reads $3 = \|\mathbf{A}\|_2 \le \sqrt{10} \le 4 = |||\mathbf{A}|||_{(2)}$, and $9 \le 10 \le 16$ confirms it.

Exercise B3: Moving a factor across.

Let $\mathbf{A} \in M_{m\times n}(F)$, let $|||\cdot|||$ be a unitarily invariant norm on $M_{m\times n}(F)$, and let P be an orthogonal projection of F^m onto a subspace, with matrix $\mathbf{P}$.

(a) Prove that $\|\mathbf{P}\|_2 \le 1$.

(b) Deduce that $|||\mathbf{PA}||| \le |||\mathbf{A}|||$.

(c) Give an example with $m = n = 2$ in which the inequality in (b) is strict for the Frobenius norm.

Solution.

(a) For $\mathbf{x} \in F^m$, write $\mathbf{x} = \mathbf{Px} + (\mathbf{x} - \mathbf{Px})$, an orthogonal decomposition, so $\|\mathbf{x}\|^2 = \|\mathbf{Px}\|^2 + \|\mathbf{x}-\mathbf{Px}\|^2 \ge \|\mathbf{Px}\|^2$ by Theorem 10.1.3. Hence $\|\mathbf{Px}\| \le \|\mathbf{x}\|$ for every $\mathbf{x}$, and $\|\mathbf{P}\|_2 \le 1$ by Definition 15.3.2.

(b) By Proposition 20.4.4 (b) with $\mathbf{X} = \mathbf{P}$, $|||\mathbf{PA}||| \le \|\mathbf{P}\|_2\,|||\mathbf{A}||| \le |||\mathbf{A}|||$.

(c) Take $\mathbf{P} = \mathbf{e}_1\mathbf{e}_1^\top$ and $\mathbf{A} = \mathbf{I}_2$. Then $\mathbf{PA} = \mathbf{e}_1\mathbf{e}_1^\top$ has $\|\mathbf{PA}\|_F = 1$, while $\|\mathbf{I}_2\|_F = \sqrt{2}$.

20.4.6.3 C. Going deeper

Exercise C1: A gauge built from two Ky Fan gauges.

On $\mathbb{R}^p$ let $\Phi(\mathbf{x}) = \max\big(\Phi_1(\mathbf{x}),\ \tfrac{2}{k}\Phi_k(\mathbf{x})\big)$ for a fixed $2 \le k \le p$, with Φ_1 and Φ_k the Ky Fan gauges of Definition 20.3.2.

(a) Prove that Φ is a symmetric gauge function.

(b) Write down the unitarily invariant norm it induces on $M_{m\times n}(F)$, and decide whether it is normalized.

(c) For $p = k = 2$, show that $\Phi(\mathbf{x}) = \max(|x|^{\downarrow}_1,\ |x_1|+|x_2|) = |x_1|+|x_2|$, and conclude that the norm of (b) is the trace norm in that case.

Solution.

(a) A maximum of finitely many norms is a norm: it is non-negative, absolutely homogeneous and subadditive because each member is, and it vanishes only where all members do, hence only at $\mathbf{0}$. Here both members are symmetric gauges by Example (The p-norms, the Ky Fan gauges, and size one) (b), and a maximum of permutation invariant and sign invariant functions has the same invariances. So Φ satisfies Definition 20.3.1.

(b) By Theorem 20.4.3 the induced norm is

$$|||\mathbf{A}||| = \max\Big(\sigma_1(\mathbf{A}),\ \tfrac{2}{k}\sum_{i\le k}\sigma_i(\mathbf{A})\Big).$$

It is normalized: at $\mathbf{A} = \mathbf{e}_1\mathbf{e}_1^*$ the singular values are $1, 0, \dots, 0$, so the two candidates are 1 and $2/k \le 1$, and the maximum is 1.

(c) With $p = k = 2$, $\frac{2}{2}\Phi_2(\mathbf{x}) = |x_1| + |x_2|$, which is at least $\Phi_1(\mathbf{x}) = |x|_1^{\downarrow}$. So $\Phi = \|\cdot\|_1$, and the induced norm is $\sigma_1(\mathbf{A}) + \sigma_2(\mathbf{A})$, the trace norm.

Exercise C2: How much scaling submultiplicativity can stand.

Let $c > 0$ and consider $N_c(\mathbf{A}) = c\,\|\mathbf{A}\|_2$ on $M_n(F)$, $n \ge 1$.

(a) Prove that N_c is a unitarily invariant norm for every $c > 0$, and compute its gauge.

(b) Determine exactly which c make N_c submultiplicative. *Hint: test at* $\mathbf{A} = \mathbf{B} = \mathbf{I}_n$.

(c) Do the same for $M_c(\mathbf{A}) = c\,|||\mathbf{A}|||_{(n)}$, the scaled trace norm. Show that $\mathbf{A} = \mathbf{B} = \mathbf{I}_n$ is now the **wrong** test matrix, and find one that gives the sharp answer.

Solution.

(a) A positive multiple of a norm is a norm, and multiplying by c does not disturb $N_c(\mathbf{UAV}) = N_c(\mathbf{A})$. Its gauge is $\mathbf{x} \mapsto N_c(\mathrm{diag}(\mathbf{x})) = c\|\mathbf{x}\|_\infty$, since the largest singular value of $\mathrm{diag}(\mathbf{x})$ is $\|\mathbf{x}\|_\infty$.

(b) Exactly $c \ge 1$. If $c \ge 1$, then $N_c(\mathbf{AB}) = c\|\mathbf{AB}\|_2 \le c\|\mathbf{A}\|_2\|\mathbf{B}\|_2 \le c^2\|\mathbf{A}\|_2\|\mathbf{B}\|_2 = N_c(\mathbf{A})N_c(\mathbf{B})$, using submultiplicativity of the spectral norm (Theorem 15.3.2 (d)) and $c \le c^2$. If $c < 1$, take $\mathbf{A} = \mathbf{B} = \mathbf{I}_n$: then $N_c(\mathbf{AB}) = c$ while $N_c(\mathbf{A})N_c(\mathbf{B}) = c^2 < c$.

(c) The answer is again exactly $c \ge 1$. Sufficiency: by Proposition 20.4.4 (b) and (c), $|||\mathbf{AB}|||_{(n)} \le \|\mathbf{A}\|_2\,|||\mathbf{B}|||_{(n)} \le |||\mathbf{A}|||_{(n)}\,|||\mathbf{B}|||_{(n)}$, so for $c \ge 1$,

$$M_c(\mathbf{AB}) = c\,|||\mathbf{AB}|||_{(n)} \le c\,|||\mathbf{A}|||_{(n)}\,|||\mathbf{B}|||_{(n)} \le c^2\,|||\mathbf{A}|||_{(n)}\,|||\mathbf{B}|||_{(n)} = M_c(\mathbf{A})M_c(\mathbf{B}).$$

Necessity: at $\mathbf{A} = \mathbf{B} = \mathbf{I}_n$ one gets $M_c(\mathbf{I}_n) = cn$ and the requirement $cn \le c^2n^2$, that is $c \ge 1/n$ — a weaker condition, so for $n \ge 2$ the identity is the wrong test matrix. Take instead $\mathbf{A} = \mathbf{B} = \mathbf{e}_1\mathbf{e}_1^{\top}$, which is idempotent with singular values $1, 0, \dots, 0$. Then $M_c(\mathbf{AB}) = c$ while $M_c(\mathbf{A})M_c(\mathbf{B}) = c^2$, and $c \le c^2$ forces $c \ge 1$. The moral: submultiplicativity is tested by matrices of the **smallest** rank, where the trace norm and the spectral norm agree, not by the identity, where they differ by a factor of n.

Exercise C3: The correspondence in the smallest case.

(a) Describe all unitarily invariant norms on $M_{1\times n}(F)$, the row vectors. *Hint: what is p?*

(b) Deduce that on $M_{1\times n}(F)$ every unitarily invariant norm is a positive multiple of the Euclidean norm of the row.

(c) Explain why the answer to (a) does not contradict the existence of many different unitarily invariant norms on $M_2(F)$.

Solution.

(a) Here $p = \min(1, n) = 1$, so Theorem 20.4.3 matches unitarily invariant norms on $M_{1\times n}(F)$ with symmetric gauge functions on $\mathbb{R}^1$. By Example (The p-norms, the Ky Fan gauges, and size one) (c), every norm on $\mathbb{R}^1$ is such a gauge, and each is $\Phi(t) = c|t|$ with $c > 0$. So the unitarily invariant norms are exactly $\mathbf{A} \mapsto c\,\sigma_1(\mathbf{A})$, $c > 0$.

(b) A row vector $\mathbf{a}^\top$ has $\mathbf{A}^*\mathbf{A} = \bar{\mathbf{a}}\mathbf{a}^\top$ of rank at most 1, with the single non-zero eigenvalue $\mathbf{a}^*\mathbf{a} = \|\mathbf{a}\|_2^2$; so $\sigma_1(\mathbf{A}) = \|\mathbf{a}\|_2$. Hence every unitarily invariant norm on $M_{1\times n}(F)$ is $c\|\mathbf{a}\|_2$.

(c) Because the correspondence is with norms on $\mathbb{R}^p$, and $p = 1$ leaves only one shape. For $M_2(F)$, $p = 2$, and there are many norms on $\mathbb{R}^2$ that are permutation and sign invariant — the whole family $\|\cdot\|_q$ for $1 \le q \le \infty$, for instance, giving the Schatten norms of Example (The Schatten norms). The rigidity in (a) is a statement about $\mathbb{R}^1$, not about matrices.

20.5 The Trace Inequality

Sections 3 and 4 built a dictionary: a unitarily invariant norm is a symmetric gauge applied to the list of singular values, and a symmetric gauge respects weak majorization. To use that dictionary we need a supply of inequalities between singular values, and the cleanest source of them is a single scalar inequality about how two matrices pair against each other. This section proves it. The pairing is the Frobenius one, $\operatorname{tr}(\mathbf{A}^*\mathbf{B})$, and the theorem says that it is largest when the two matrices are *aligned*: when their singular value decompositions can be written with the same unitary factors.

20.5.1 How large can a pairing be?

Chapter 10 §01 made $M_{m\times n}(F)$ an inner product space with $\langle \mathbf{A}, \mathbf{B}\rangle = \operatorname{tr}(\mathbf{B}^*\mathbf{A})$, whose norm is the Frobenius norm $\|\mathbf{A}\|_F$. So $\operatorname{tr}(\mathbf{A}^*\mathbf{B}) = \langle \mathbf{B}, \mathbf{A}\rangle$ is an inner product of two matrices, and Cauchy–Schwarz (Theorem 10.1.5) already bounds it:

$$|\operatorname{tr}(\mathbf{A}^*\mathbf{B})| \;\le\; \|\mathbf{A}\|_F\,\|\mathbf{B}\|_F = \Big(\sum_i \sigma_i(\mathbf{A})^2\Big)^{1/2}\Big(\sum_i \sigma_i(\mathbf{B})^2\Big)^{1/2},$$

using $\|\mathbf{A}\|_F^2 = \sum_i \sigma_i(\mathbf{A})^2$. That bound depends only on the two lists of singular values, which is the right kind of answer; but it is not the best one.

Here is the smallest example. Let $\mathbf{A} = \operatorname{diag}(2,1)$ and $\mathbf{B} = \mathbf{I}_2$. Then $\operatorname{tr}(\mathbf{A}^*\mathbf{B}) = 3$, while Cauchy–Schwarz allows $\sqrt{5}\cdot\sqrt{2} \approx 3.162$. The number 3 is $\sigma_1(\mathbf{A})\sigma_1(\mathbf{B}) + \sigma_2(\mathbf{A})\sigma_2(\mathbf{B})$, the two lists of singular values multiplied **term by term in decreasing order**. That is the true bound, and the pairing $\sum_i \sigma_i\tau_i$ is never larger than the Cauchy–Schwarz product, by Cauchy–Schwarz applied to the two lists.

Two matrices pair as well as their singular values allow, and no better; and the best case is when the two matrices stretch the same directions by the same ranking.

The proof takes the two singular value decompositions apart and finds, sitting between them, a square array of non-negative weights whose rows and columns each add up to at most 1. Everything then reduces to a fact about such arrays, which is worth isolating first.

20.5.2 Weights that do not add up to more than one

Definition 20.5.1 — Doubly Substochastic Matrix

A matrix $\mathbf{D} = (d_{kl}) \in M_p(\mathbb{R})$ is **doubly substochastic** if

(S1) $d_{kl} \geq 0$ for all k, l;
(S2) $\sum_{l=1}^{p} d_{kl} \leq 1$ for **every** row index k; and
(S3) $\sum_{k=1}^{p} d_{kl} \leq 1$ for **every** column index l.

In words: the entries are non-negative, and no row and no column adds up to more than one. Replacing both "≤ 1" by "$= 1$" gives the doubly stochastic matrices of Definition 17.8.4, so every doubly stochastic matrix is doubly substochastic, and in particular so is every permutation matrix. The zero matrix is doubly substochastic, which the stochastic condition excludes; that degenerate case matters, because it is what lets a substochastic matrix throw weight away instead of merely moving it. A non-example by minimal change: $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ satisfies (S1) and (S3) but its first row adds to 2, so (S2) fails.

The lemma we need says that such an array of weights cannot help two decreasing non-negative lists pair better than they do term by term.

Lemma 20.5.1 — Substochastic Pairing

Let $x_1 \geq \cdots \geq x_p \geq 0$ and $y_1 \geq \cdots \geq y_p \geq 0$ be real numbers, and let $\mathbf{D} \in M_p(\mathbb{R})$ be doubly substochastic. Then

$$\sum_{k=1}^{p}\sum_{l=1}^{p} d_{kl}\, x_k y_l \;\leq\; \sum_{k=1}^{p} x_k y_k.$$

Idea. Decreasing non-negative lists are non-negative combinations of the "staircase" lists $(1,\dots,1,0,\dots,0)$: write $x_k = \sum_{i\geq k}(x_i - x_{i+1})$. Summation by parts in both variables at once turns each side into a non-negative combination of the same coefficients, and all that is left to compare is what multiplies them: on the left a partial sum of $\mathbf{D}$ over a top-left rectangle, on the right the number $\min(i,j)$. The two substochastic conditions

say exactly that an $i \times j$ rectangle of $\mathbf{D}$ holds at most $\min(i, j)$.

Proof. Put $x_{p+1} = y_{p+1} = 0$ and, for $1 \le i \le p$, write $\Delta x_i = x_i - x_{i+1}$ and $\Delta y_i = y_i - y_{i+1}$. These are ≥ 0, since the lists are decreasing and $x_p, y_p \ge 0$, and telescoping gives

$$x_k = \sum_{i=k}^{p} \Delta x_i, \qquad y_l = \sum_{j=l}^{p} \Delta y_j \qquad (1 \le k, l \le p).$$

Substituting both and exchanging the order of the four finite sums,

$$\sum_{k,l} d_{kl} x_k y_l = \sum_{i=1}^{p} \sum_{j=1}^{p} \Delta x_i \, \Delta y_j \, S_{ij}, \qquad S_{ij} \coloneqq \sum_{k \le i} \sum_{l \le j} d_{kl},$$

because the pair (k, l) contributes to (i, j) exactly when $k \le i$ and $l \le j$. The same substitution with $\mathbf{D}$ replaced by the identity matrix gives

$$\sum_{k=1}^{p} x_k y_k = \sum_{i=1}^{p} \sum_{j=1}^{p} \Delta x_i \, \Delta y_j \, \min(i, j),$$

since the number of $k \le \min(i, j)$ is $\min(i, j)$.

It remains to compare S_{ij} with $\min(i, j)$. Summing (S2) over the i rows $k \le i$ and discarding the non-negative entries with $l > j$ gives $S_{ij} \le i$; summing (S3) over the j columns $l \le j$ gives $S_{ij} \le j$. Hence $S_{ij} \le \min(i, j)$ for all i, j. Since every Δx_i and every Δy_j is ≥ 0, replacing S_{ij} by $\min(i, j)$ can only increase the double sum. This proves the lemma.

■

Taking $\mathbf{D}$ to be the permutation matrix of $\pi \in S_p$ gives $\sum_k x_k y_{\pi(k)} \le \sum_k x_k y_k$: two decreasing lists pair best when they are paired in order. That is the **rearrangement inequality**, and it is the special case that carries the meaning of the lemma. The general case allows the weights to be spread out and partly thrown away, and says that neither helps.

Quick check. Where does the proof use $x_p \ge 0$ and $y_p \ge 0$, rather than just the decrease? Find a doubly substochastic $\mathbf{D}$ and a decreasing pair with a negative entry for which the conclusion fails.

Solution. It is used to make $\Delta x_p = x_p$ and $\Delta y_p = y_p$ non-negative, which is what allows S_{ij} to be replaced by the larger $\min(i, j)$ in the last step. Without it the conclusion fails: take $p = 2$, $\mathbf{x} = (1, -1)$, $\mathbf{y} = (1, 1)$ and $\mathbf{D} = \operatorname{diag}(1, 0)$, which is doubly substochastic. The left side is 1 and the right side is $1 - 1 = 0$, so the asserted inequality $1 \le 0$ is false. The proof breaks at the step named: here $\Delta x_2 = x_2 = -1 < 0$ and $\Delta y_2 = 1$, so replacing $S_{22} = 1$ by $\min(2, 2) = 2$ lowers the double sum instead of raising it. Throwing weight away helps when a pairing is negative, and that is exactly what non-negativity rules out.

20.5.3 The trace inequality

Theorem 20.5.2 — Von Neumann's Trace Inequality

Let $\mathbf{A}, \mathbf{B} \in M_{m\times n}(F)$ with $F = \mathbb{R}$ or $\mathbb{C}$, and let $p = \min(m, n)$. Then

$$\left|\operatorname{tr}(\mathbf{A}^*\mathbf{B})\right| \;\le\; \sum_{i=1}^{p} \sigma_i(\mathbf{A})\,\sigma_i(\mathbf{B}).$$

The bound is attained whenever $\mathbf{A}$ and $\mathbf{B}$ have **aligned** singular value decompositions, that is, whenever there are unitary $\mathbf{U} \in M_m(F)$ and $\mathbf{V} \in M_n(F)$ with $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}_\mathbf{A}\mathbf{V}^*$ and $\mathbf{B} = \mathbf{U}\mathbf{\Sigma}_\mathbf{B}\mathbf{V}^*$, where $\mathbf{\Sigma}_\mathbf{A}, \mathbf{\Sigma}_\mathbf{B} \in M_{m\times n}(F)$ carry $\sigma_i(\mathbf{A})$ and $\sigma_i(\mathbf{B})$ on the main diagonal and zeros elsewhere.

Idea. Write both singular value decompositions and push the four unitary factors into two: one, $\mathbf{M}$, sits between the two diagonal matrices, the other, $\mathbf{N}$, closes the trace up. Multiplying out, the trace becomes $\sum_{k,l} \sigma_k(\mathbf{A})\sigma_l(\mathbf{B})m_{kl}n_{lk}$: every pairing of a singular value of $\mathbf{A}$ with one of $\mathbf{B}$ occurs, weighted by one entry of each unitary. The weights $|m_{kl}n_{lk}|$ are exactly where unitarity is spent — each row of $\mathbf{M}$ and each column of $\mathbf{N}$ is a unit vector, so Cauchy–Schwarz makes the weight array doubly substochastic — and Lemma 20.5.1 finishes.

Proof. Fix singular value decompositions $\mathbf{A} = \mathbf{U}_1\mathbf{\Sigma}_\mathbf{A}\mathbf{V}_1^*$ and $\mathbf{B} = \mathbf{U}_2\mathbf{\Sigma}_\mathbf{B}\mathbf{V}_2^*$ (Theorem 12.8.1), with $\mathbf{U}_1, \mathbf{U}_2 \in M_m(F)$ and $\mathbf{V}_1, \mathbf{V}_2 \in M_n(F)$ unitary and $\mathbf{\Sigma}_\mathbf{A}, \mathbf{\Sigma}_\mathbf{B}$ as in the statement. Put

$$\mathbf{M} \coloneqq \mathbf{U}_1^*\mathbf{U}_2 \in M_m(F), \qquad \mathbf{N} \coloneqq \mathbf{V}_2^*\mathbf{V}_1 \in M_n(F),$$

both unitary, being products of unitary matrices. Then $\mathbf{A}^*\mathbf{B} = \mathbf{V}_1\mathbf{\Sigma}_\mathbf{A}^*\mathbf{M}\mathbf{\Sigma}_\mathbf{B}\mathbf{V}_2^*$, so by Theorem 0.9.6 (3), moving the factor $\mathbf{V}_1$ to the back,

$$\operatorname{tr}(\mathbf{A}^*\mathbf{B}) = \operatorname{tr}\big(\mathbf{\Sigma}_\mathbf{A}^*\,\mathbf{M}\,\mathbf{\Sigma}_\mathbf{B}\,\mathbf{N}\big).$$

Now compute that trace entry by entry. The matrix $\mathbf{\Sigma}_\mathbf{A}^* \in M_{n\times m}(F)$ has (k, a) entry $\sigma_k(\mathbf{A})\delta_{ka}$, which vanishes unless $k = a \le p$, and $\mathbf{\Sigma}_\mathbf{B}$ has (b, l) entry $\sigma_b(\mathbf{B})\delta_{bl}$, which vanishes unless $b = l \le p$. Hence

$$\operatorname{tr}(\mathbf{A}^*\mathbf{B}) = \sum_{k=1}^{p}\sum_{l=1}^{p} \sigma_k(\mathbf{A})\,\sigma_l(\mathbf{B})\,m_{kl}\,n_{lk}, \tag{20.5.1}$$

all indices being in range because $p \le m$ and $p \le n$. By the triangle inequality (Theorem 0.6.4),

$$\left|\operatorname{tr}(\mathbf{A}^*\mathbf{B})\right| \;\le\; \sum_{k=1}^{p}\sum_{l=1}^{p} \sigma_k(\mathbf{A})\,\sigma_l(\mathbf{B})\,d_{kl}, \qquad d_{kl} \coloneqq |m_{kl}|\,|n_{lk}|.$$

Claim. $\mathbf{D} = (d_{kl})_{k,l\le p}$ is doubly substochastic.

Proof. Each $d_{kl} \ge 0$, which is (S1). Fix $k \le p$. By Cauchy–Schwarz (Theorem 10.1.5) in $\mathbb{R}^p$, and then by extending both sums to their full ranges $l \le m$ and $l \le n$, which only adds non-negative terms,

$$\sum_{l=1}^{p} |m_{kl}||n_{lk}| \le \Big(\sum_{l=1}^{m} |m_{kl}|^2\Big)^{1/2} \Big(\sum_{l=1}^{n} |n_{lk}|^2\Big)^{1/2} = 1,$$

because row k of the unitary $\mathbf{M}$ and column k of the unitary $\mathbf{N}$ are unit vectors. This is (S2), and (S3) is the same computation with the roles of the two indices exchanged: column l of $\mathbf{M}$ and row l of $\mathbf{N}$ are unit vectors as well.

■

The lists $\sigma_1(\mathbf{A}) \ge \cdots \ge \sigma_p(\mathbf{A}) \ge 0$ and $\sigma_1(\mathbf{B}) \ge \cdots \ge \sigma_p(\mathbf{B}) \ge 0$ are decreasing and non-negative (Definition 12.8.1), so Lemma 20.5.1 applies and gives

$$\sum_{k,l} \sigma_k(\mathbf{A})\sigma_l(\mathbf{B}) d_{kl} \;\le\; \sum_{k=1}^{p} \sigma_k(\mathbf{A})\sigma_k(\mathbf{B}),$$

which is the stated bound.

For the last sentence, suppose $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}_{\mathbf{A}}\mathbf{V}^*$ and $\mathbf{B} = \mathbf{U}\mathbf{\Sigma}_{\mathbf{B}}\mathbf{V}^*$ with the same $\mathbf{U}$ and $\mathbf{V}$. Then $\mathbf{A}^*\mathbf{B} = \mathbf{V}\mathbf{\Sigma}_{\mathbf{A}}^*\mathbf{U}^*\mathbf{U}\mathbf{\Sigma}_{\mathbf{B}}\mathbf{V}^* = \mathbf{V}\mathbf{\Sigma}_{\mathbf{A}}^*\mathbf{\Sigma}_{\mathbf{B}}\mathbf{V}^*$, and $\mathbf{\Sigma}_{\mathbf{A}}^*\mathbf{\Sigma}_{\mathbf{B}}$ is the $n \times n$ diagonal matrix with entries $\sigma_i(\mathbf{A})\sigma_i(\mathbf{B})$ for $i \le p$ and zeros after. Taking traces and using Theorem 0.9.6 (3) again, $\operatorname{tr}(\mathbf{A}^*\mathbf{B}) = \sum_{i\le p} \sigma_i(\mathbf{A})\sigma_i(\mathbf{B})$. This proves the theorem.

■

Three things about the proof are worth keeping. The weight matrix $\mathbf{D}$ is where all the information about the two sets of singular directions has gone; the only thing about it that survives is a pair of inequalities. Unitarity is spent exactly once, on the unit rows and columns inside the claim, and nothing else about $\mathbf{M}$ and $\mathbf{N}$ is used. And the equality case shows the bound is not merely an upper bound to be improved later: it is attained for every prescribed pair of singular value lists.

Warning. The singular values are paired **in matching order**, and no other pairing gives an upper bound. For $\mathbf{A} = \operatorname{diag}(2, 1)$ and $\mathbf{B} = \operatorname{diag}(20, 15)$ the reversed pairing is $2 \cdot 15 + 1 \cdot 20 = 50$, while $\operatorname{tr}(\mathbf{A}^*\mathbf{B}) = 40 + 15 = 55$. What is true for every permutation π is the **lower** bound $\sum_i \sigma_i(\mathbf{A})\sigma_{\pi(i)}(\mathbf{B}) \le \sum_i \sigma_i(\mathbf{A})\sigma_i(\mathbf{B})$, which is the rearrangement inequality above.

Example. (A strict case and an equality case)

Let

$$\mathbf{A} = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 12 & -12 \\ 16 & 9 \end{pmatrix}, \qquad \mathbf{B}' = \begin{pmatrix} 20 & 0 \\ 0 & 15 \end{pmatrix}.$$

Check that $\mathbf{B}$ and $\mathbf{B}'$ have the same singular values, and compare the two sides of

Theorem 20.5.2 for the pairs $(\mathbf{A}, \mathbf{B})$ and $(\mathbf{A}, \mathbf{B}')$.

Solution. For $\mathbf{B}$,

$$\mathbf{B}^\top \mathbf{B} = \begin{pmatrix} 144+256 & -144+144 \\ -144+144 & 144+81 \end{pmatrix} = \begin{pmatrix} 400 & 0 \\ 0 & 225 \end{pmatrix},$$

so $\sigma(\mathbf{B}) = (20, 15)$ by Definition 12.8.1, and $\sigma(\mathbf{B}') = (20, 15)$ as well since $\mathbf{B}'$ is diagonal with positive decreasing entries. Also $\sigma(\mathbf{A}) = (2, 1)$. So both pairs have the same right-hand side,

$$\sigma_1(\mathbf{A})\sigma_1(\mathbf{B}) + \sigma_2(\mathbf{A})\sigma_2(\mathbf{B}) = 2 \cdot 20 + 1 \cdot 15 = 55.$$

On the left, $\operatorname{tr}(\mathbf{A}^\top \mathbf{B}') = 2{\cdot}20{+}1{\cdot}15 = 55$: equality. And $\operatorname{tr}(\mathbf{A}^\top \mathbf{B}) = 2{\cdot}12{+}1{\cdot}9 = 33 < 55$: strict.

The reason is visible in the decompositions. Both $\mathbf{A}$ and $\mathbf{B}'$ are diagonal with decreasing non-negative entries, so $\mathbf{A} = \mathbf{I}\mathbf{A}\mathbf{I}^*$ and $\mathbf{B}' = \mathbf{I}\mathbf{B}'\mathbf{I}^*$ are aligned. For $\mathbf{B}$, on the other hand, $\mathbf{B} = \mathbf{U}_2 \operatorname{diag}(20, 15)$ with

$$\mathbf{U}_2 = \tfrac{1}{5}\begin{pmatrix} 3 & -4 \\ 4 & 3 \end{pmatrix},$$

a rotation, so in the notation of the proof $\mathbf{M} = \mathbf{U}_1^* \mathbf{U}_2 = \mathbf{U}_2$ and $\mathbf{N} = \mathbf{I}$. The weight matrix is $\mathbf{D} = \operatorname{diag}(\tfrac{3}{5}, \tfrac{3}{5})$, doubly substochastic and far from a permutation, and Eq. 20.5.1 reads $2 \cdot 20 \cdot \tfrac{3}{5} + 1 \cdot 15 \cdot \tfrac{3}{5} = 24 + 9 = 33$. The rotation has thrown away two fifths of each weight, and that is exactly the loss.

20.5.4 The dual of a unitarily invariant norm

The trace inequality is a statement about a pairing, so it is really a statement about duality. Recall the dual norm of Definition 17.4.4: it measures a vector by the largest value of the pairing against vectors the given norm calls short. On matrices, the pairing to use is the Frobenius one, and the result is exactly as clean as one could hope: dualizing a unitarily invariant norm dualizes its symmetric gauge and nothing else.

Corollary 20.5.3 — Duality of Unitarily Invariant Norms

Let $\|\!|\cdot|\!\|$ be a unitarily invariant norm on $M_{m\times n}(F)$ (Definition 20.4.1) with symmetric gauge Φ on $\mathbb{R}^p$, $p = \min(m, n)$, so that $\|\!|\mathbf{A}|\!\| = \Phi(\sigma(\mathbf{A}))$ (Lemma 20.4.1). Define

$$\|\!|\mathbf{B}|\!\|^* := \max\bigl\{|\operatorname{tr}(\mathbf{B}^*\mathbf{A})| \;:\; \mathbf{A} \in M_{m\times n}(F),\ \|\!|\mathbf{A}|\!\| \le 1\bigr\}.$$

Then $\|\!|\mathbf{B}|\!\|^* = \Phi^*(\sigma(\mathbf{B}))$, where Φ^* is the dual gauge of Definition 20.3.3. In particular $\|\!|\cdot|\!\|^*$ is again a unitarily invariant norm, the trace norm $\|\cdot\|_{(p)}$ of Definition 20.4.2 and the spectral norm $\|\cdot\|_2$ are dual to each other, and the Frobenius norm is self-dual.

Idea. Both inequalities are one line each once the trace inequality is available. For $\le$, bound the pairing by $\sum_i \sigma_i(\mathbf{A})\sigma_i(\mathbf{B})$ and then by $\Phi(\sigma(\mathbf{A}))\Phi^*(\sigma(\mathbf{B}))$, which is what a dual norm is for. For $\ge$, build the competitor $\mathbf{A}$ out of $\mathbf{B}$: take the vector where

$\Phi^*(\sigma(\mathbf{B}))$ is attained and hang it on $\mathbf{B}$'s own singular vectors, which makes the pair aligned and turns the trace inequality into an equality.

Proof. Write $\sigma(\mathbf{B}) \in \mathbb{R}^p$ for the singular value list of $\mathbf{B}$, and fix a singular value decomposition $\mathbf{B} = \mathbf{U}\mathbf{\Sigma}_\mathbf{B}\mathbf{V}^*$ (Theorem 12.8.1).

($\leq$) Let $|||\mathbf{A}||| \leq 1$. By Theorem 20.5.2 and then by the defining property of a dual norm (Proposition 17.4.6 (b), applied to the norm Φ of Definition 20.3.3), which gives $\langle \mathbf{x}, \mathbf{y} \rangle \leq \Phi(\mathbf{x})\Phi^*(\mathbf{y})$ for all $\mathbf{x}, \mathbf{y}$,

$$\begin{aligned} |\mathrm{tr}(\mathbf{B}^*\mathbf{A})| &\leq \sum_{i=1}^{p} \sigma_i(\mathbf{A})\sigma_i(\mathbf{B}) \leq \Phi(\sigma(\mathbf{A}))\, \Phi^*(\sigma(\mathbf{B})) \\ &= |||\mathbf{A}|||\ \Phi^*(\sigma(\mathbf{B})) \leq \Phi^*(\sigma(\mathbf{B})). \end{aligned}$$

($\geq$) By Definition 20.3.3 there is $\mathbf{x} \in \mathbb{R}^p$ with $\Phi(\mathbf{x}) \leq 1$ and $\langle \mathbf{x}, \sigma(\mathbf{B}) \rangle = \Phi^*(\sigma(\mathbf{B}))$. We may assume $x_1 \geq \cdots \geq x_p \geq 0$. Indeed, replacing each x_i by $|x_i|$ leaves $\Phi(\mathbf{x})$ unchanged, by the sign invariance in Definition 20.3.1, and does not decrease $\langle \mathbf{x}, \sigma(\mathbf{B}) \rangle$ because every $\sigma_i(\mathbf{B}) \geq 0$; sorting the result decreasingly leaves Φ unchanged, by the permutation invariance in Definition 20.3.1, and does not decrease $\langle \mathbf{x}, \sigma(\mathbf{B}) \rangle$ by the rearrangement inequality (Lemma 20.5.1 with a permutation matrix). Since $\Phi^*(\sigma(\mathbf{B}))$ is by definition the largest value of $\langle \cdot, \sigma(\mathbf{B}) \rangle$ on $\{\Phi \leq 1\}$, the value is still exactly $\Phi^*(\sigma(\mathbf{B}))$. Now put

$$\mathbf{A} \coloneqq \mathbf{U}\,\mathbf{X}\,\mathbf{V}^*, \qquad \mathbf{X} \in M_{m\times n}(F) \text{ with } (\mathbf{X})_{ii} = x_i \ (i \leq p)$$

and all other entries 0. Since $x_1 \geq \cdots \geq x_p \geq 0$, this is a singular value decomposition of $\mathbf{A}$, so $\sigma(\mathbf{A}) = \mathbf{x}$ and $|||\mathbf{A}||| = \Phi(\mathbf{x}) \leq 1$. It is aligned with the chosen decomposition of $\mathbf{B}$, so the equality case of Theorem 20.5.2 gives

$$|\mathrm{tr}(\mathbf{B}^*\mathbf{A})| = \sum_{i=1}^{p} x_i \sigma_i(\mathbf{B}) = \Phi^*(\sigma(\mathbf{B})).$$

Hence the maximum is at least $\Phi^*(\sigma(\mathbf{B}))$, and the two bounds together prove the formula. (The maximum is attained, by the competitor just built.)

The remaining claims follow. By Theorem 20.3.5, Φ^* is a symmetric gauge, so $|||\cdot|||^*$ is the unitarily invariant norm it corresponds to under Theorem 20.4.3. The trace norm is the one with $\Phi = \|\cdot\|_1$ and the spectral norm the one with $\Phi = \|\cdot\|_\infty$, by Lemma 20.4.1 and Theorem 15.3.3 (c); these gauges are dual to each other by Proposition 17.4.7 (a), (b). The Frobenius norm has $\Phi = \|\cdot\|_2$, which is self-dual by Proposition 17.4.7 (c). This proves the corollary.

■

So the two extreme **normalized** unitarily invariant norms of Section 4 — the smallest, $\|\cdot\|_2$, and the largest, the trace norm, extreme among the normalized ones by Proposition 20.4.4 (c) — are exchanged by duality, and the Frobenius norm sits at the fixed point in the middle. Since $\Phi^{**} = \Phi$ (Theorem 20.3.5), dualizing twice returns the original norm.

Quick check. What does Corollary 20.5.3 say for $\mathbf{B} = \mathbf{e}_1\mathbf{e}_1^*$, a single matrix unit, and $|||\cdot|||$ the spectral norm?

Solution. Here $\sigma(\mathbf{B}) = (1, 0, \dots, 0)$, and the gauge of the spectral norm is $\|\cdot\|_\infty$, whose dual is $\|\cdot\|_1$. So $\|\mathbf{B}\|^* = \|(1, 0, \dots, 0)\|_1 = 1$: the largest value of $|\mathrm{tr}(\mathbf{B}^*\mathbf{A})| = |a_{11}|$ over matrices with $\|\mathbf{A}\|_2 \le 1$ is 1, attained at $\mathbf{A} = \mathbf{e}_1\mathbf{e}_1^*$. An entry of a matrix never exceeds its spectral norm, and for a matrix unit that is sharp.

20.5.5 Exercises

20.5.5.1 A. Check your understanding

Exercise A1.

(a) Define a doubly substochastic matrix, and say which doubly substochastic matrices are doubly stochastic.

(b) State Theorem 20.5.2, with its hypotheses, and say what "aligned" means.

(c) Determine whether the following is true for all $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$, and justify your answer: $|\mathrm{tr}(\mathbf{AB})| \le \sum_i \sigma_i(\mathbf{A})\sigma_i(\mathbf{B})$.

(d) Where in the proof of Theorem 20.5.2 is the unitarity of $\mathbf{M}$ and $\mathbf{N}$ used, and what exactly is deduced from it?

(e) Determine whether the following is true, and justify your answer: if $\mathrm{tr}(\mathbf{A}^*\mathbf{B}) = \sum_i \sigma_i(\mathbf{A})\sigma_i(\mathbf{B})$ then $\mathbf{A} = \mathbf{B}$.

Solution.

(a) A square real matrix with non-negative entries whose every row sum and every column sum is at most 1 (Definition 20.5.1). It is doubly stochastic exactly when all those sums equal 1.

(b) For $\mathbf{A}, \mathbf{B} \in M_{m\times n}(F)$ and $p = \min(m, n)$, $|\mathrm{tr}(\mathbf{A}^*\mathbf{B})| \le \sum_{i\le p} \sigma_i(\mathbf{A})\sigma_i(\mathbf{B})$. The pair is aligned when there are unitary $\mathbf{U}, \mathbf{V}$ with $\mathbf{A} = \mathbf{U}\mathbf{\Sigma_A}\mathbf{V}^*$ and $\mathbf{B} = \mathbf{U}\mathbf{\Sigma_B}\mathbf{V}^*$, the **same** $\mathbf{U}$ and $\mathbf{V}$ for both; then equality holds.

(c) True. Apply Theorem 20.5.2 to the pair $\mathbf{A}^*$ and $\mathbf{B}$, using $\mathrm{tr}(\mathbf{AB}) = \mathrm{tr}((\mathbf{A}^*)^*\mathbf{B})$ and $\sigma(\mathbf{A}^*) = \sigma(\mathbf{A})$, which is Proposition 20.4.4 (a).

(d) Only in the claim, and only to say that each row of $\mathbf{M}$ and each column of $\mathbf{N}$ is a unit vector. Cauchy–Schwarz then makes the weight array doubly substochastic. Nothing else about $\mathbf{M}$ and $\mathbf{N}$ is used.

(e) False. Take $\mathbf{A} = \mathbf{I}_2$ and $\mathbf{B} = 2\mathbf{I}_2$: both sides are 4, and $\mathbf{A} \ne \mathbf{B}$. The theorem says that alignment forces equality, and $\mathbf{A}$ and $\mathbf{B}$ are aligned, with $\mathbf{U} = \mathbf{V} = \mathbf{I}$; it says nothing that would force the two matrices to be equal.

20.5.5.2 B. Practice

Exercise B1: Both sides of the inequality.

Let

$$\mathbf{A} = \begin{pmatrix} 3 & 0 \\ 0 & 1 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 0 & 4 \\ 2 & 0 \end{pmatrix}.$$

Compute $\mathrm{tr}(\mathbf{A}^\top\mathbf{B})$, the singular values of both matrices, and both sides of Theo-

rem 20.5.2. Then find a matrix $\mathbf{B}''$ with the same singular values as $\mathbf{B}$ for which equality holds.

Solution. $\mathbf{A}^\top\mathbf{B} = \left(\begin{smallmatrix} 0 & 12 \\ 2 & 0 \end{smallmatrix}\right)$, so $\operatorname{tr}(\mathbf{A}^\top\mathbf{B}) = 0$. Since $\mathbf{A}$ is diagonal with positive decreasing entries, $\sigma(\mathbf{A}) = (3, 1)$. For $\mathbf{B}$, $\mathbf{B}^\top\mathbf{B} = \operatorname{diag}(4, 16)$, so $\sigma(\mathbf{B}) = (4, 2)$. The right-hand side is $3 \cdot 4 + 1 \cdot 2 = 14$, and $0 \leq 14$ with a lot to spare: $\mathbf{B}$ sends the direction $\mathbf{A}$ stretches most to the one it stretches least.

For equality, align: take $\mathbf{B}'' = \operatorname{diag}(4, 2)$. Then $\operatorname{tr}(\mathbf{A}^\top\mathbf{B}'') = 12 + 2 = 14$, and $\sigma(\mathbf{B}'') = (4, 2)$.

Exercise B2: The trace against the trace norm.

Let $\mathbf{A} \in M_n(\mathbb{C})$.

(a) Prove that $|\operatorname{tr}\mathbf{A}| \leq \sum_{i=1}^{n} \sigma_i(\mathbf{A})$.

(b) Determine all $\mathbf{A}$ for which equality holds with $\mathbf{A}$ positive semidefinite.

Solution.

(a) Apply Theorem 20.5.2 with the pair $\mathbf{I}_n$ and $\mathbf{A}$, in that order: $\operatorname{tr}(\mathbf{I}^*\mathbf{A}) = \operatorname{tr}\mathbf{A}$, and $\sigma_i(\mathbf{I}) = 1$ for every i, so $|\operatorname{tr}\mathbf{A}| \leq \sum_i 1 \cdot \sigma_i(\mathbf{A})$.

(b) For $\mathbf{A} \succeq 0$ the eigenvalues are non-negative (Theorem 12.1.4) and, by the spectral theorem, $\mathbf{A} = \mathbf{U}\operatorname{diag}(\lambda_1, \ldots, \lambda_n)\mathbf{U}^*$ with $\lambda_i \geq 0$ decreasing; this is a singular value decomposition, so $\sigma_i(\mathbf{A}) = \lambda_i(\mathbf{A})$. Hence $\operatorname{tr}\mathbf{A} = \sum_i \lambda_i = \sum_i \sigma_i(\mathbf{A})$ by Corollary 11.1.4: equality holds for **every** positive semidefinite $\mathbf{A}$. (Consistently with the theorem, $\mathbf{I}$ and such an $\mathbf{A}$ are aligned, with $\mathbf{V} = \mathbf{U}$.)

Exercise B3: A weight matrix.

Let $\mathbf{A} = \operatorname{diag}(5, 1)$ and let $\mathbf{B} = \mathbf{U}\operatorname{diag}(2, 1)\mathbf{U}^*$ with $\mathbf{U} = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$. Write down the matrices $\mathbf{M}$ and $\mathbf{N}$ of the proof of Theorem 20.5.2 for this pair, the weight matrix $\mathbf{D}$, and verify Eq. 20.5.1 and the inequality numerically.

Solution. Take $\mathbf{U}_1 = \mathbf{V}_1 = \mathbf{I}$ for $\mathbf{A}$, and $\mathbf{U}_2 = \mathbf{U}$, $\mathbf{V}_2 = \mathbf{U}$ for $\mathbf{B}$ (the decomposition given is a singular value decomposition, since $\operatorname{diag}(2, 1)$ is diagonal with positive decreasing entries). Then $\mathbf{M} = \mathbf{U}_1^*\mathbf{U}_2 = \mathbf{U}$ and $\mathbf{N} = \mathbf{V}_2^*\mathbf{V}_1 = \mathbf{U}^*$, so

$$m_{kl}n_{lk} = u_{kl}\,\overline{u_{kl}} = |u_{kl}|^2 = \tfrac{1}{2}$$

for all k, l, and $\mathbf{D} = \frac{1}{2}\left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$, which is doubly stochastic, hence doubly substochastic. Now Eq. 20.5.1 gives

$$\operatorname{tr}(\mathbf{A}^*\mathbf{B}) = \tfrac{1}{2}(5 \cdot 2 + 5 \cdot 1 + 1 \cdot 2 + 1 \cdot 1) = \tfrac{18}{2} = 9,$$

which checks against $\mathbf{B} = \frac{1}{2}\left(\begin{smallmatrix} 3 & 1 \\ 1 & 3 \end{smallmatrix}\right)$ and $\operatorname{tr}(\mathbf{AB}) = \frac{1}{2}(5 \cdot 3 + 1 \cdot 3) = 9$. The bound is $5 \cdot 2 + 1 \cdot 1 = 11$, and $9 \leq 11$.

20.5.5.3 C. Going deeper

Exercise C1: The triangle inequality for the trace norm.

Write $|||\mathbf{A}|||_{(p)} = \sum_i \sigma_i(\mathbf{A})$ for the trace norm of Definition 20.4.2, $\mathbf{A} \in M_{m\times n}(\mathbb{C})$.

(a) Prove that $|||\mathbf{A}|||_{(p)} = \max\{|\mathrm{tr}(\mathbf{A}^*\mathbf{Q})| : \mathbf{Q} \in M_{m\times n}(\mathbb{C}),\ \|\mathbf{Q}\|_2 \le 1\}$.

(b) Hence deduce that $|||\cdot|||_{(p)}$ satisfies the triangle inequality, without using Lemma 20.4.2.

Hint: for (a), Corollary 20.5.3 with the spectral norm, read the other way round.

Solution.

(a) The spectral norm is a unitarily invariant norm, and its gauge is $\Phi = \|\cdot\|_\infty$ (Lemma 20.4.1, Theorem 15.3.3 (c)). By Corollary 20.5.3 applied to that norm, the maximum in the statement equals $\Phi^*(\sigma(\mathbf{A})) = \|\sigma(\mathbf{A})\|_1 = \sum_i \sigma_i(\mathbf{A})$, using Proposition 17.4.7 (b).

(b) Conjugate transposition is additive, so $\mathrm{tr}((\mathbf{A}+\mathbf{B})^*\mathbf{Q}) = \mathrm{tr}(\mathbf{A}^*\mathbf{Q}) + \mathrm{tr}(\mathbf{B}^*\mathbf{Q})$ for every $\mathbf{Q}$. Given $\mathbf{A}, \mathbf{B}$, choose by (a) a $\mathbf{Q}$ with $\|\mathbf{Q}\|_2 \le 1$ attaining the maximum for $\mathbf{A}+\mathbf{B}$; then, by the triangle inequality for the modulus (Theorem 0.6.4) and (a) again,

$$|||\mathbf{A}+\mathbf{B}|||_{(p)} = |\mathrm{tr}((\mathbf{A}+\mathbf{B})^*\mathbf{Q})| \le |\mathrm{tr}(\mathbf{A}^*\mathbf{Q})| + |\mathrm{tr}(\mathbf{B}^*\mathbf{Q})| \le |||\mathbf{A}|||_{(p)} + |||\mathbf{B}|||_{(p)}\,.$$

No step used Lemma 20.4.2: the route ran through the trace inequality and duality alone.

Exercise C2: The nearest unitary, again.

Let $\mathbf{A} \in M_n(\mathbb{C})$ with polar decomposition $\mathbf{A} = \mathbf{W}|\mathbf{A}|$ (Theorem 12.9.1).

(a) Prove that $\max\{\mathrm{Re}\,\mathrm{tr}(\mathbf{Q}^*\mathbf{A}) : \mathbf{Q} \in M_n(\mathbb{C}) \text{ unitary}\} = \sum_i \sigma_i(\mathbf{A})$, attained at $\mathbf{Q} = \mathbf{W}$.

(b) Deduce Corollary 12.9.2, that $\mathbf{W}$ minimizes $\|\mathbf{A}-\mathbf{Q}\|_F$ over unitary $\mathbf{Q}$.

Solution.

(a) For unitary $\mathbf{Q}$, $\sigma_i(\mathbf{Q}) = 1$ for every i, so Theorem 20.5.2 gives $\mathrm{Re}\,\mathrm{tr}(\mathbf{Q}^*\mathbf{A}) \le |\mathrm{tr}(\mathbf{Q}^*\mathbf{A})| \le \sum_i \sigma_i(\mathbf{A})$. For attainment, fix a singular value decomposition $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$ and recall from the proof of Theorem 12.9.1 that $\mathbf{W} = \mathbf{U}\mathbf{V}^*$. Then $\mathbf{W}^*\mathbf{A} = \mathbf{V}\mathbf{U}^*\mathbf{U}\mathbf{\Sigma}\mathbf{V}^* = \mathbf{V}\mathbf{\Sigma}\mathbf{V}^*$, whose trace is $\mathrm{tr}\,\mathbf{\Sigma} = \sum_i \sigma_i(\mathbf{A})$ by Theorem 0.9.6 (3); it is real.

(b) For unitary $\mathbf{Q}$, expanding in the Frobenius inner product,

$$\|\mathbf{A}-\mathbf{Q}\|_F^2 = \|\mathbf{A}\|_F^2 + n - 2\,\mathrm{Re}\,\mathrm{tr}(\mathbf{Q}^*\mathbf{A}),$$

since $\|\mathbf{Q}\|_F^2 = \mathrm{tr}(\mathbf{Q}^*\mathbf{Q}) = n$. Only the last term depends on $\mathbf{Q}$, and it enters with a minus sign, so minimizing the left side is maximizing $\mathrm{Re}\,\mathrm{tr}(\mathbf{Q}^*\mathbf{A})$. By (a) the maximum is attained at $\mathbf{Q} = \mathbf{W}$, which is Corollary 12.9.2.

20.6 Ky Fan Dominance

Three earlier chapters have deferred the same kind of statement to this one: that a matrix is closest to another in **every** unitarily invariant norm at once. Such a statement looks like infinitely many theorems, one for each norm. This section shows that it is one theorem about singular values, and that it can be tested on a short finite list of norms. Then it collects the debts.

20.6.1 One weak majorization, every norm

Section 3 proved that a symmetric gauge respects weak majorization, and Section 4 matched the gauges with the unitarily invariant norms. Put together, they say that a weak majorization of singular values forces an inequality of norms. What is new here is the **converse**: nothing else forces it, and the Ky Fan k-norms already see everything.

To compare two matrices in every unitarily invariant norm, compare the running totals of their singular values.

Theorem 20.6.1 — Ky Fan Dominance Theorem

Let $\mathbf{A}, \mathbf{B} \in M_{m\times n}(F)$ with $F = \mathbb{R}$ or $\mathbb{C}$, and let $p = \min(m, n)$. The following are equivalent.

(a) $\sigma(\mathbf{A}) \prec_w \sigma(\mathbf{B})$, that is, $\sum_{i\le k} \sigma_i(\mathbf{A}) \le \sum_{i\le k} \sigma_i(\mathbf{B})$ for every $k = 1, \dots, p$.
(b) $|||\mathbf{A}||| \le |||\mathbf{B}|||$ for **every** unitarily invariant norm $|||\cdot|||$ on $M_{m\times n}(F)$.

Idea.

(a) $\Rightarrow$ (b) is the dictionary of Sections 3 and 4 read in one direction: a unitarily invariant norm is a symmetric gauge evaluated at the singular values, and a symmetric gauge is monotone under weak majorization of non-negative vectors. For (b) $\Rightarrow$ (a) we need, for each k, a unitarily invariant norm that computes the k-th running total. The Ky Fan k-norm is exactly that, so the p inequalities in (a) are p of the infinitely many inequalities in (b).

Proof.

(a) $\Rightarrow$ (b). Let $|||\cdot|||$ be a unitarily invariant norm and let Φ be its symmetric gauge, so that $|||\mathbf{M}||| = \Phi(\sigma(\mathbf{M}))$ for every $\mathbf{M}$ (Theorem 20.4.3). The vectors $\sigma(\mathbf{A})$ and $\sigma(\mathbf{B})$ have non-negative entries (Definition 12.8.1), so Theorem 20.3.4 (b) applies to the hypothesis $\sigma(\mathbf{A}) \prec_w \sigma(\mathbf{B})$ and gives $\Phi(\sigma(\mathbf{A})) \le \Phi(\sigma(\mathbf{B}))$, which is $|||\mathbf{A}||| \le |||\mathbf{B}|||$.

(b) $\Rightarrow$ (a). Fix $k \in \{1, \dots, p\}$. Section 3's k-th Ky Fan gauge $\Phi_k(\mathbf{x}) = \sum_{i\le k} |x|_i^{\downarrow}$ (Definition 20.3.2) is a symmetric gauge function, so by Theorem 20.4.3

$$|||\mathbf{M}|||_{(k)} \coloneqq \Phi_k(\sigma(\mathbf{M})) = \sum_{i=1}^{k} \sigma_i(\mathbf{M})$$

is a unitarily invariant norm on $M_{m\times n}(F)$ — the Ky Fan k-norm of Defini-

tion 20.4.2 — the second equality holding because $\sigma(\mathbf{M})$ is already non-negative and decreasing, so that its k largest absolute values are its first k entries. Applying (b) to this one norm gives

$$\sum_{i=1}^{k} \sigma_i(\mathbf{A}) \;\le\; \sum_{i=1}^{k} \sigma_i(\mathbf{B}).$$

As k was arbitrary and both lists are decreasing, this is (a), by Definition 16.8.1. This proves the theorem.

■

The theorem is a translation device, and it will be used in one direction almost every time: to prove an inequality for every unitarily invariant norm, produce the weak majorization. Note also what it says about testing: the condition "for every unitarily invariant norm" is equivalent to "for the p Ky Fan norms", so a statement quantified over an infinite family of norms is decided by finitely many numbers.

Warning. One norm is never enough. For $\mathbf{A} = \operatorname{diag}(1,1)$ and $\mathbf{B} = \operatorname{diag}(1,0)$ the spectral norms agree, $\|\mathbf{A}\|_2 = \|\mathbf{B}\|_2 = 1$, yet $\sigma(\mathbf{A}) = (1,1)$ is not weakly majorized by $\sigma(\mathbf{B}) = (1,0)$, and indeed the trace norms are 2 and 1. Dominance needs **all** the running totals, and it compares matrices of the **same size**, since otherwise the two sides are norms on different spaces.

Quick check. Let $\mathbf{A}, \mathbf{B} \in M_{m\times n}(F)$ satisfy $\sigma_i(\mathbf{A}) \le \sigma_i(\mathbf{B})$ for every i. Does $|||\mathbf{A}||| \le |||\mathbf{B}|||$ hold for every unitarily invariant norm?

Solution. Yes. Entrywise domination of two decreasing non-negative lists gives $\sum_{i\le k} \sigma_i(\mathbf{A}) \le \sum_{i\le k} \sigma_i(\mathbf{B})$ for every k, which is $\sigma(\mathbf{A}) \prec_w \sigma(\mathbf{B})$; now apply Theorem 20.6.1. The converse fails: $\sigma(\mathbf{A}) = (1,1)$ and $\sigma(\mathbf{B}) = (2,0)$ satisfy $\sigma(\mathbf{A}) \prec_w \sigma(\mathbf{B})$ with $\sigma_2(\mathbf{A}) > \sigma_2(\mathbf{B})$.

20.6.2 Low-rank approximation in every unitarily invariant norm

Chapter 12 §10 proved that the truncated singular value decomposition $\mathbf{A}_k$ is the best rank-k approximation in the Frobenius norm, and Chapter 16 §09 proved the same for the spectral norm. Both promised more. Chapter 12 §10 said that the two statements are "instances of one theorem: $\mathbf{A}_k$ is a best rank-k approximation in **every** unitarily invariant norm", and predicted the shape of the proof: "it needs inequalities between the singular values of $\mathbf{A}$ and of $\mathbf{A} - \mathbf{B}$, not a projection argument". Chapter 15 §08 recorded the same debt — "The version covering every unitarily invariant norm at once is Chapter 20's" — and Chapter 16 §09 said that the common minimizer "is optimal in every unitarily invariant norm at once, which is Chapter 20's theorem". Here it is, by the predicted route.

Corollary 20.6.2 — Eckart–Young Theorem in Every Unitarily Invariant Norm

Let $\mathbf{A} \in M_{m\times n}(F)$ with singular values $\sigma_1 \ge \cdots \ge \sigma_p$, $p = \min(m,n)$, let $0 \le k \le p$,

and let $\mathbf{A}_k$ be a truncation of Definition 12.10.1. Then for **every** $\mathbf{B} \in M_{m\times n}(F)$ with $\operatorname{rank}\mathbf{B} \le k$ and **every** unitarily invariant norm on $M_{m\times n}(F)$,

$$\|\mathbf{A}-\mathbf{A}_k\| \;\le\; \|\mathbf{A}-\mathbf{B}\|,$$

and the minimum value is $\|\mathbf{A}-\mathbf{A}_k\| = \Phi(\sigma_{k+1},\dots,\sigma_p,0,\dots,0)$, where Φ is the symmetric gauge of the norm.

Idea. The singular values of the error $\mathbf{A}-\mathbf{A}_k$ are the discarded $\sigma_{k+1},\dots,\sigma_p$, padded with zeros. For an arbitrary competitor $\mathbf{B}$ of rank at most k, Weyl's inequality for singular values, applied with the splitting $\mathbf{A} = (\mathbf{A}-\mathbf{B})+\mathbf{B}$, says that $\mathbf{B}$ can shift the singular value list of $\mathbf{A}$ by at most k places, because $\sigma_{k+1}(\mathbf{B}) = 0$. That is precisely $\sigma_i(\mathbf{A}-\mathbf{B}) \ge \sigma_{k+i}(\mathbf{A})$: the truncation wins index by index, which is more than dominance needs.

Proof. **The error of the truncation.** Fix the singular value decomposition $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$ (Theorem 12.8.1) used to form $\mathbf{A}_k = \sum_{i\le k}\sigma_i\mathbf{u}_i\mathbf{v}_i^*$ (Definition 12.10.1). Then

$$\mathbf{A}-\mathbf{A}_k = \sum_{i>k}\sigma_i\mathbf{u}_i\mathbf{v}_i^* = \mathbf{U}\mathbf{\Sigma}^{(k)}\mathbf{V}^*,$$

where $\mathbf{\Sigma}^{(k)}$ is $\mathbf{\Sigma}$ with its first k diagonal entries replaced by 0. Since $\mathbf{U}$ and $\mathbf{V}$ are unitary, $(\mathbf{A}-\mathbf{A}_k)^*(\mathbf{A}-\mathbf{A}_k) = \mathbf{V}(\mathbf{\Sigma}^{(k)})^*\mathbf{\Sigma}^{(k)}\mathbf{V}^*$ has eigenvalues $\sigma_{k+1}^2,\dots,\sigma_p^2$ together with zeros, so by Definition 12.8.1

$$\sigma_i(\mathbf{A}-\mathbf{A}_k) = \sigma_{k+i}(\mathbf{A}) \qquad (1\le i\le p), \tag{20.6.1}$$

with the convention $\sigma_j(\mathbf{A}) = 0$ for **every** $j > p$. Chapter 16 §09 states it for $p < j \le n$; we extend it here, because the indices $k+i$ above run as far as $2p$, which may exceed n.

The competitor. Let $\operatorname{rank}\mathbf{B} \le k$. Then $\sigma_{k+1}(\mathbf{B}) = 0$, since a matrix has exactly $\operatorname{rank}\mathbf{B}$ non-zero singular values (Theorem 12.8.1). Fix $i \le p$. If $i+k > n$, then $\sigma_{k+i}(\mathbf{A}) = 0 \le \sigma_i(\mathbf{A}-\mathbf{B})$ by the convention. Otherwise $i+(k+1)-1 = i+k \le n$, so Theorem 16.9.4 applies to the sum $\mathbf{A} = (\mathbf{A}-\mathbf{B})+\mathbf{B}$ with indices i and $k+1$ and gives

$$\sigma_{k+i}(\mathbf{A}) \;\le\; \sigma_i(\mathbf{A}-\mathbf{B}) + \sigma_{k+1}(\mathbf{B}) = \sigma_i(\mathbf{A}-\mathbf{B}).$$

Either way, with Eq. 20.6.1,

$$\sigma_i(\mathbf{A}-\mathbf{A}_k) \;\le\; \sigma_i(\mathbf{A}-\mathbf{B}) \qquad (1\le i\le p).$$

Summing the first k' of these for each $k' \le p$ gives $\sigma(\mathbf{A}-\mathbf{A}_k) \prec_w \sigma(\mathbf{A}-\mathbf{B})$, so Theorem 20.6.1 gives $\|\mathbf{A}-\mathbf{A}_k\| \le \|\mathbf{A}-\mathbf{B}\|$ for every unitarily invariant norm.

The value. By Theorem 20.4.3 and Eq. 20.6.1, $\|\mathbf{A}-\mathbf{A}_k\| = \Phi(\sigma(\mathbf{A}-\mathbf{A}_k)) = \Phi(\sigma_{k+1},\dots,\sigma_p,0,\dots,0)$. This proves the corollary. ∎

The proof gives more than was asked: the error of the truncation is smaller than that of any competitor **singular value by singular value**, not merely in every norm. Specializing Φ recovers the two known cases — $\Phi = \|\cdot\|_\infty$ gives σ_{k+1}, which is Theorem 16.9.6, and $\Phi = \|\cdot\|_2$

gives $(\sum_{i>k}\sigma_i^2)^{1/2}$, which is Theorem 12.10.3 — and now every other norm comes with them.

Example. (One matrix, four norms)

Let

$$\mathbf{A} = \begin{pmatrix} 6 & -4 & 0 \\ 8 & 3 & 0 \\ 0 & 0 & 1 \end{pmatrix} \in M_3(\mathbb{R}).$$

Find $\mathbf{A}_1$ and $\mathbf{A}_2$, and tabulate the approximation errors in the spectral, Frobenius, trace and Ky Fan 2-norms. Compare $\mathbf{A}_1$ with the rank-one competitor $\mathbf{C} = \operatorname{diag}(0,0,1)$.

Solution. Write $\mathbf{Q} = \frac{1}{5}\begin{pmatrix} 3 & -4 & 0 \\ 4 & 3 & 0 \\ 0 & 0 & 5 \end{pmatrix}$, which is orthogonal, since its columns are orthonormal. Then $\mathbf{A} = \mathbf{Q}\operatorname{diag}(10,5,1)$, so this is a singular value decomposition with $\mathbf{U} = \mathbf{Q}$, $\mathbf{V} = \mathbf{I}$, and $\sigma(\mathbf{A}) = (10,5,1)$. Hence

$$\mathbf{A}_1 = \begin{pmatrix} 6 & 0 & 0 \\ 8 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \qquad \mathbf{A}_2 = \begin{pmatrix} 6 & -4 & 0 \\ 8 & 3 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

with errors $\mathbf{A} - \mathbf{A}_1 = \mathbf{Q}\operatorname{diag}(0,5,1)$ and $\mathbf{A} - \mathbf{A}_2 = \mathbf{Q}\operatorname{diag}(0,0,1)$, whose singular value lists are $(5,1,0)$ and $(1,0,0)$, as Eq. 20.6.1 predicts.

error measured in	$\mathbf{A} - \mathbf{A}_1$	$\mathbf{A} - \mathbf{A}_2$	$\mathbf{A} - \mathbf{C}$
spectral $\|\cdot\|_2$	5	1	10
Frobenius $\|\cdot\|_F$	$\sqrt{26}$	1	$\sqrt{125}$
trace norm	6	1	15
Ky Fan 2-norm (Definition 20.4.2)	6	1	15

The competitor $\mathbf{C} = \operatorname{diag}(0,0,1)$ has rank 1, and $\mathbf{A} - \mathbf{C} = \mathbf{A}_2 = \mathbf{Q}\operatorname{diag}(10,5,0)$ has singular values $(10,5,0)$. It loses to $\mathbf{A}_1$ in all four norms at once, as it must: $(5,1,0)$ is dominated entry by entry by $(10,5,0)$. Note also that the Ky Fan 2-norm and the trace norm agree on these three errors, because each has at most two non-zero singular values.

20.6.3 The nearest unitary matrix

Chapter 12 §09 proved that the unitary polar factor $\mathbf{W}$ of $\mathbf{A} = \mathbf{W}|\mathbf{A}|$ is the nearest unitary matrix in the Frobenius norm (Corollary 12.9.2) and warned: "It is true, though not proved here, that $\mathbf{W}$ also minimizes the distance in every unitarily invariant norm; Chapter 20 takes up that family of norms." That is this corollary.

The proof passes through a symmetric list of the form $(z_1, \dots, z_q, 0, \dots, 0, -z_q, \dots, -z_1)$, and has to read off its top-k sums. Section 7 meets the same list again, so we settle the counting once.

Lemma 20.6.3 — Top Sums of a Symmetric List

Let $z_1, \dots, z_q$ be real numbers, let $r \geq 0$ be an integer, and let $\mathbf{c} \in \mathbb{R}^{2q+r}$ be the list

$$\mathbf{c} = \big(z_1, \dots, z_q,\ \underbrace{0, \dots, 0}_{r},\ -z_q, \dots, -z_1\big).$$

Then for every $k \leq q$, the largest sum of k entries of $\mathbf{c}$, which is the running total $\sum_{j \leq k} c_j^{\downarrow}$, equals the sum of the k largest of the numbers $|z_1|, \dots, |z_q|$.

Proof. Fix $k \leq q$. Write S for the sum of the k largest of the $|z_i|$. Since the largest sum of k entries of $\mathbf{c}$ is obtained by taking the k largest entries, it is $\sum_{j \leq k} c_j^{\downarrow}$, and the two descriptions agree.

($\geq$) For each index i, the number $|z_i|$ is an entry of $\mathbf{c}$: it is z_i in position i if $z_i \geq 0$, and $-z_i$ in position $2q + r + 1 - i$ otherwise. Distinct indices i give distinct positions, so the k largest of the $|z_i|$ occur at k distinct positions of $\mathbf{c}$, and their sum S is one of the sums being maximized.

($\leq$) Let k positions be given. The entries in the middle range contribute 0, and the remaining positions belong to at most k of the indices i. For one such index, the chosen positions contribute z_i, or $-z_i$, or (if both are chosen) 0, hence at most $|z_i|$ in every case. So the sum of the chosen entries is at most $\sum_{i \in J} |z_i|$ for a set J of at most k indices, and since every $|z_i| \geq 0$ that is at most S. This proves the lemma.

■

Corollary 20.6.4 — The Polar Factor Is Nearest in Every Unitarily Invariant Norm

Let $\mathbf{A} \in M_n(\mathbb{C})$ with polar decomposition $\mathbf{A} = \mathbf{W}|\mathbf{A}|$ (Theorem 12.9.1). Then for every unitary $\mathbf{Q} \in M_n(\mathbb{C})$ and every unitarily invariant norm on $M_n(\mathbb{C})$,

$$\|\mathbf{A} - \mathbf{W}\| \ \leq\ \|\mathbf{A} - \mathbf{Q}\|.$$

Idea. Peel off $\mathbf{W}$. Unitary invariance turns the comparison of $\mathbf{A} - \mathbf{Q}$ with $\mathbf{A} - \mathbf{W}$ into a comparison of $|\mathbf{A}| - \mathbf{U}$ with $|\mathbf{A}| - \mathbf{I}$, where $\mathbf{U} = \mathbf{W}^*\mathbf{Q}$ runs over all unitary matrices: the question is why the identity is the unitary matrix closest to a positive semidefinite one. By dominance it is enough to weakly majorize singular values, and singular values of a difference of two matrices are eigenvalues of a difference of two Hermitian ones, through the dilation of Chapter 16 §09. There, Lidskii's theorem is waiting: it already says that the vector of eigenvalue shifts is majorized by the eigenvalues of the difference, and choosing the right k entries of that majorization is the whole computation.

Proof. **Step 1: reduce to $|\mathbf{A}|$ and $\mathbf{I}$.** Let $\mathbf{Q}$ be unitary and put $\mathbf{U} := \mathbf{W}^*\mathbf{Q}$, which is unitary. Then

$$\mathbf{A} - \mathbf{Q} = \mathbf{W}|\mathbf{A}| - \mathbf{Q} = \mathbf{W}\big(|\mathbf{A}| - \mathbf{W}^*\mathbf{Q}\big) = \mathbf{W}(|\mathbf{A}| - \mathbf{U}),$$

so $\|\mathbf{A} - \mathbf{Q}\| = \||\mathbf{A}| - \mathbf{U}\|$ by unitary invariance (Definition 20.4.1). Taking $\mathbf{Q} = \mathbf{W}$ gives $\mathbf{U} = \mathbf{I}$ and $\|\mathbf{A} - \mathbf{W}\| = \||\mathbf{A}| - \mathbf{I}\|$. Writing $\mathbf{S} = |\mathbf{A}| \succeq 0$, it suffices to prove

$$\|\mathbf{S} - \mathbf{I}\| \leq \|\mathbf{S} - \mathbf{U}\| \qquad \text{for every unitary } \mathbf{U}.$$

By Theorem 20.6.1 this is the weak majorization $\sigma(\mathbf{S}-\mathbf{I}) \prec_w \sigma(\mathbf{S}-\mathbf{U})$.

Step 2: the singular values of $\mathbf{S}-\mathbf{I}$. Let $t_1 \geq \cdots \geq t_n \geq 0$ be the eigenvalues of $\mathbf{S}$, which are non-negative because $\mathbf{S} \succeq 0$ (Theorem 12.1.4). The spectral theorem writes $\mathbf{S} = \mathbf{Y}\,\mathrm{diag}(t_1,\dots,t_n)\mathbf{Y}^*$ with $\mathbf{Y}$ unitary, and this is a singular value decomposition, so $\sigma_i(\mathbf{S}) = t_i$. The matrix $\mathbf{S}-\mathbf{I}$ is Hermitian with eigenvalues $t_i - 1$, and $(\mathbf{S}-\mathbf{I})^*(\mathbf{S}-\mathbf{I}) = (\mathbf{S}-\mathbf{I})^2$ has eigenvalues $(t_i-1)^2$, so by Definition 12.8.1

$$\sigma(\mathbf{S}-\mathbf{I}) = \big(|t_1-1|,\dots,|t_n-1|\big)^{\downarrow}.$$

Write $s_j = \sigma_j(\mathbf{S}-\mathbf{U})$ for the numbers we must bound from below.

Step 3: dilate. Let $\mathcal{H}(\cdot)$ be the Hermitian dilation of Proposition 16.9.3. Conjugate transposition is additive, so $\mathcal{H}(\mathbf{S}) - \mathcal{H}(\mathbf{U}) = \mathcal{H}(\mathbf{S}-\mathbf{U})$, and all three are Hermitian matrices in $M_{2n}(\mathbb{C})$. By Proposition 16.9.3, the eigenvalues of $\mathcal{H}(\mathbf{M})$ are $\pm\sigma_i(\mathbf{M})$, and since the σ_i are non-negative and decreasing, the decreasing list is

$$\boldsymbol{\lambda}(\mathcal{H}(\mathbf{M})) = \big(\sigma_1(\mathbf{M}),\dots,\sigma_n(\mathbf{M}),-\sigma_n(\mathbf{M}),\dots,-\sigma_1(\mathbf{M})\big).$$

Applied to $\mathbf{S}$, to $\mathbf{U}$ (all of whose singular values are 1) and to $\mathbf{S}-\mathbf{U}$, this gives the three lists

$$\begin{aligned}\boldsymbol{\lambda}(\mathcal{H}(\mathbf{S})) &= (t_1,\dots,t_n,-t_n,\dots,-t_1),\\ \boldsymbol{\lambda}(\mathcal{H}(\mathbf{U})) &= (1,\dots,1,-1,\dots,-1),\\ \boldsymbol{\lambda}(\mathcal{H}(\mathbf{S}-\mathbf{U})) &= (s_1,\dots,s_n,-s_n,\dots,-s_1).\end{aligned}$$

Step 4: apply Lidskii's theorem. Chapter 16 §07 proved, in the remark following Theorem 16.7.2, that $\boldsymbol{\lambda}(\mathbf{X}) - \boldsymbol{\lambda}(\mathbf{Y}) \prec \boldsymbol{\lambda}(\mathbf{X}-\mathbf{Y})$ for Hermitian $\mathbf{X},\mathbf{Y}$. Applied to $\mathbf{X} = \mathcal{H}(\mathbf{S})$ and $\mathbf{Y} = \mathcal{H}(\mathbf{U})$,

$$\boldsymbol{\lambda}(\mathcal{H}(\mathbf{S})) - \boldsymbol{\lambda}(\mathcal{H}(\mathbf{U})) \;\prec\; \boldsymbol{\lambda}(\mathcal{H}(\mathbf{S}-\mathbf{U})).$$

By Step 3 the vector on the left is

$$\mathbf{d} = \big(t_1-1,\dots,t_n-1,\;-(t_n-1),\dots,-(t_1-1)\big) \in \mathbb{R}^{2n},$$

which is the symmetric list of Lemma 20.6.3 with $q=n$, $r=0$ and $z_i = t_i - 1$. Fix $k \leq n$. By that lemma the k-th running total of $\mathbf{d}^{\downarrow}$ is the sum of the k largest of the numbers $|t_i-1|$, which by Step 2 is $\sum_{j\leq k}\sigma_j(\mathbf{S}-\mathbf{I})$. The right-hand list is decreasing with non-negative first half, so its k-th running total is $\sum_{j\leq k} s_j$. So (M1) of Definition 16.8.1, at the index k, reads

$$\sum_{j=1}^{k}\sigma_j(\mathbf{S}-\mathbf{I}) \;\leq\; \sum_{j=1}^{k}\sigma_j(\mathbf{S}-\mathbf{U}).$$

As this holds for every $k \leq n$, it is the weak majorization required in Step 1. This proves the corollary.

■

The mechanism deserves a name, because Section 7 runs it again in general: **a Hermitian dilation turns a statement about singular values into one about eigenvalues**, where Lidskii's theorem applies. What was special here is that both matrices were **square**, so that their dilations had no zeros in the middle of the spectrum and no bookkeeping was needed; that one of the two was unitary is what made its dilated eigenvalue list the constant ± 1.

Remark. The inequality of Corollary 20.6.4 cannot be improved to $\sigma_j(\mathbf{A}-\mathbf{W}) \le \sigma_j(\mathbf{A}-\mathbf{Q})$ index by index. Take $\mathbf{A} = \mathbf{S} = \operatorname{diag}(2,0)$, which is positive semidefinite, so that $|\mathbf{A}| = \mathbf{A}$ and $\mathbf{W} = \mathbf{I}$ is a polar factor, and take $\mathbf{Q} = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$. Then the matrix $\mathbf{S}-\mathbf{Q} = \left(\begin{smallmatrix} 2 & -1 \\ -1 & 0 \end{smallmatrix}\right)$ is symmetric with eigenvalues $1 \pm \sqrt{2}$, so $\sigma(\mathbf{S}-\mathbf{Q}) = (1+\sqrt{2}, \sqrt{2}-1) \approx (2.414, 0.414)$, while $\sigma(\mathbf{S}-\mathbf{I}) = (1,1)$. The second singular value is smaller for $\mathbf{Q}$, and only the running totals, $1 \le 2.414$ and $2 \le 2.828$, go the right way. So the weak majorization, and not something cruder, is what the corollary needs.

20.6.4 Two smaller consequences

A compression never increases a unitarily invariant norm.

Corollary 20.6.5 — Compressions Are Contractions

Let $\mathbf{A} \in M_n(F)$ and let $\mathbf{P} \in M_n(F)$ be an orthogonal projection. Then $|||\mathbf{PAP}||| \le |||\mathbf{A}|||$ for every unitarily invariant norm.

Proof. If $\mathbf{P} = \mathbf{0}$ the left side is $|||\mathbf{0}||| = 0 \le |||\mathbf{A}|||$. Otherwise $\mathbf{P}$ is Hermitian with eigenvalues in $\{0,1\}$, at least one of them equal to 1, so $\|\mathbf{P}\|_2 = 1$ by Lemma 16.3.5. Applying the two bounds of Proposition 20.4.4 (b) in turn,

$$|||\mathbf{PAP}||| \le \|\mathbf{P}\|_2 \, |||\mathbf{AP}||| \le \|\mathbf{P}\|_2 \, |||\mathbf{A}||| \, \|\mathbf{P}\|_2 = |||\mathbf{A}|||,$$

as claimed. ∎

And a negative result, about the subadditivity of singular values. Section 4 proved $\sigma(\mathbf{A}+\mathbf{B}) \prec_w \sigma(\mathbf{A}) + \sigma(\mathbf{B})$ (Lemma 20.4.2), where the right-hand side is the entrywise sum of the two decreasing lists. The weak majorization cannot be upgraded to majorization.

Example. (Weak majorization is the most that holds)

Let $\mathbf{A} = \operatorname{diag}(1,0)$ and $\mathbf{B} = \operatorname{diag}(-1,0)$. Then $\sigma(\mathbf{A}) = \sigma(\mathbf{B}) = (1,0)$, so $\sigma(\mathbf{A}) + \sigma(\mathbf{B}) = (2,0)$, while $\mathbf{A}+\mathbf{B} = \mathbf{0}$ has $\sigma(\mathbf{A}+\mathbf{B}) = (0,0)$. The totals are 0 and 2, so $\sigma(\mathbf{A}+\mathbf{B}) \prec \sigma(\mathbf{A}) + \sigma(\mathbf{B})$ is false, although the weak majorization holds with room to spare.

The failure is not an accident of the example. Take $\mathbf{B} = -\mathbf{A}$ for any $\mathbf{A} \neq \mathbf{0}$: then $\sigma(\mathbf{B}) = \sigma(\mathbf{A})$, so the right-hand list has total $2\sum_i \sigma_i(\mathbf{A}) > 0$, while $\sigma(\mathbf{A}+\mathbf{B}) = \mathbf{0}$ has total 0. Cancellation destroys singular value mass, and clause (M2) of Definition 16.8.1 — equal totals — therefore fails for every non-zero $\mathbf{A}$. Weak majorization is the most Lemma 20.4.2 can assert.

20.6.5 Exercises

20.6.5.1 A. Check your understanding

Exercise A1.

(a) State Theorem 20.6.1, and say which family of norms proves the direction that is not a direct consequence of Sections 3 and 4.

(b) Define the Ky Fan k-norm and say why it is a unitarily invariant norm.

(c) Determine whether the following is true, and justify your answer: if $\|\mathbf{A}\|_F \le \|\mathbf{B}\|_F$ and $\|\mathbf{A}\|_2 \le \|\mathbf{B}\|_2$, then $|||\mathbf{A}||| \le |||\mathbf{B}|||$ for every unitarily invariant norm.

(d) In the proof of Corollary 20.6.2, where is the hypothesis $\operatorname{rank}\mathbf{B} \le k$ used?

(e) Determine whether the following is true, and justify your answer: for $\mathbf{A} \in M_n(\mathbb{C})$ invertible, the nearest unitary matrix in the trace norm is the same as the nearest one in the Frobenius norm.

Solution.

(a) For $\mathbf{A}, \mathbf{B}$ of the same size, $\sigma(\mathbf{A}) \prec_w \sigma(\mathbf{B})$ if and only if $|||\mathbf{A}||| \le |||\mathbf{B}|||$ for every unitarily invariant norm. The direction (b) $\Rightarrow$ (a) is the one needing new input, and it is proved by applying the hypothesis to the Ky Fan k-norms.

(b) $|||\mathbf{M}|||_{(k)} = \sum_{i \le k} \sigma_i(\mathbf{M})$ (Definition 20.4.2). It is the unitarily invariant norm attached by Theorem 20.4.3 to the k-th Ky Fan gauge Definition 20.3.2, evaluated at $\sigma(\mathbf{M})$.

(c) False. Two norms do not decide the family. Take $\mathbf{A} = \operatorname{diag}(1,1,0)$ and $\mathbf{B} = \operatorname{diag}(\sqrt{2},0,0)$: then $\|\mathbf{A}\|_F = \sqrt{2} = \|\mathbf{B}\|_F$ and $\|\mathbf{A}\|_2 = 1 \le \sqrt{2} = \|\mathbf{B}\|_2$, but the trace norms are 2 and $\sqrt{2}$, so $|||\mathbf{A}||| \le |||\mathbf{B}|||$ fails for the trace norm.

(d) Only to give $\sigma_{k+1}(\mathbf{B}) = 0$, which is what makes the Weyl inequality with second index $k+1$ say something about $\mathbf{A} - \mathbf{B}$ alone.

(e) False: in the trace norm the minimizer need not be unique, so there is no *the* nearest unitary matrix. The polar factor $\mathbf{W}$ is nearest in both norms, by Corollary 20.6.4, and for invertible $\mathbf{A}$ it is the **only** Frobenius minimizer (Corollary 12.9.2); in the trace norm it can share the minimum. Take $\mathbf{A} = \operatorname{diag}(2, \tfrac{1}{2})$, which is positive definite, so $|\mathbf{A}| = \mathbf{A}$ and $\mathbf{W} = \mathbf{I}$. Then $\mathbf{A} - \mathbf{I} = \operatorname{diag}(1, -\tfrac{1}{2})$ has trace norm $\tfrac{3}{2}$. The rotation $\mathbf{Q} = \tfrac{1}{5}\left(\begin{smallmatrix} 4 & -3 \\ 3 & 4 \end{smallmatrix}\right)$ is unitary, and

$$\mathbf{A} - \mathbf{Q} = \tfrac{1}{10}\begin{pmatrix} 12 & 6 \\ -6 & -3 \end{pmatrix}$$

has determinant 0 and is non-zero, so it has rank 1: its second singular value is 0, and the first is $\|\mathbf{A}-\mathbf{Q}\|_F = \tfrac{1}{10}\sqrt{144+36+36+9} = \tfrac{3}{2}$. Its trace norm is therefore $\tfrac{3}{2}$ as well, so $\mathbf{I}$ and $\mathbf{Q}$ are both nearest in the trace norm. In the Frobenius norm they are not tied: $\|\mathbf{A} - \mathbf{I}\|_F = \tfrac{\sqrt{5}}{2} < \tfrac{3}{2} = \|\mathbf{A} - \mathbf{Q}\|_F$.

20.6.5.2 B. Practice

Exercise B1: Dominance by hand.

Let $\mathbf{A}, \mathbf{B} \in M_3(\mathbb{R})$ have singular values $\sigma(\mathbf{A}) = (3,2,2)$ and $\sigma(\mathbf{B}) = (4,3,1)$.

(a) Determine whether $|||\mathbf{A}||| \le |||\mathbf{B}|||$ for every unitarily invariant norm.

(b) Answer the same question for $\sigma(\mathbf{A}') = (3,3,2)$ in place of $\sigma(\mathbf{A})$.

Solution.

(a) The running totals are $3, 5, 7$ for $\mathbf{A}$ and $4, 7, 8$ for $\mathbf{B}$, and $3 \le 4$, $5 \le 7$, $7 \le 8$. So $\sigma(\mathbf{A}) \prec_w \sigma(\mathbf{B})$ and Theorem 20.6.1 gives the inequality for every unitarily invariant norm.

(b) The running totals of $\sigma(\mathbf{A}')$ are $3, 6, 8$, all at most $4, 7, 8$, so again yes. This one is worth noticing, because the index-by-index comparison **fails**: $\sigma_3(\mathbf{A}') = 2 > 1 = \sigma_3(\mathbf{B})$. Dominance is a statement about running totals, and it is strictly weaker than entrywise domination.

Exercise B2: Best approximations of a 2 by 2 matrix.

Let $\mathbf{A} = \left(\begin{smallmatrix} 3 & 4 \\ 4 & -3 \end{smallmatrix}\right)$. Compute $\sigma(\mathbf{A})$, find the best rank-one approximation, and compute the error in the spectral, Frobenius and trace norms. What is unusual about this matrix?

Solution. $\mathbf{A}^\top \mathbf{A} = \left(\begin{smallmatrix} 25 & 0 \\ 0 & 25 \end{smallmatrix}\right)$, so $\sigma(\mathbf{A}) = (5, 5)$. By Corollary 20.6.2 the best rank-one approximation is $\mathbf{A}_1 = 5\mathbf{u}_1\mathbf{v}_1^*$ for a singular value decomposition of $\mathbf{A}$. One such decomposition is $\mathbf{A} = \mathbf{U}\operatorname{diag}(5, 5)\mathbf{V}^\top$ with $\mathbf{V} = \mathbf{I}$ and $\mathbf{U} = \mathbf{A}/5$, which is orthogonal because $\mathbf{A}^\top \mathbf{A} = 25\mathbf{I}$; it gives $\mathbf{u}_1 = \frac{1}{5}(3, 4)$, $\mathbf{v}_1 = \mathbf{e}_1$ and

$$\mathbf{A}_1 = \begin{pmatrix} 3 & 0 \\ 4 & 0 \end{pmatrix}, \qquad \mathbf{A} - \mathbf{A}_1 = \begin{pmatrix} 0 & 4 \\ 0 & -3 \end{pmatrix}.$$

The error has singular values $(\sigma_2, 0) = (5, 0)$, as Corollary 20.6.2 predicts: spectral error 5, Frobenius error 5, trace-norm error 5. What is unusual is that $\sigma_1 = \sigma_2$, so the truncation is not unique: $\mathbf{A}/5$ is symmetric and orthogonal, and **every** unit vector is a right singular vector. Every rank-one matrix of the form $5\mathbf{u}\mathbf{v}^*$ arising from a singular value decomposition is a best approximation, and they are genuinely different matrices.

Exercise B3: A compression.

Let $\mathbf{A} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 3 \end{smallmatrix}\right)$ and let $\mathbf{P} = \mathbf{e}_1\mathbf{e}_1^\top$. Compute $|||\mathbf{PAP}|||$ and $|||\mathbf{A}|||$ for the trace norm, and check Corollary 20.6.5.

Solution. $\mathbf{PAP} = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, whose singular values are $(2, 0)$, so its trace norm is 2. The matrix $\mathbf{A}$ is symmetric with $\operatorname{tr}\mathbf{A} = 5$ and $\det\mathbf{A} = 5$, so its eigenvalues are $(5 \pm \sqrt{5})/2$, both positive; hence $\mathbf{A} \succ 0$, its singular values are its eigenvalues, and its trace norm is $\operatorname{tr}\mathbf{A} = 5$. Indeed $2 \le 5$.

20.6.5.3 C. Going deeper

Exercise C1: Dominance for sums.

Let $\mathbf{A}, \mathbf{B} \in M_{m\times n}(\mathbb{C})$.

(a) Prove that $|||\mathbf{A}+\mathbf{B}||| \le |||\mathbf{A}||| + |||\mathbf{B}|||$ follows from Lemma 20.4.2 together with Theorem 20.3.4 (b), without using that $|||\cdot|||$ is a norm.

(b) Deduce that $\sum_{i\le k}\sigma_i(\mathbf{A}+\mathbf{B}) \le \sum_{i\le k}\sigma_i(\mathbf{A}) + \sum_{i\le k}\sigma_i(\mathbf{B})$ for every k.

Solution.

(a) By Lemma 20.4.2, $\sigma(\mathbf{A}+\mathbf{B}) \prec_w \sigma(\mathbf{A})+\sigma(\mathbf{B})$, and all three vectors have non-negative entries. Let Φ be the gauge of the norm. By Theorem 20.3.4 (b), $\Phi(\sigma(\mathbf{A}+\mathbf{B})) \le \Phi(\sigma(\mathbf{A})+\sigma(\mathbf{B}))$, and by the triangle inequality for the norm Φ on $\mathbb{R}^p$ the right side is at most $\Phi(\sigma(\mathbf{A}))+\Phi(\sigma(\mathbf{B}))$. By Theorem 20.4.3 these are $|||\mathbf{A}+\mathbf{B}|||$, and $|||\mathbf{A}|||+|||\mathbf{B}|||$. (The triangle inequality used is that of Φ, a norm on $\mathbb{R}^p$, not that of $|||\cdot|||$.)

(b) Apply (a) to the Ky Fan k-norm, whose value at $\mathbf{M}$ is $\sum_{i\le k}\sigma_i(\mathbf{M})$.

Exercise C2: Distance to the singular matrices, in every norm.

Let $\mathbf{A} \in M_n(\mathbb{C})$ be invertible with singular values $\sigma_1 \ge \cdots \ge \sigma_n > 0$, and let $|||\cdot|||$ be a unitarily invariant norm with gauge Φ.

(a) Prove that $\min\{|||\mathbf{A}-\mathbf{B}||| : \mathbf{B} \in M_n(\mathbb{C}) \text{ singular}\} = \Phi(\sigma_n, 0, \dots, 0)$.

(b) Deduce that this minimum equals $\sigma_n\,\Phi(\mathbf{e}_1)$, and identify it for the spectral, Frobenius and trace norms.

Hint: a matrix is singular exactly when its rank is at most $n-1$.

Solution.

(a) By Theorem 6.5.3 (d), $\mathbf{B}$ is singular if and only if $\operatorname{rank}\mathbf{B} \le n-1$. So the minimum is over the set appearing in Corollary 20.6.2 with $k = n-1$, and that corollary gives the value $\Phi(\sigma_n, 0, \dots, 0)$, attained at the truncation $\mathbf{A}_{n-1}$, which is singular because its rank is $n-1$.

(b) The vector $(\sigma_n, 0, \dots, 0)$ is $\sigma_n\mathbf{e}_1$, and Φ is a norm, so $\Phi(\sigma_n\mathbf{e}_1) = \sigma_n\Phi(\mathbf{e}_1)$ as $\sigma_n > 0$. For the spectral norm $\Phi = \|\cdot\|_\infty$ and $\Phi(\mathbf{e}_1) = 1$; for the Frobenius norm $\Phi = \|\cdot\|_2$ and $\Phi(\mathbf{e}_1) = 1$; for the trace norm $\Phi = \|\cdot\|_1$ and $\Phi(\mathbf{e}_1) = 1$. All three give σ_n. This is not an accident: the normalization $\Phi(\mathbf{e}_1) = 1$ of Section 4 is exactly the condition that makes every unitarily invariant norm agree on rank-one matrices with one non-zero singular value.

Exercise C3: Unitary matrices are far apart.

Let $\mathbf{U}, \mathbf{Q} \in M_n(\mathbb{C})$ be unitary with $\mathbf{U} \ne \mathbf{Q}$.

(a) Prove that $\sigma(\mathbf{U}-\mathbf{Q}) = (|\mu_1-1|, \dots, |\mu_n-1|)^{\downarrow}$, where $\mu_1, \dots, \mu_n$ are the eigenvalues of $\mathbf{Q}^*\mathbf{U}$.

(b) Deduce that $|||\mathbf{U}-\mathbf{Q}||| = |||\operatorname{diag}(\mu_1-1, \dots, \mu_n-1)|||$ for every unitarily invariant norm, and that the trace-norm distance between two distinct unitary matrices can be as large as $2n$.

Solution.

(a) $\mathbf{U}-\mathbf{Q} = \mathbf{Q}(\mathbf{Q}^*\mathbf{U}-\mathbf{I})$, and multiplying on the left by a unitary matrix does not change singular values, since $(\mathbf{QM})^*(\mathbf{QM}) = \mathbf{M}^*\mathbf{M}$ (Definition 12.8.1). The matrix $\mathbf{Z} \coloneqq \mathbf{Q}^*\mathbf{U}$ is unitary, hence normal, so by the spectral theorem $\mathbf{Z} =$

$\mathbf{Y}\,\mathrm{diag}(\mu_1,\dots,\mu_n)\mathbf{Y}^*$ with $\mathbf{Y}$ unitary, and $\mathbf{Z}-\mathbf{I}=\mathbf{Y}\,\mathrm{diag}(\mu_i-1)\mathbf{Y}^*$. Then $(\mathbf{Z}-\mathbf{I})^*(\mathbf{Z}-\mathbf{I})=\mathbf{Y}\,\mathrm{diag}(|\mu_i-1|^2)\mathbf{Y}^*$, so the singular values are the numbers $|\mu_i-1|$ sorted decreasingly (Definition 12.8.1).

(b) Both matrices in the claimed equality have the same singular value list, so Theorem 20.4.3 gives equal norms. Each μ_i has modulus 1, so $|\mu_i-1|\le 2$, with equality when $\mu_i=-1$. Taking $\mathbf{Q}=\mathbf{I}$ and $\mathbf{U}=-\mathbf{I}$ gives every $\mu_i=-1$ and trace-norm distance $\sum_i 2=2n$.

20.7 Lidskii's Theorem in Majorization Form

Chapter 16 §07 proved Lidskii's inequality and then translated the whole family of inequalities into one majorization. It could go no further, and said so. This section spends what it banked: the majorization is already in hand, and Sections 2, 3 and 6 turn it into a statement about every convex function and every unitarily invariant norm. The last part of the section carries all of it across to singular values.

20.7.1 What Chapter 16 proved, and what it left

Here is the statement we start from. For Hermitian $\mathbf{A},\mathbf{B}\in M_n(F)$, Theorem 16.7.2 says that for every index set $1\le i_1<\cdots<i_k\le n$,

$$\sum_{j=1}^{k}\lambda_{i_j}(\mathbf{A})-\sum_{j=1}^{k}\lambda_{i_j}(\mathbf{B})\ \le\ \sum_{j=1}^{k}\lambda_j(\mathbf{A}-\mathbf{B}),$$

and the remark that closes that section observes that, since the largest k entries of a vector are the best choice of k of them, this family of inequalities is exactly clause (M1) of Definition 16.8.1 for the pair of vectors below, while clause (M2) is the identity $\mathrm{tr}\,\mathbf{A}-\mathrm{tr}\,\mathbf{B}=\mathrm{tr}(\mathbf{A}-\mathbf{B})$:

$$\boldsymbol{\lambda}(\mathbf{A})-\boldsymbol{\lambda}(\mathbf{B})\ \prec\ \boldsymbol{\lambda}(\mathbf{A}-\mathbf{B}). \tag{20.7.1}$$

This is proved, in Chapter 16, and we do not prove it again. What Chapter 16 could not do it named exactly: "Not proved here, and left to Chapter 20: the general consequences of a majorization $\mathbf{x}\prec\mathbf{y}$, namely $\sum_i\phi(x_i)\le\sum_i\phi(y_i)$ for every convex $\phi\colon\mathbb{R}\to\mathbb{R}$, together with the matching statement for the unitarily invariant norms of that chapter."

Both consequences now exist. Section 2 proved the first, as Theorem 20.2.1. Section 3 proved that a symmetric gauge is monotone under majorization, as Theorem 20.3.4, and Section 4 identified the gauges with the unitarily invariant norms. All that is left is to apply them, which takes two short proofs, and then to repeat the exercise for singular values, which takes one idea.

Example. (A pair to keep in mind)

Let

$$\mathbf{A}=\begin{pmatrix}2&2\\2&2\end{pmatrix},\qquad \mathbf{B}=\begin{pmatrix}0&-1\\-1&0\end{pmatrix}.$$

Compute the three eigenvalue lists and check Eq. 20.7.1.

Solution. $\mathbf{A}$ is symmetric with $\operatorname{tr}\mathbf{A} = 4$ and $\det\mathbf{A} = 0$, so $\boldsymbol{\lambda}(\mathbf{A}) = (4, 0)$. $\mathbf{B}$ is symmetric with $\operatorname{tr}\mathbf{B} = 0$ and $\det\mathbf{B} = -1$, so $\boldsymbol{\lambda}(\mathbf{B}) = (1, -1)$. Their difference

$$\mathbf{A} - \mathbf{B} = \begin{pmatrix} 2 & 3 \\ 3 & 2 \end{pmatrix}$$

has trace 4 and determinant $4 - 9 = -5$, so $\boldsymbol{\lambda}(\mathbf{A} - \mathbf{B}) = (5, -1)$.

The vector of shifts is $\boldsymbol{\lambda}(\mathbf{A}) - \boldsymbol{\lambda}(\mathbf{B}) = (4 - 1,\ 0 - (-1)) = (3, 1)$, already decreasing. Now compare with $(5, -1)$: the top sums are $3 \le 5$, and the totals are $4 = 4$. So $(3, 1) \prec (5, -1)$, as Eq. 20.7.1 promises, and the majorization is strict in its one non-trivial inequality.

20.7.2 Every convex function at once

Theorem 20.7.1 — Lidskii's Theorem, Convex Form

Let $\mathbf{A}, \mathbf{B} \in M_n(F)$ be Hermitian, $F = \mathbb{R}$ or $\mathbb{C}$. Then for every convex $\phi\colon \mathbb{R} \to \mathbb{R}$,

$$\sum_{i=1}^{n} \phi\big(\lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})\big) \ \le\ \sum_{i=1}^{n} \phi\big(\lambda_i(\mathbf{A} - \mathbf{B})\big).$$

Proof. By Eq. 20.7.1, $\boldsymbol{\lambda}(\mathbf{A}) - \boldsymbol{\lambda}(\mathbf{B}) \prec \boldsymbol{\lambda}(\mathbf{A} - \mathbf{B})$. Apply Theorem 20.2.1 to this majorization, with $I = \mathbb{R}$ and the given ϕ. This proves the theorem. ∎

Three readings are worth having. With $\phi(t) = |t|$, which is convex, the theorem says that the total movement of the eigenvalues is at most the total size of the eigenvalues of the perturbation. With $\phi(t) = t^2$ it is the Hoffman–Wielandt inequality, as the next corollary spells out. With $\phi(t) = \max(t, 0)$ it says that the total **upward** movement of the eigenvalues is at most the total of the positive eigenvalues of the perturbation, and with $\phi(t) = e^{ct}$ it gives bounds no earlier chapter could have stated.

Warning. The left side pairs $\lambda_i(\mathbf{A})$ with $\lambda_i(\mathbf{B})$ at the **same index**, both lists being in decreasing order, and the theorem claims nothing about any other pairing. For $\mathbf{A} = \operatorname{diag}(4, 0)$ and $\mathbf{B} = \left(\begin{smallmatrix} 2 & 2 \\ 2 & 2 \end{smallmatrix}\right)$ the spectra are equal, $\boldsymbol{\lambda}(\mathbf{A}) = \boldsymbol{\lambda}(\mathbf{B}) = (4, 0)$, so the sorted pairing gives 0 with $\phi(t) = t^2$. The reversed pairing gives $(4-0)^2 + (0-4)^2 = 32$, while $\mathbf{A} - \mathbf{B} = \left(\begin{smallmatrix} 2 & -2 \\ -2 & -2 \end{smallmatrix}\right)$ has $\sum_i \lambda_i(\mathbf{A} - \mathbf{B})^2 = \|\mathbf{A} - \mathbf{B}\|_F^2 = 16$. So the same inequality with a different matching is simply false.

20.7.3 Every unitarily invariant norm at once

To state the norm version we need to put a vector of shifts inside a matrix, and Section 4 has already done it. By Lemma 20.4.1 the gauge of a unitarily invariant norm is recovered from the norm by

$$\|\!|\mathrm{diag}_{m,n}(\mathbf{x})|\!\| = \Phi(\mathbf{x}) \qquad (\mathbf{x} \in \mathbb{R}^p), \tag{20.7.2}$$

where $\mathrm{diag}_{m,n}(\mathbf{x})$ carries $\mathbf{x}$ down the main diagonal and zeros elsewhere, and is written $\mathrm{diag}(\mathbf{x})$ when $m = n$. One more reading will be used throughout: if $\mathbf{H} \in M_n(F)$ is Hermitian then $\mathbf{H}^*\mathbf{H} = \mathbf{H}^2$ has eigenvalues $\lambda_i(\mathbf{H})^2$, so $\sigma(\mathbf{H}) = |\boldsymbol{\lambda}(\mathbf{H})|^{\downarrow}$ by Definition 12.8.1, and hence $\|\!|\mathbf{H}|\!\| = \Phi(\sigma(\mathbf{H})) = \Phi(\boldsymbol{\lambda}(\mathbf{H}))$, the last step by the permutation and sign invariance of Definition 20.3.1.

Theorem 20.7.2 — Lidskii's Theorem, Norm Form

Let $\mathbf{A}, \mathbf{B} \in M_n(F)$ be Hermitian. Then for **every** unitarily invariant norm on $M_n(F)$,

$$\|\!|\mathrm{diag}\big(\boldsymbol{\lambda}(\mathbf{A}) - \boldsymbol{\lambda}(\mathbf{B})\big)|\!\| \;\le\; \|\!|\mathbf{A} - \mathbf{B}|\!\|\,.$$

Idea. Both sides are the same symmetric gauge evaluated at two real vectors: the vector of eigenvalue shifts on the left, the eigenvalue vector of $\mathbf{A} - \mathbf{B}$ on the right. Chapter 16 says the first is majorized by the second, and Section 3 says a symmetric gauge respects that.

Proof. Let Φ be the symmetric gauge of the norm, so that $\|\!|\mathbf{M}|\!\| = \Phi(\sigma(\mathbf{M}))$ (Theorem 20.4.3). Put $\mathbf{x} = \boldsymbol{\lambda}(\mathbf{A}) - \boldsymbol{\lambda}(\mathbf{B})$ and $\mathbf{y} = \boldsymbol{\lambda}(\mathbf{A} - \mathbf{B})$, both in $\mathbb{R}^n$. By Eq. 20.7.2 the left-hand side is $\Phi(\mathbf{x})$; and since $\mathbf{A} - \mathbf{B}$ is Hermitian, the discussion above gives $\|\!|\mathbf{A} - \mathbf{B}|\!\| = \Phi(\mathbf{y})$. By Eq. 20.7.1, $\mathbf{x} \prec \mathbf{y}$, so Theorem 20.3.4 (a) — the part for arbitrary real vectors, which is what majorization rather than weak majorization buys — gives $\Phi(\mathbf{x}) \le \Phi(\mathbf{y})$. This proves the theorem. ∎

That is the second half of Chapter 16 §07's promise, and it is also what Chapter 19 §11 was waiting for when it listed, among the things that chapter did not do, that its bounds "hold in the Frobenius norm" and that "extending the eigenvalue and singular value bounds to every unitarily invariant norm belongs to Chapter 20". Two specializations make the point. With the spectral norm, whose gauge is $\|\cdot\|_\infty$, the theorem reads $\max_i |\lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})| \le \|\mathbf{A} - \mathbf{B}\|_2$, which is Weyl's perturbation bound Corollary 16.3.6. With the Frobenius norm, whose gauge is $\|\cdot\|_2$, it is Hoffman–Wielandt. One statement, two classical corollaries, and every norm in between.

Corollary 20.7.3 — Hoffman–Wielandt for Hermitian Matrices, Again

Let $\mathbf{A}, \mathbf{B} \in M_n(F)$ be Hermitian. Then

$$\sum_{i=1}^{n} \big(\lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})\big)^2 \;\le\; \|\mathbf{A} - \mathbf{B}\|_F^2.$$

Proof. The function $\phi(t) = t^2$ is convex, by Theorem 17.10.6 (a) with $\phi'' = 2 > 0$. By Theorem 20.7.1,

$$\sum_i \big(\lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})\big)^2 \le \sum_i \lambda_i(\mathbf{A} - \mathbf{B})^2.$$

The matrix $\mathbf{E} = \mathbf{A} - \mathbf{B}$ is Hermitian, so the spectral theorem writes $\mathbf{E} = \mathbf{U}\,\mathrm{diag}(\boldsymbol{\lambda}(\mathbf{E}))\mathbf{U}^*$

with $\mathbf{U}$ unitary, and Lemma 11.11.1 gives $\|\mathbf{E}\|_F^2 = \|\mathrm{diag}(\boldsymbol{\lambda}(\mathbf{E}))\|_F^2 = \sum_i \lambda_i(\mathbf{E})^2$. This proves the corollary.

■

This is Corollary 19.5.4 of Chapter 19 §05, reached by a different road. That section said so in advance: "Chapter 20 shows that a majorization $\mathbf{x} \prec \mathbf{y}$ gives $\sum_i \phi(x_i) \le \sum_i \phi(y_i)$ for every convex ϕ; with $\phi(t) = t^2$ this is Corollary 19.5.4 again, and Chapter 20 turns the same majorization into one bound for every unitarily invariant norm. Nothing here depends on that route; the proof above goes through Birkhoff's theorem . . . " So the two proofs are independent: Chapter 19 argued from Birkhoff's theorem applied to the matrix of squared moduli of the entries of a unitary change of basis, and never used Lidskii's inequality; this one uses Lidskii and never mentions doubly stochastic matrices. Neither is a special case of the other, and Chapter 19 reaches further in one direction: its Corollary 19.5.4 is the Hermitian case of Theorem 19.5.2, which holds for all **normal** $\mathbf{A}, \mathbf{B}$. What that theorem gives there is weaker in kind — some permutation matching the two eigenvalue lists, not the sorted one, since complex eigenvalues have no decreasing order — and the argument here, resting on Eq. 20.7.1, stays with Hermitian matrices throughout.

Quick check. Check Theorem 20.7.2 and Corollary 20.7.3 for the pair of Example (A pair to keep in mind), in the spectral, Frobenius and trace norms.

Solution. There $\boldsymbol{\lambda}(\mathbf{A}) - \boldsymbol{\lambda}(\mathbf{B}) = (3, 1)$ and $\boldsymbol{\lambda}(\mathbf{A} - \mathbf{B}) = (5, -1)$, so $\mathrm{diag}(3, 1)$ has singular values $(3, 1)$ and $\mathbf{A} - \mathbf{B}$ has singular values $(5, 1)$. The three norms of the left and right sides are: spectral, $3 \le 5$; Frobenius, $\sqrt{10} \le \sqrt{26}$; trace, $4 \le 6$. The Frobenius case squared is $9 + 1 = 10 \le 26$, which is Corollary 20.7.3.

20.7.4 The same theorem for singular values

Chapter 19 §10 proved Mirsky's theorem in the Frobenius norm and closed with: "Chapter 20 puts both inside one statement covering every unitarily invariant norm", the two being the index-by-index bound Corollary 16.9.5 and the Frobenius bound Theorem 19.10.1. The route is the one that section used and Section 6 used again: **a Hermitian dilation turns singular values into eigenvalues**, and then Lidskii's theorem applies. The only delicate point is the bookkeeping of the zeros, because a rectangular matrix dilates to a matrix with extra zero eigenvalues in the middle of its spectrum.

Theorem 20.7.4 — Mirsky's Theorem in Every Unitarily Invariant Norm

Let $\mathbf{A}, \mathbf{B} \in M_{m\times n}(\mathbb{C})$ and $p = \min(m, n)$. Then for **every** unitarily invariant norm on $M_{m\times n}(\mathbb{C})$,

$$\left\|\left|\mathrm{diag}_{m,n}\big(\sigma(\mathbf{A}) - \sigma(\mathbf{B})\big)\right|\right\| \;\le\; \left\|\left|\mathbf{A} - \mathbf{B}\right|\right\|.$$

Idea. Dilate all three matrices. The eigenvalue list of $\mathcal{H}(\mathbf{M})$ is $\sigma(\mathbf{M})$, then $m + n - 2p$ zeros, then $-\sigma(\mathbf{M})$ reversed, and the **positions** of the three blocks depend only on m and n — so $\mathbf{A}$ and $\mathbf{B}$ have their singular values in the same slots, and subtracting the two lists subtracts them index by index. Lidskii's majorization then compares a symmetric list $\pm(\sigma_i(\mathbf{A}) - \sigma_i(\mathbf{B}))$ with a symmetric list $\pm\sigma_j(\mathbf{A} - \mathbf{B})$ in $\mathbb{R}^{m+n}$. Reading its top-k

sums for $k \le p$ turns it into a weak majorization of the two lists we care about, in $\mathbb{R}^p$, and Section 3 finishes.

Proof. Write $N = m + n$, let $\delta_i = \sigma_i(\mathbf{A}) - \sigma_i(\mathbf{B})$ for $i \le p$ and $\boldsymbol{\delta} = (\delta_1, \dots, \delta_p)$, and let Φ be the symmetric gauge of the norm.

Step 1: what has to be proved. By Eq. 20.7.2 and the sign invariance of Definition 20.3.1, $\|\!|\mathrm{diag}_{m,n}(\boldsymbol{\delta})|\!\| = \Phi(\boldsymbol{\delta}) = \Phi(|\boldsymbol{\delta}|)$; and $\|\!|\mathbf{A} - \mathbf{B}|\!\| = \Phi(\sigma(\mathbf{A} - \mathbf{B}))$ by Theorem 20.4.3. Both $|\boldsymbol{\delta}|$ and $\sigma(\mathbf{A} - \mathbf{B})$ have non-negative entries, so by Theorem 20.3.4 (b) it is enough to prove the weak majorization

$$|\boldsymbol{\delta}| \;\prec_w\; \sigma(\mathbf{A} - \mathbf{B}) \qquad \text{in } \mathbb{R}^p. \tag{20.7.3}$$

Step 2: the dilations and their spectra. For $\mathbf{M} \in M_{m\times n}(\mathbb{C})$ let $\mathcal{H}(\mathbf{M}) = \left(\begin{smallmatrix} \mathbf{0} & \mathbf{M} \\ \mathbf{M}^* & \mathbf{0} \end{smallmatrix}\right) \in M_N(\mathbb{C})$ be the Hermitian dilation of Proposition 16.9.3. Conjugate transposition is additive, so

$$\mathcal{H}(\mathbf{A}) - \mathcal{H}(\mathbf{B}) = \mathcal{H}(\mathbf{A} - \mathbf{B}),$$

and all three matrices are Hermitian. By Proposition 16.9.3 the eigenvalues of $\mathcal{H}(\mathbf{M})$ are $\pm\sigma_1(\mathbf{M}), \dots, \pm\sigma_p(\mathbf{M})$ together with $N - 2p$ zeros; since the $\sigma_i(\mathbf{M})$ are non-negative and decreasing, the decreasing list is

$$\lambda_i(\mathcal{H}(\mathbf{M})) = \begin{cases} \sigma_i(\mathbf{M}) & 1 \le i \le p, \\ 0 & p < i \le N - p, \\ -\sigma_{N+1-i}(\mathbf{M}) & N - p < i \le N. \end{cases} \tag{20.7.4}$$

The three ranges depend only on m and n, so the formula applies to $\mathbf{A}$, to $\mathbf{B}$ and to $\mathbf{A} - \mathbf{B}$ **with the same ranges**. This is the bookkeeping the rectangular case needs: the zeros of $\mathcal{H}(\mathbf{A})$ sit in exactly the positions of the zeros of $\mathcal{H}(\mathbf{B})$, and so cancel when the two lists are subtracted.

Step 3: Lidskii. By Eq. 20.7.1 applied to the Hermitian pair $\mathcal{H}(\mathbf{A})$, $\mathcal{H}(\mathbf{B})$,

$$\boldsymbol{\lambda}(\mathcal{H}(\mathbf{A})) - \boldsymbol{\lambda}(\mathcal{H}(\mathbf{B})) \;\prec\; \boldsymbol{\lambda}(\mathcal{H}(\mathbf{A} - \mathbf{B})).$$

By Eq. 20.7.4 the vector on the left has entries δ_i in positions $i \le p$, zeros in the middle range, and $-\delta_{N+1-i}$ in the last p positions; the vector on the right has $\sigma_j(\mathbf{A} - \mathbf{B})$, zeros, and the negatives of the $\sigma_j(\mathbf{A} - \mathbf{B})$ in the same three ranges.

Step 4: read the running totals. Fix $k \le p$. The left-hand vector is the symmetric list of Lemma 20.6.3 with $q = p$, $r = N - 2p$ and $z_i = \delta_i$, so by that lemma its k-th running total — the largest sum of k of its entries — is $\sum_{j\le k} |\boldsymbol{\delta}|^{\downarrow}_j$. The right-hand vector is already decreasing, so its k-th running total is $\sum_{j\le k} \sigma_j(\mathbf{A} - \mathbf{B})$. Since $k \le p < N$, clause (M1) of Definition 16.8.1 applies at this k and gives

$$\sum_{j=1}^{k} |\boldsymbol{\delta}|^{\downarrow}_j \;\le\; \sum_{j=1}^{k} \sigma_j(\mathbf{A} - \mathbf{B}).$$

As $k \le p$ was arbitrary, this is Eq. 20.7.3, and Step 1 finishes the proof.

■

Remark. **Where the factor of two went.** Chapter 19 §10 proved the Frobenius case by taking a **norm** of the dilation, and paid for it: $\|\mathcal{H}(\mathbf{M})\|_F^2 = 2\|\mathbf{M}\|_F^2$, so a factor 2 appeared on each side and canceled. That cancellation is special to a norm which adds squares, and for a general unitarily invariant norm there is no such identity — indeed $|||\mathcal{H}(\mathbf{M})|||$ is a norm on a different matrix space, computed by a gauge on $\mathbb{R}^N$ rather than on $\mathbb{R}^p$. The proof above never takes a norm of a dilation. It uses the dilation only to obtain a **majorization of eigenvalue lists**, and then reads off the p running totals it needs. No factor of 2 arises, and none has to cancel.

Specializing the gauge recovers both statements that Chapter 19 §10 wanted inside one: $\Phi = \|\cdot\|_\infty$ gives $\max_i|\sigma_i(\mathbf{A}) - \sigma_i(\mathbf{B})| \le \|\mathbf{A}-\mathbf{B}\|_2$, which is Corollary 16.9.5, and $\Phi = \|\cdot\|_2$ gives Theorem 19.10.1. Chapter 19 §11's ledger entry — "extending the eigenvalue and singular value bounds to every unitarily invariant norm belongs to Chapter 20" — is now paid for the eigenvalue bounds by Theorem 20.7.2 and for the singular value bounds by Theorem 20.7.4. Chapter 19 §10's square-root and polar bounds (Theorem 19.10.2, Theorem 19.10.3, Theorem 19.10.4) are **not** extended here: they still hold only in the two norms Chapter 19 proved them in, the spectral and the Frobenius.

The pair of Example (A pair to keep in mind) illustrates the singular value form as well. There $\mathbf{A} = \left(\begin{smallmatrix} 2 & 2 \\ 2 & 2 \end{smallmatrix}\right)$ is positive semidefinite with eigenvalues $4, 0$, so $\sigma(\mathbf{A}) = (4, 0)$; $\mathbf{B}$ has eigenvalues ± 1, so $\sigma(\mathbf{B}) = (1, 1)$; and $\mathbf{A} - \mathbf{B}$ has eigenvalues $5, -1$, so $\sigma(\mathbf{A} - \mathbf{B}) = (5, 1)$. The vector of differences is $\sigma(\mathbf{A}) - \sigma(\mathbf{B}) = (3, -1)$, whose absolute values $(3, 1)$ have running totals $3 \le 5$ and $4 \le 6$: the weak majorization of Eq. 20.7.3, and with it the norm inequality in every unitarily invariant norm.

Warning. Both Theorem 20.7.2 and Theorem 20.7.4 compare **sorted** lists, and the matching they use is the sorted one. No claim is made for any other pairing, and Theorem 20.7.4 in particular is not a statement about eigenvalues: for non-Hermitian matrices the eigenvalues can be wildly unstable while the singular values are not, which is the whole content of Chapter 19 §10's remark that Mirsky's theorem needs no normality hypothesis at all.

20.7.5 Exercises

20.7.5.1 A. Check your understanding

Exercise A1.

(a) State the majorization Eq. 20.7.1, and say which chapter proves it.

(b) State Theorem 20.7.2, and say what $\mathrm{diag}(\boldsymbol{\lambda}(\mathbf{A}) - \boldsymbol{\lambda}(\mathbf{B}))$ means.

(c) Determine whether the following is true for Hermitian $\mathbf{A}, \mathbf{B}$, and justify your answer: $\sum_i|\lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})| \le \sum_i|\lambda_i(\mathbf{A} - \mathbf{B})|$.

(d) Determine whether the following is true, and justify your answer: Theorem 20.7.4 holds with the singular values of $\mathbf{A}$ and $\mathbf{B}$ listed in **increasing** order on the left.

(e) Where in the proof of Theorem 20.7.4 is it used that $\mathbf{A}$ and $\mathbf{B}$ have the same size?

Solution.

(a) For Hermitian $\mathbf{A}, \mathbf{B} \in M_n(F)$, $\boldsymbol{\lambda}(\mathbf{A}) - \boldsymbol{\lambda}(\mathbf{B}) \prec \boldsymbol{\lambda}(\mathbf{A} - \mathbf{B})$. It is proved in Chapter 16

§07, from Theorem 16.7.2 over all index sets together with the equality of traces.

(b) For every unitarily invariant norm, $\|\mathrm{diag}(\boldsymbol{\lambda}(\mathbf{A}) - \boldsymbol{\lambda}(\mathbf{B}))\| \le \|\mathbf{A} - \mathbf{B}\|$. The matrix $\mathrm{diag}(\mathbf{x})$ is the diagonal matrix in $M_n(F)$ whose i-th diagonal entry is x_i; here $x_i = \lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})$, the shift of the i-th eigenvalue, the lists being in decreasing order.

(c) True. Take $\phi(t) = |t|$ in Theorem 20.7.1; it is convex, being a norm on $\mathbb{R}$. Alternatively it is Theorem 20.7.2 for the trace norm, using Eq. 20.7.2.

(d) True, and for a cheap reason: reversing both lists changes the vector $\boldsymbol{\delta}$ only by reversing it, and the gauge of a unitarily invariant norm is permutation-invariant (Definition 20.3.1), so the left-hand side is unchanged. What would **not** be true is to sort one list increasingly and the other decreasingly; see the warning after Theorem 20.7.1.

(e) Twice. The two matrices must lie in the same space for $\mathbf{A} - \mathbf{B}$ to be defined and for one norm to apply to all three matrices; and in Step 2, m, n and p being the same for $\mathbf{A}$ and $\mathbf{B}$ is what puts the zeros of the two dilated spectra in the same positions, so that the difference of the two lists has the shape used in Step 4.

20.7.5.2 B. Practice

Exercise B1: Running the three consequences.

Let $\mathbf{A} = \mathrm{diag}(5, 1, 0)$ and let $\mathbf{B} = \mathbf{A} - \mathbf{E}$ with

$$\mathbf{E} = \begin{pmatrix} 0 & 0 & 2 \\ 0 & 0 & 0 \\ 2 & 0 & 0 \end{pmatrix}.$$

(a) Compute $\boldsymbol{\lambda}(\mathbf{B})$ and $\boldsymbol{\lambda}(\mathbf{E})$.

(b) Verify Eq. 20.7.1 for this pair.

(c) Verify Theorem 20.7.2 in the spectral, Frobenius and trace norms, and Corollary 20.7.3.

Solution.

(a) $\mathbf{E}$ acts as $\left(\begin{smallmatrix} 0 & 2 \\ 2 & 0 \end{smallmatrix}\right)$ on $\mathrm{span}(\mathbf{e}_1, \mathbf{e}_3)$ and as 0 on $\mathbf{e}_2$, so $\boldsymbol{\lambda}(\mathbf{E}) = (2, 0, -2)$. Next,

$$\mathbf{B} = \mathbf{A} - \mathbf{E} = \begin{pmatrix} 5 & 0 & -2 \\ 0 & 1 & 0 \\ -2 & 0 & 0 \end{pmatrix}.$$

On $\mathrm{span}(\mathbf{e}_1, \mathbf{e}_3)$ it is $\left(\begin{smallmatrix} 5 & -2 \\ -2 & 0 \end{smallmatrix}\right)$, with trace 5 and determinant -4, so its eigenvalues there are $(5 \pm \sqrt{41})/2$; together with the eigenvalue 1 from $\mathbf{e}_2$,

$$\boldsymbol{\lambda}(\mathbf{B}) = \left(\tfrac{5+\sqrt{41}}{2},\ 1,\ \tfrac{5-\sqrt{41}}{2}\right) \approx (5.702,\ 1,\ -0.702).$$

(b) The shifts are $\boldsymbol{\lambda}(\mathbf{A}) - \boldsymbol{\lambda}(\mathbf{B}) = (5 - \tfrac{5+\sqrt{41}}{2},\ 0,\ \tfrac{\sqrt{41}-5}{2}) = (\tfrac{5-\sqrt{41}}{2},\ 0,\ \tfrac{\sqrt{41}-5}{2}) \approx (-0.702,\ 0,\ 0.702)$. Sorted decreasingly this is $(0.702, 0, -0.702)$, with running totals $0.702,\ 0.702,\ 0$. The list $\boldsymbol{\lambda}(\mathbf{E}) = (2, 0, -2)$ has running totals $2, 2, 0$. Each of the first two is larger, and the totals agree at 0. So the majorization holds.

(c) Write $c = \frac{\sqrt{41}-5}{2} \approx 0.702$. The left-hand matrix is $\operatorname{diag}(-c, 0, c)$, whose singular values are $(c, c, 0)$; the right-hand matrix is $\mathbf{E}$, whose singular values are $(2, 2, 0)$. Spectral: $c \le 2$. Frobenius: $c\sqrt{2} \approx 0.993 \le 2\sqrt{2} \approx 2.828$. Trace: $2c \approx 1.403 \le 4$. Squaring the Frobenius comparison gives

$$2c^2 = \frac{(\sqrt{41}-5)^2}{2} = \frac{66-10\sqrt{41}}{2} = 33 - 5\sqrt{41} \approx 0.984$$

on the left and $\|\mathbf{E}\|_F^2 = 8$ on the right, which is Corollary 20.7.3.

Exercise B2: Singular values of a one-entry change.

Let $\mathbf{A} = \left(\begin{smallmatrix} 3 & 1 \\ 1 & 3 \end{smallmatrix}\right)$ and $\mathbf{B} = \left(\begin{smallmatrix} 3 & 1 \\ 0 & 3 \end{smallmatrix}\right)$. Compute both sides of Theorem 20.7.4 in the trace norm, and compare with what Corollary 16.9.5 gives on its own.

Solution. $\mathbf{A}$ is symmetric with eigenvalues 4 and 2, both positive, so $\sigma(\mathbf{A}) = (4, 2)$. For $\mathbf{B}$, $\mathbf{B}^\top\mathbf{B} = \left(\begin{smallmatrix} 9 & 3 \\ 3 & 10 \end{smallmatrix}\right)$, with trace 19 and determinant 81, so its eigenvalues are $\frac{19 \pm \sqrt{37}}{2}$; these are the squares of $\frac{\sqrt{37}\pm 1}{2}$, since $\left(\frac{\sqrt{37}\pm 1}{2}\right)^2 = \frac{38 \pm 2\sqrt{37}}{4}$. Hence

$$\sigma(\mathbf{B}) = \left(\tfrac{\sqrt{37}+1}{2},\ \tfrac{\sqrt{37}-1}{2}\right) \approx (3.541,\ 2.541).$$

The differences are $\sigma(\mathbf{A}) - \sigma(\mathbf{B}) = \left(\frac{7-\sqrt{37}}{2},\ \frac{5-\sqrt{37}}{2}\right) \approx (0.459,\ -0.541)$, so the left side in the trace norm is

$$\tfrac{7-\sqrt{37}}{2} + \tfrac{\sqrt{37}-5}{2} = 1.$$

On the right, $\mathbf{A} - \mathbf{B} = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$ has singular values $(1, 0)$, so $|||\mathbf{A} - \mathbf{B}||| = 1$ in the trace norm. The inequality holds with **equality** here.

Corollary 16.9.5 gives only $|\sigma_i(\mathbf{A}) - \sigma_i(\mathbf{B})| \le \|\mathbf{A} - \mathbf{B}\|_2 = 1$ for each i separately, hence at best 2 for the sum. Mirsky's theorem halves that, and here it is exact.

Exercise B3: A bound with no norm in sight.

Let $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$ be Hermitian with $\|\mathbf{A}-\mathbf{B}\|_2 \le \varepsilon$. Prove that $\sum_i |\lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})| \le n\varepsilon$, and give a pair for which this is an equality.

Solution. By Theorem 20.7.1 with $\phi(t) = |t|$,

$$\sum_i |\lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})| \le \sum_i |\lambda_i(\mathbf{A} - \mathbf{B})| \le n \max_i |\lambda_i(\mathbf{A} - \mathbf{B})| = n\|\mathbf{A} - \mathbf{B}\|_2 \le n\varepsilon,$$

the last equality by Lemma 16.3.5. For equality take $\mathbf{B} = \mathbf{A} - \varepsilon\mathbf{I}$: then $\lambda_i(\mathbf{B}) = \lambda_i(\mathbf{A}) - \varepsilon$ for every i, the left side is $n\varepsilon$, and $\|\mathbf{A} - \mathbf{B}\|_2 = \varepsilon$.

20.7.5.3 C. Going deeper

Exercise C1: The Schatten norms.

Recall the Schatten r-norm $|||\mathbf{M}|||_{S_r} = \left(\sum_i \sigma_i(\mathbf{M})^r\right)^{1/r}$ of Example (The Schatten norms), the unitarily invariant norm with gauge $\|\cdot\|_r$, and let $1 \le r < \infty$.

(a) Prove that for Hermitian $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$, $\sum_i |\lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})|^r \le \sum_i |\lambda_i(\mathbf{A} - \mathbf{B})|^r$, in two ways: from Theorem 20.7.1 and from Theorem 20.7.2.

(b) Deduce the same statement for singular values, with σ in place of λ and $\mathbf{A}, \mathbf{B}$ arbitrary of the same size.

Solution.

(a) *From Theorem 20.7.1.* First, $\phi(t) = |t|^r$ is convex on $\mathbb{R}$. For $r = 1$ this is $|t| = \max\{t, -t\}$, convex by Proposition 17.10.3. Let $r > 1$, let $a, b \in \mathbb{R}$ and let $0 < \theta < 1$ (the cases $\theta = 0, 1$ are equalities); write $\theta' = 1 - \theta$ and let $q = r/(r-1)$ be the exponent conjugate to r. Apply Theorem 17.11.4 in $\mathbb{R}^2$ to

$$\mathbf{x} = \big(\theta^{1/r}|a|,\ (\theta')^{1/r}|b|\big), \qquad \mathbf{y} = \big(\theta^{1/q},\ (\theta')^{1/q}\big).$$

Since $\frac{1}{r} + \frac{1}{q} = 1$, the rules for powers of Chapter 17 §11 give $\langle \mathbf{x}, \mathbf{y} \rangle = \theta|a| + \theta'|b|$ and $\|\mathbf{y}\|_q = (\theta + \theta')^{1/q} = 1$, so

$$\theta|a| + \theta'|b| \ \le\ \|\mathbf{x}\|_r = \big(\theta|a|^r + \theta'|b|^r\big)^{1/r}.$$

The function $u \mapsto u^r$ is increasing on $[0, \infty)$ (Chapter 17 §11), and $|\theta a + \theta' b| \le \theta|a| + \theta'|b|$ by Theorem 0.6.4, so raising the displayed inequality to the power r gives

$$|\theta a + \theta' b|^r \ \le\ \big(\theta|a| + \theta'|b|\big)^r \ \le\ \theta|a|^r + \theta'|b|^r,$$

which is Definition 17.10.1 for ϕ on $\mathbb{R}$. Now apply Theorem 20.7.1.
From Theorem 20.7.2. Take the Schatten r-norm, whose gauge is $\|\cdot\|_r$. The left-hand side of Theorem 20.7.2 is $\big(\sum_i |\lambda_i(\mathbf{A}) - \lambda_i(\mathbf{B})|^r\big)^{1/r}$ by Eq. 20.7.2, and the right-hand side is $\big(\sum_i |\lambda_i(\mathbf{A} - \mathbf{B})|^r\big)^{1/r}$, since $\mathbf{A} - \mathbf{B}$ is Hermitian. Raise to the power r.

(b) Apply Theorem 20.7.4 with the Schatten r-norm and raise to the power r, reading both sides through Theorem 20.4.3 as above.

Exercise C2: What the dilation costs.

Let $\mathbf{A}, \mathbf{B} \in M_{m \times n}(\mathbb{C})$ and let $\mathcal{H}(\cdot)$ be the Hermitian dilation of Proposition 16.9.3.

(a) Prove that $|||\mathcal{H}(\mathbf{A})|||$ and $|||\mathbf{A}|||$ cannot be compared in general, by computing both for the Frobenius norm and for the spectral norm with $\mathbf{A} = \mathbf{I}_2$.

(b) Explain, in one or two sentences, why the proof of Theorem 20.7.4 is nevertheless free of any such factor.

(c) Deduce Corollary 20.6.2 from Theorem 20.7.4, and say why Section 6 nevertheless proved it another way.

Hint: for (c), a matrix of rank at most k has $\sigma_i = 0$ for $i > k$.

Solution.

(a) For $\mathbf{A} = \mathbf{I}_2$, $\mathcal{H}(\mathbf{A}) \in M_4(\mathbb{C})$ has singular values $(1, 1, 1, 1)$, so $\|\mathcal{H}(\mathbf{A})\|_F = 2$ while $\|\mathbf{A}\|_F = \sqrt{2}$: the Frobenius norm grows by $\sqrt{2}$. The spectral norms, however, are both 1. So the ratio $|||\mathcal{H}(\mathbf{A})||| \,/\, |||\mathbf{A}|||$ depends on the norm, and there is no single

factor to divide out. (The two norms also live on different spaces, M_4 and M_2.)

(b) Because the dilation is used only to produce a majorization between **eigenvalue lists**, from which the required inequality between running totals of the p numbers $|\delta_i|$ and the p numbers $\sigma_j(\mathbf{A}-\mathbf{B})$ is read off directly. No norm is ever applied to a dilated matrix.

(c) Let $\operatorname{rank}\mathbf{B} \le k$, so $\sigma_i(\mathbf{B}) = 0$ for $i > k$ and hence $|\delta_i| = \sigma_i(\mathbf{A})$ for $i > k$, in the notation of the proof of Theorem 20.7.4. Let $\mathbf{z} \in \mathbb{R}^p$ have $z_i = 0$ for $i \le k$ and $z_i = \sigma_i(\mathbf{A})$ for $i > k$. Then $|z_i| \le |\delta_i|$ for every i, so Proposition 20.3.1 gives $\Phi(\mathbf{z}) \le \Phi(\boldsymbol{\delta})$; and $\Phi(\mathbf{z}) = \Phi(\sigma_{k+1}, \dots, \sigma_p, 0, \dots, 0)$ by the permutation invariance of Definition 20.3.1. Combining with Theorem 20.7.4,

$$\Phi(\sigma_{k+1}, \dots, \sigma_p, 0, \dots, 0) \le \Phi(\boldsymbol{\delta}) = \left\|\left|\operatorname{diag}_{m,n}(\boldsymbol{\delta})\right|\right\| \le \|\mathbf{A}-\mathbf{B}\|,$$

which is the bound of Corollary 20.6.2, attained at $\mathbf{A}_k$. Section 6 proved it earlier in the chapter, so it could not use this section; and its route gives more, namely $\sigma_i(\mathbf{A}-\mathbf{A}_k) \le \sigma_i(\mathbf{A}-\mathbf{B})$ index by index, which is the route Chapter 12 §10 predicted.

20.8 Operator Convex Functions

Chapter 16 §11 defined two notions side by side and then spent itself on one of them. Operator monotonicity got four families of examples, a warning and a classification to look forward to; operator convexity got one proposition — that $t \mapsto t^2$ is operator convex (Proposition 16.11.8) — and then the chapter moved on. This section repays the debt. It collects the examples that are within reach, and it proves the one structural theorem the notion has: an inequality of Jensen's type that survives being squeezed by a contraction. That theorem is what makes operator convexity useful rather than merely curious.

Throughout, $F = \mathbb{R}$ **or** $F = \mathbb{C}$, every matrix whose spectrum is named is Hermitian, and I denotes an **interval** of real numbers. The letter I is plain italic and is not the identity matrix $\mathbf{I}$. For $f\colon I \to \mathbb{R}$ and Hermitian $\mathbf{A}$ with $\operatorname{spec}(\mathbf{A}) \subseteq I$, the matrix $f(\mathbf{A})$ is the one built by the functional calculus of Chapter 11 §08 (Definition 11.8.2), and it is Hermitian because f is real-valued (Theorem 11.8.3 (c)).

20.8.1 What operator convexity asks

Recall the definition. A function $f\colon I \to \mathbb{R}$ is **operator convex on** I if, for **every** size $n \ge 1$, all Hermitian $\mathbf{A}, \mathbf{B} \in M_n(F)$ with spectra in I, and every $\theta \in [0,1]$,

$$f\big(\theta\mathbf{A} + (1-\theta)\mathbf{B}\big) \preceq \theta f(\mathbf{A}) + (1-\theta) f(\mathbf{B})$$

in the Loewner order (Definition 16.11.1 (b), Definition 12.5.1). It is **operator concave** when $-f$ is operator convex. Chapter 16 §11 checked that the left-hand side makes sense: the spectrum of a convex combination of two Hermitian matrices with spectra in I again lies in I.

Taking $n = 1$ turns every matrix into a number and the Loewner order into $\ge$, so an operator convex function is convex in the sense of Definition 17.10.1. As with monotonicity, the content lies in the sizes $n \ge 2$, and the clause "for every n" is what makes the class small.

Two facts from Chapter 16 §11 are the starting stock. Affine functions are operator convex and operator concave at once, with equality in the definition (Proposition 16.11.2), and $t \mapsto t^2$ is operator convex on $\mathbb{R}$, because

$$\theta\mathbf{A}^2 + (1-\theta)\mathbf{B}^2 - \big(\theta\mathbf{A} + (1-\theta)\mathbf{B}\big)^2 = \theta(1-\theta)(\mathbf{A}-\mathbf{B})^2$$

and the square of a Hermitian matrix is positive semidefinite (Proposition 16.11.8).

Before adding to the stock we record three bookkeeping identities. Each says that a familiar operation on matrices passes through the functional calculus untouched, and each is used below without further comment.

Lemma 20.8.1 — Three Ways to Move the Functional Calculus

Let $I \subseteq \mathbb{R}$ be an interval and $f\colon I \to \mathbb{R}$.

(a) **(Shift.)** Let $s \in \mathbb{R}$, let $g(t) = f(t+s)$ on $I - s$, and let $\mathbf{A}$ be Hermitian with $\operatorname{spec}(\mathbf{A}) \subseteq I - s$. Then $g(\mathbf{A}) = f(\mathbf{A} + s\mathbf{I})$.

(b) **(Unitary conjugation.)** Let $\mathbf{A}$ be Hermitian with $\operatorname{spec}(\mathbf{A}) \subseteq I$ and let $\mathbf{U}$ be unitary of the same size. Then $\operatorname{spec}(\mathbf{U}^*\mathbf{A}\mathbf{U}) = \operatorname{spec}(\mathbf{A})$ and

$$f(\mathbf{U}^*\mathbf{A}\mathbf{U}) = \mathbf{U}^* f(\mathbf{A})\mathbf{U}.$$

(c) **(Direct sums.)** Let $\mathbf{A}, \mathbf{B}$ be Hermitian with spectra in I. Then $f(\mathbf{A} \oplus \mathbf{B}) = f(\mathbf{A}) \oplus f(\mathbf{B})$.

Proof. Write the spectral resolution $\mathbf{A} = \sum_j \mu_j \mathbf{P}_j$ with distinct μ_j (Definition 11.8.1, Theorem 11.8.1).

(a) The numbers $\mu_j + s$ are distinct, and $\mathbf{A} + s\mathbf{I} = \sum_j (\mu_j + s)\mathbf{P}_j$ by Theorem 11.8.1 (c) and (d). The $\mathbf{P}_j$ are non-zero self-adjoint idempotents, pairwise annihilating and summing to $\mathbf{I}$ (Theorem 11.8.1 (b), (c)), so this is the spectral resolution of $\mathbf{A} + s\mathbf{I}$ by Theorem 11.8.2. Hence $f(\mathbf{A} + s\mathbf{I}) = \sum_j f(\mu_j + s)\mathbf{P}_j = \sum_j g(\mu_j)\mathbf{P}_j = g(\mathbf{A})$, using Definition 11.8.2 twice.

(b) Put $\mathbf{Q}_j = \mathbf{U}^*\mathbf{P}_j\mathbf{U}$. Each $\mathbf{Q}_j$ is self-adjoint, $\mathbf{Q}_j^2 = \mathbf{U}^*\mathbf{P}_j\mathbf{U}\mathbf{U}^*\mathbf{P}_j\mathbf{U} = \mathbf{Q}_j$, and $\mathbf{Q}_i\mathbf{Q}_j = \mathbf{0}$ for $i \neq j$, all because $\mathbf{U}\mathbf{U}^* = \mathbf{I}$; moreover $\sum_j \mathbf{Q}_j = \mathbf{U}^*\mathbf{I}\mathbf{U} = \mathbf{I}$ and $\mathbf{Q}_j \neq \mathbf{0}$ since $\mathbf{U}$ is invertible. Also $\mathbf{U}^*\mathbf{A}\mathbf{U} = \sum_j \mu_j \mathbf{Q}_j$. So this is the spectral resolution of $\mathbf{U}^*\mathbf{A}\mathbf{U}$ by Theorem 11.8.2, its distinct eigenvalues are the μ_j, and

$$f(\mathbf{U}^*\mathbf{A}\mathbf{U}) = \sum_j f(\mu_j)\mathbf{Q}_j = \mathbf{U}^*\Big(\sum_j f(\mu_j)\mathbf{P}_j\Big)\mathbf{U} = \mathbf{U}^* f(\mathbf{A})\mathbf{U}.$$

(c) Let $\nu_1, \dots, \nu_r$ be the distinct elements of $\operatorname{spec}(\mathbf{A}) \cup \operatorname{spec}(\mathbf{B})$. For each ν, let $\mathbf{P}_\nu^{\mathbf{A}}$ be the orthogonal projection onto $E_\nu(\mathbf{A})$, understood as $\mathbf{0}$ when $\nu \notin \operatorname{spec}(\mathbf{A})$, and likewise $\mathbf{P}_\nu^{\mathbf{B}}$. A vector $(\mathbf{x}, \mathbf{y})$ satisfies $(\mathbf{A} \oplus \mathbf{B})(\mathbf{x}, \mathbf{y}) = \nu(\mathbf{x}, \mathbf{y})$ exactly when $\mathbf{A}\mathbf{x} = \nu\mathbf{x}$ and $\mathbf{B}\mathbf{y} = \nu\mathbf{y}$, so $E_\nu(\mathbf{A} \oplus \mathbf{B}) = E_\nu(\mathbf{A}) \oplus E_\nu(\mathbf{B})$, whose orthogonal projection is $\mathbf{P}_\nu^{\mathbf{A}} \oplus \mathbf{P}_\nu^{\mathbf{B}}$. Hence $\operatorname{spec}(\mathbf{A} \oplus \mathbf{B}) = \{\nu_1, \dots, \nu_r\} \subseteq I$ and, by Definition 11.8.2,

$$f(\mathbf{A} \oplus \mathbf{B}) = \sum_\nu f(\nu)\big(\mathbf{P}_\nu^{\mathbf{A}} \oplus \mathbf{P}_\nu^{\mathbf{B}}\big) = f(\mathbf{A}) \oplus f(\mathbf{B}).$$

■

20.8.2 The examples we can prove

Operator convex functions form a cone, exactly as the operator monotone ones do, and for the same reason.

Proposition 20.8.2 — Combining Operator Convex Functions

Let f and g be operator convex on I.

(a) For all $c \geq 0$ and $\alpha, \beta \in \mathbb{R}$, the functions $f + g$ and $\alpha + \beta t + cf(t)$ are operator convex on I.

(b) For every $s \in \mathbb{R}$, the translate $t \mapsto f(t + s)$ is operator convex on $I - s$.

Proof.

(a) Fix Hermitian $\mathbf{A}, \mathbf{B}$ of the same size with spectra in I, fix $\theta \in [0, 1]$ and put $\mathbf{C} = \theta\mathbf{A} + (1 - \theta)\mathbf{B}$. By Theorem 11.8.3 (b), the defect

$$D_h := \theta h(\mathbf{A}) + (1 - \theta)h(\mathbf{B}) - h(\mathbf{C})$$

satisfies $D_{f+g} = D_f + D_g$ and $D_{cf} = c\, D_f$. Both D_f and D_g are $\succeq 0$ by hypothesis, so for every $\mathbf{x}$ the quadratic forms add and scale to something ≥ 0, giving $D_{f+g} \succeq 0$ and $D_{cf} \succeq 0$. Adding an affine function changes nothing, since $D_h = \mathbf{0}$ for affine h by Proposition 16.11.2.

(b) Let $g(t) = f(t + s)$ and let $\mathbf{A}, \mathbf{B}$ be Hermitian with spectra in $I - s$. Then $\mathbf{A} + s\mathbf{I}$ and $\mathbf{B} + s\mathbf{I}$ have spectra in I, and $\theta(\mathbf{A} + s\mathbf{I}) + (1 - \theta)(\mathbf{B} + s\mathbf{I}) = \mathbf{C} + s\mathbf{I}$. By Lemma 20.8.1 (a) applied three times,

$$g(\mathbf{C}) = f(\mathbf{C} + s\mathbf{I}) \preceq \theta f(\mathbf{A} + s\mathbf{I}) + (1 - \theta) f(\mathbf{B} + s\mathbf{I}) = \theta g(\mathbf{A}) + (1 - \theta) g(\mathbf{B}).$$

■

The new example is the reciprocal. Chapter 16 §11 left it as an exercise; part (d) of the theorem below rests on it, so it is proved here. The proof is the one the exercise's hint pointed at, and the whole content is that a positive definite matrix and its inverse sit in a single positive semidefinite block matrix.

Theorem 20.8.3 — Four Operator Convex Functions (a) Every affine function $t \mapsto \alpha + \beta t$ is operator convex and operator concave on $\mathbb{R}$.

(b) $t \mapsto t^2$ is operator convex on $\mathbb{R}$, hence on every interval.

(c) $t \mapsto 1/t$ is operator convex on $(0, \infty)$; equivalently, $t \mapsto -1/t$ is operator concave there.

(d) For every $c > 0$, the function $t \mapsto 1/(t + c)$ is operator convex on $(0, \infty)$, and $t \mapsto t/(t + c)$ is operator **concave** there.

Idea. Only (c) is new. For numbers, $1/t$ is convex because $1/t$ is the smallest u with $tu \geq 1$, and "$tu \geq 1$" is a condition that survives averaging. The matrix version of "$tu \geq 1$" is that the block matrix $\left(\begin{smallmatrix} \mathbf{A} & \mathbf{I} \\ \mathbf{I} & \mathbf{U} \end{smallmatrix}\right)$ is positive semidefinite, and Chapter 12 §06

reads that off a Schur complement. Averaging two such blocks averages the corners, and reading the Schur complement backwards turns the average back into an inequality between matrices.

Proof.

(a) is Proposition 16.11.2 and (b) is Proposition 16.11.8. Restricting to a smaller interval only shrinks the supply of matrices, so both persist on every interval.

(b) **Claim.** For every $\mathbf{G} \succ 0$ in $M_n(F)$, the Hermitian block matrix

$$\mathbf{M}_{\mathbf{G}} = \begin{pmatrix} \mathbf{G} & \mathbf{I}_n \\ \mathbf{I}_n & \mathbf{G}^{-1} \end{pmatrix}$$

is positive semidefinite.

Proof. The inverse of a Hermitian invertible matrix is Hermitian, since $(\mathbf{G}^{-1})^* = (\mathbf{G}^*)^{-1} = \mathbf{G}^{-1}$, so $\mathbf{M}_{\mathbf{G}}$ is Hermitian. Its corner $\mathbf{G}$ is $\succ 0$, and its Schur complement is $\mathbf{M}_{\mathbf{G}}/\mathbf{G} = \mathbf{G}^{-1} - \mathbf{I}_n\mathbf{G}^{-1}\mathbf{I}_n = \mathbf{0} \succeq 0$. By Theorem 12.6.1 (b), $\mathbf{M}_{\mathbf{G}} \succeq 0$. ∎

Now let $\mathbf{A}, \mathbf{B} \in M_n(F)$ be Hermitian with spectra in $(0, \infty)$, so $\mathbf{A} \succ 0$ and $\mathbf{B} \succ 0$ by Theorem 12.1.5 (b), and let $\theta \in [0, 1]$. Put $\mathbf{C} = \theta\mathbf{A} + (1-\theta)\mathbf{B}$. For $\mathbf{x} \neq \mathbf{0}$,

$$\langle \mathbf{C}\mathbf{x}, \mathbf{x} \rangle = \theta\langle \mathbf{A}\mathbf{x}, \mathbf{x} \rangle + (1-\theta)\langle \mathbf{B}\mathbf{x}, \mathbf{x} \rangle > 0,$$

since both terms are ≥ 0 and at least one coefficient is positive; hence $\mathbf{C} \succ 0$. By the Claim, $\mathbf{M}_{\mathbf{A}} \succeq 0$ and $\mathbf{M}_{\mathbf{B}} \succeq 0$, so their convex combination

$$\theta\mathbf{M}_{\mathbf{A}} + (1-\theta)\mathbf{M}_{\mathbf{B}} = \begin{pmatrix} \mathbf{C} & \mathbf{I}_n \\ \mathbf{I}_n & \theta\mathbf{A}^{-1} + (1-\theta)\mathbf{B}^{-1} \end{pmatrix}$$

has non-negative quadratic form at every vector and is therefore $\succeq 0$. Its corner $\mathbf{C}$ is $\succ 0$, so Theorem 12.6.1 (b) applies in the other direction and gives

$$\theta\mathbf{A}^{-1} + (1-\theta)\mathbf{B}^{-1} - \mathbf{C}^{-1} \;\succeq\; 0.$$

Since $t \mapsto 1/t$ sends a positive definite matrix to its inverse (Definition 11.8.2, as recalled in Chapter 16 §11), this is exactly the inequality required of $f(t) = 1/t$. The size n was arbitrary.

(d) By (c) and Proposition 20.8.2 (b), $t \mapsto 1/(t+c)$ is operator convex on $(0, \infty) - c = (-c, \infty)$, hence on the smaller interval $(0, \infty)$. Finally $t/(t+c) = 1 - c \cdot \frac{1}{t+c}$, which is an affine function minus a non-negative multiple of an operator convex function, so it is operator concave by Proposition 20.8.2 (a) applied to $-f$.

∎

Remark. Compare the list with Chapter 16 §11's list of operator monotone functions. The two overlap only in the affine ones: t^2 is operator convex and not operator monotone, $-1/t$ is operator monotone and not even convex, and $t/(t+c)$ is both operator monotone (Corollary 16.11.5) and operator concave. Two further examples, $-\log t$ and $t \log t$, are operator convex on $(0, \infty)$; both proofs need an integral representation that §10 of this

chapter supplies, so they are postponed to there.

20.8.3 Convex is not operator convex

The gap between convexity and operator convexity is as wide as the gap between increasing and operator monotone, and a single cube exposes it.

Example. (The Cube Is Convex and Not Operator Convex)

Let

$$\mathbf{A} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}.$$

Show that $\mathbf{A} \succeq 0$ and $\mathbf{B} \succ 0$, and that with $\theta = \frac{1}{2}$ the inequality required of $f(t) = t^3$ on $[0, \infty)$ fails.

Solution. $\mathbf{A}$ is diagonal with non-negative entries, so $\mathbf{A} \succeq 0$ with spectrum $\{0, 1\}$. $\mathbf{B}$ is real symmetric with leading principal minors 2 and $2 - 1 = 1$, both positive, so $\mathbf{B} \succ 0$ by Sylvester's criterion (Theorem 12.1.5 (d)). Both spectra lie in $[0, \infty)$, and so does that of $\frac{1}{2}(\mathbf{A} + \mathbf{B})$, a convex combination of two positive semidefinite matrices.

Now compute. $\mathbf{A}^3 = \mathbf{A}$. From $\mathbf{B}^2 = \left(\begin{smallmatrix} 5 & 3 \\ 3 & 2 \end{smallmatrix}\right)$ we get $\mathbf{B}^3 = \left(\begin{smallmatrix} 13 & 8 \\ 8 & 5 \end{smallmatrix}\right)$. Also $\mathbf{A} + \mathbf{B} = \left(\begin{smallmatrix} 3 & 1 \\ 1 & 1 \end{smallmatrix}\right)$, whose square is $\left(\begin{smallmatrix} 10 & 4 \\ 4 & 2 \end{smallmatrix}\right)$ and whose cube is $\left(\begin{smallmatrix} 34 & 14 \\ 14 & 6 \end{smallmatrix}\right)$. Hence, clearing the denominator by a factor 8,

$$8\Big(\tfrac{1}{2}(\mathbf{A}^3 + \mathbf{B}^3) - \big(\tfrac{1}{2}(\mathbf{A} + \mathbf{B})\big)^3\Big) = 4(\mathbf{A}^3 + \mathbf{B}^3) - (\mathbf{A} + \mathbf{B})^3 = \begin{pmatrix} 22 & 18 \\ 18 & 14 \end{pmatrix}.$$

Its determinant is $22 \cdot 14 - 18^2 = 308 - 324 = -16 < 0$, so it is not positive semidefinite (Theorem 12.1.4 (e)). A witness needs no eigenvalues: with $\mathbf{x} = (2, -3)$,

$$\mathbf{x}^\top \begin{pmatrix} 22 & 18 \\ 18 & 14 \end{pmatrix} \mathbf{x} = 4 \cdot 22 - 12 \cdot 18 + 9 \cdot 14 = 88 - 216 + 126 = -2 < 0.$$

By Theorem 11.8.3 (a), $t \mapsto t^3$ sends a Hermitian matrix to its cube, so t^3 is not operator convex on $[0, \infty)$. It is nevertheless convex there in the ordinary sense, since its second derivative $6t$ is ≥ 0 (Theorem 17.10.6).

Warning. **Convexity of f is not enough, already at size 2.** Every t^p with $p \geq 1$ is convex on $[0, \infty)$, and the exponents 3 and 4 already fail to be operator convex. The trace does not notice the difference: §02's Theorem 20.2.8 makes $\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A})$ convex for **every** convex f, and in Example (The Cube Is Convex and Not Operator Convex) the trace of the displayed matrix is $22 + 14 = 36 > 0$, exactly as that theorem predicts, while the matrix itself is indefinite. A convex function controls the sum of the eigenvalues; an operator convex function controls the matrix.

Quick check. Is $t \mapsto t^4$ operator convex on $[0, \infty)$, because $t^4 = (t^2)^2$ is a composite of two operator convex functions?

Solution. No. Proposition 20.8.2 covers sums and non-negative multiples, never composites, and there is no reason it should: operator convexity of g constrains g on convex

combinations of matrices, while $(g \circ f)(\mathbf{A}) = g(f(\mathbf{A}))$ asks about g at the matrix $f(\mathbf{A})$, which is a different question. The same pair as in Example (The Cube Is Convex and Not Operator Convex) settles it. From $\mathbf{A}^4 = \mathbf{A}$, $\mathbf{B}^4 = \left(\begin{smallmatrix} 34 & 21 \\ 21 & 13 \end{smallmatrix}\right)$ and $(\mathbf{A}+\mathbf{B})^4 = \left(\begin{smallmatrix} 116 & 48 \\ 48 & 20 \end{smallmatrix}\right)$,

$$4\Big(\tfrac{1}{2}(\mathbf{A}^4 + \mathbf{B}^4) - \big(\tfrac{1}{2}(\mathbf{A}+\mathbf{B})\big)^4\Big) = \begin{pmatrix} 41 & 30 \\ 30 & 21 \end{pmatrix},$$

whose determinant is $861 - 900 = -39 < 0$. A witness is $\mathbf{x} = (3, -4)$, giving $9 \cdot 41 - 24 \cdot 30 + 16 \cdot 21 = -15 < 0$.

20.8.4 Contractions and their dilations

The theorem this section is heading for compares $f(\mathbf{V}^*\mathbf{A}\mathbf{V})$ with $\mathbf{V}^* f(\mathbf{A})\mathbf{V}$. The matrices $\mathbf{V}$ for which this can possibly work are the ones that do not stretch: otherwise $\mathbf{V}^*\mathbf{A}\mathbf{V}$ can leave the interval where f lives.

A contraction is a matrix that never lengthens a vector.

Definition 20.8.1 — Contraction

Let $\mathbf{V} \in M_{n\times m}(F)$. Then $\mathbf{V}$ is a **contraction** if $\mathbf{V}^*\mathbf{V} \preceq \mathbf{I}_m$, that is, if $\|\mathbf{V}\mathbf{x}\| \le \|\mathbf{x}\|$ for every $\mathbf{x} \in F^m$. It is an **isometry** if $\mathbf{V}^*\mathbf{V} = \mathbf{I}_m$.

The word is overloaded: Chapter 14 §04 uses **contraction** for the pairing $V^* \otimes V \to F$ (Definition 14.4.1), which is a different object entirely, and the two never appear together. The two phrasings above agree because $\langle (\mathbf{I}_m - \mathbf{V}^*\mathbf{V})\mathbf{x}, \mathbf{x}\rangle = \|\mathbf{x}\|^2 - \|\mathbf{V}\mathbf{x}\|^2$. Examples: every unitary matrix; every orthogonal projection $\mathbf{P}$, since $\mathbf{P}^*\mathbf{P} = \mathbf{P}^2 = \mathbf{P} \preceq \mathbf{I}$ (Definition 12.5.1); the matrix $\tfrac{1}{2}\mathbf{I}$; and any matrix whose columns are an orthonormal list, which is an isometry. A non-example by minimal change: $2\mathbf{I}$ fails, since $\mathbf{I} - (2\mathbf{I})^*(2\mathbf{I}) = -3\mathbf{I}$ is not positive semidefinite.

The key structural fact is that a contraction is always the corner of a unitary matrix of twice the size. This is the **dilation**, and it is how a statement about contractions gets converted into a statement about unitary conjugation, which the functional calculus understands.

Lemma 20.8.4 — Unitary Dilation of a Contraction

Let $\mathbf{V} \in M_{n\times m}(F)$ be a contraction, and set

$$\mathbf{D}_1 = (\mathbf{I}_m - \mathbf{V}^*\mathbf{V})^{1/2}, \qquad \mathbf{D}_2 = (\mathbf{I}_n - \mathbf{V}\mathbf{V}^*)^{1/2}.$$

Then $\mathbf{I}_m - \mathbf{V}^*\mathbf{V} \succeq 0$ and $\mathbf{I}_n - \mathbf{V}\mathbf{V}^* \succeq 0$, so both square roots exist, and the $(n+m)\times(n+m)$ matrix

$$\mathbf{U} = \begin{pmatrix} \mathbf{V} & \mathbf{D}_2 \\ \mathbf{D}_1 & -\mathbf{V}^* \end{pmatrix}$$

is unitary.

Idea. Only one of the four block identities needs an idea: $\mathbf{V}^*\mathbf{D}_2 = \mathbf{D}_1\mathbf{V}^*$, which says that $\mathbf{V}^*$ intertwines the two square roots. It holds for $\mathbf{V}^*(\mathbf{I} - \mathbf{V}\mathbf{V}^*) = (\mathbf{I} - \mathbf{V}^*\mathbf{V})\mathbf{V}^*$ by one line of algebra, hence for every polynomial in the two matrices, and the positive

square root **is** a polynomial (Theorem 12.2.1 (a)) — provided one polynomial can be chosen to serve both matrices at once, which Lagrange interpolation allows.

Proof. Write $\mathbf{M} = \mathbf{I}_m - \mathbf{V}^*\mathbf{V}$ and $\mathbf{N} = \mathbf{I}_n - \mathbf{V}\mathbf{V}^*$. By hypothesis $\mathbf{M} \succeq 0$, which says $\|\mathbf{V}\mathbf{x}\| \le \|\mathbf{x}\|$ for every $\mathbf{x} \in F^m$. For $\mathbf{N}$, fix $\mathbf{y} \in F^n$ and put $\mathbf{z} = \mathbf{V}^*\mathbf{y}$. Then, by Cauchy–Schwarz (Theorem 10.1.5) and the contraction property applied to $\mathbf{z}$,

$$\|\mathbf{z}\|^2 = \langle \mathbf{V}\mathbf{z}, \mathbf{y}\rangle \;\le\; \|\mathbf{V}\mathbf{z}\|\,\|\mathbf{y}\| \;\le\; \|\mathbf{z}\|\,\|\mathbf{y}\|,$$

the first equality because $\langle \mathbf{V}\mathbf{z}, \mathbf{y}\rangle = \mathbf{y}^*\mathbf{V}\mathbf{V}^*\mathbf{y} = \|\mathbf{V}^*\mathbf{y}\|^2$. If $\mathbf{z} \neq \mathbf{0}$ we may divide by $\|\mathbf{z}\| > 0$ to get $\|\mathbf{V}^*\mathbf{y}\| \le \|\mathbf{y}\|$, and if $\mathbf{z} = \mathbf{0}$ that inequality is immediate. Hence $\langle \mathbf{N}\mathbf{y}, \mathbf{y}\rangle = \|\mathbf{y}\|^2 - \|\mathbf{V}^*\mathbf{y}\|^2 \ge 0$ for every $\mathbf{y}$, so $\mathbf{N} \succeq 0$. Both square roots now exist and are Hermitian, by Theorem 12.2.1.

Claim. $\mathbf{V}^*\mathbf{N}^{1/2} = \mathbf{M}^{1/2}\mathbf{V}^*$.

Proof. First, $\mathbf{V}^*\mathbf{N} = \mathbf{V}^* - \mathbf{V}^*\mathbf{V}\mathbf{V}^* = \mathbf{M}\mathbf{V}^*$. Hence $\mathbf{V}^*\mathbf{N}^k = \mathbf{M}^k\mathbf{V}^*$ for every integer $k \ge 0$, by induction: the case $k = 0$ is trivial, and $\mathbf{V}^*\mathbf{N}^{k+1} = (\mathbf{V}^*\mathbf{N})\mathbf{N}^k = \mathbf{M}(\mathbf{V}^*\mathbf{N}^k) = \mathbf{M}^{k+1}\mathbf{V}^*$. Therefore $\mathbf{V}^* q(\mathbf{N}) = q(\mathbf{M})\mathbf{V}^*$ for every polynomial q with real coefficients.

The set $\operatorname{spec}(\mathbf{M}) \cup \operatorname{spec}(\mathbf{N})$ is finite and contained in $[0, \infty)$, so by Lagrange interpolation (Theorem 5.6.1) there is a real polynomial q with $q(\nu) = \sqrt{\nu}$ for every ν in it. By Theorem 11.8.3 (a) and Definition 11.8.2, $q(\mathbf{M}) = \sum_j q(\mu_j)\mathbf{P}_j = \sum_j \sqrt{\mu_j}\mathbf{P}_j = \mathbf{M}^{1/2}$, and likewise $q(\mathbf{N}) = \mathbf{N}^{1/2}$. Substituting q into the displayed identity proves the claim.

■

Taking adjoints in the claim, and using that $\mathbf{M}^{1/2}$ and $\mathbf{N}^{1/2}$ are Hermitian, gives $\mathbf{N}^{1/2}\mathbf{V} = \mathbf{V}\mathbf{M}^{1/2}$. Now compute, in blocks (Theorem 7.1.1),

$$\begin{aligned}\mathbf{U}^*\mathbf{U} &= \begin{pmatrix} \mathbf{V}^* & \mathbf{D}_1 \\ \mathbf{D}_2 & -\mathbf{V} \end{pmatrix}\begin{pmatrix} \mathbf{V} & \mathbf{D}_2 \\ \mathbf{D}_1 & -\mathbf{V}^* \end{pmatrix} \\ &= \begin{pmatrix} \mathbf{V}^*\mathbf{V} + \mathbf{D}_1^2 & \mathbf{V}^*\mathbf{D}_2 - \mathbf{D}_1\mathbf{V}^* \\ \mathbf{D}_2\mathbf{V} - \mathbf{V}\mathbf{D}_1 & \mathbf{D}_2^2 + \mathbf{V}\mathbf{V}^* \end{pmatrix}.\end{aligned}$$

The top-left block is $\mathbf{V}^*\mathbf{V} + \mathbf{M} = \mathbf{I}_m$ and the bottom-right is $\mathbf{N} + \mathbf{V}\mathbf{V}^* = \mathbf{I}_n$, both by the definition of $\mathbf{M}$ and $\mathbf{N}$. The top-right block is $\mathbf{0}$ by the Claim, and the bottom-left is $\mathbf{0}$ by its adjoint form. So $\mathbf{U}^*\mathbf{U} = \mathbf{I}_{m+n}$, and since $\mathbf{U}$ is square this makes $\mathbf{U}$ unitary (Theorem 2.4.4).

■

Quick check. Take $m = n = 1$ and $\mathbf{V} = (c)$ with c real, $|c| \le 1$. What is the dilation?

Solution. $\mathbf{D}_1 = \mathbf{D}_2 = (\sqrt{1-c^2})$, so $\mathbf{U} = \begin{pmatrix} c & \sqrt{1-c^2} \\ \sqrt{1-c^2} & -c \end{pmatrix}$. Writing $c = \cos\varphi$ with $\varphi \in [0, \pi]$, so that $\sin\varphi \ge 0$ and $\sqrt{1-c^2} = \sin\varphi$, this is the reflection matrix $\begin{pmatrix} \cos\varphi & \sin\varphi \\ \sin\varphi & -\cos\varphi \end{pmatrix}$, which is orthogonal with determinant -1. So the lemma is the statement that every number in $[-1, 1]$ is the corner of a 2×2 reflection — the sentence "$\cos^2\varphi + \sin^2\varphi = 1$", read as a matrix identity.

20.8.5 Jensen's inequality for operators

Here is the theorem. In words: **squeezing first and then applying f is at most applying f first and then squeezing**, provided f is operator convex and does not reward the squeezing at the origin.

Theorem 20.8.5 — Hansen–Pedersen–Jensen Inequality

Let $I \subseteq \mathbb{R}$ be an interval with $0 \in I$, let $f\colon I \to \mathbb{R}$ be operator convex on I, let $\mathbf{A} \in M_n(F)$ be Hermitian with $\operatorname{spec}(\mathbf{A}) \subseteq I$, and let $\mathbf{V} \in M_{n\times m}(F)$ be a contraction. Then $\operatorname{spec}(\mathbf{V}^*\mathbf{A}\mathbf{V}) \subseteq I$, and

$$f(\mathbf{V}^*\mathbf{A}\mathbf{V}) \preceq \mathbf{V}^* f(\mathbf{A})\mathbf{V} + f(0)\big(\mathbf{I}_m - \mathbf{V}^*\mathbf{V}\big).$$

In particular:

(a) if $f(0) \le 0$, then $f(\mathbf{V}^*\mathbf{A}\mathbf{V}) \preceq \mathbf{V}^* f(\mathbf{A})\mathbf{V}$;
(b) if $\mathbf{V}$ is an isometry, then $f(\mathbf{V}^*\mathbf{A}\mathbf{V}) \preceq \mathbf{V}^* f(\mathbf{A})\mathbf{V}$, with no condition on $f(0)$.

Idea. Dilate. Once $\mathbf{V}$ sits in the corner of a unitary $\mathbf{U}$, the matrix $\mathbf{V}^*\mathbf{A}\mathbf{V}$ sits in the corner of $\mathbf{U}^*(\mathbf{A}\oplus\mathbf{0})\mathbf{U}$, which is a unitary conjugate of $\mathbf{A}\oplus\mathbf{0}$ and therefore has the same spectrum. Conjugating a second time by the sign matrix $\mathbf{W} = \mathbf{I}_m \oplus (-\mathbf{I}_n)$ flips the off-diagonal blocks, so **averaging the two conjugates deletes them**: the average is block diagonal, with $\mathbf{V}^*\mathbf{A}\mathbf{V}$ in the corner. Operator convexity applied to that average, and then reading off the top-left block, is the whole proof. The term $f(0)(\mathbf{I} - \mathbf{V}^*\mathbf{V})$ is the residue of the zero block we padded with.

Proof. **The spectrum.** Let $\mathbf{x} \in F^m$ be a unit eigenvector of the Hermitian matrix $\mathbf{V}^*\mathbf{A}\mathbf{V}$, with eigenvalue μ. If $\mathbf{V}\mathbf{x} = \mathbf{0}$, then $\mu = \langle \mathbf{V}^*\mathbf{A}\mathbf{V}\mathbf{x}, \mathbf{x}\rangle = 0 \in I$. Otherwise put $\mathbf{y} = \mathbf{V}\mathbf{x}/\|\mathbf{V}\mathbf{x}\|$ and $\tau = \|\mathbf{V}\mathbf{x}\|^2$, so $0 < \tau \le 1$ because $\mathbf{V}$ is a contraction, and

$$\mu = \langle \mathbf{A}\mathbf{V}\mathbf{x}, \mathbf{V}\mathbf{x}\rangle = \tau\langle \mathbf{A}\mathbf{y}, \mathbf{y}\rangle.$$

By Lemma 12.5.2, $\langle \mathbf{A}\mathbf{y}, \mathbf{y}\rangle$ lies between $\lambda_n(\mathbf{A})$ and $\lambda_1(\mathbf{A})$, hence in I, since I is an interval containing the spectrum. Then $\mu = \tau\langle \mathbf{A}\mathbf{y}, \mathbf{y}\rangle + (1-\tau)\cdot 0$ is a convex combination of two points of I, so $\mu \in I$. The same argument applies to $\mathbf{D}_2 = (\mathbf{I}_n - \mathbf{V}\mathbf{V}^*)^{1/2}$: it is Hermitian with $\mathbf{D}_2^*\mathbf{D}_2 = \mathbf{I}_n - \mathbf{V}\mathbf{V}^* \preceq \mathbf{I}_n$, because $\mathbf{V}\mathbf{V}^* \succeq 0$, so it is a contraction. Hence $\operatorname{spec}(\mathbf{D}_2\mathbf{A}\mathbf{D}_2) \subseteq I$.

The two conjugates. Let $\mathbf{U}$ be the dilation of Lemma 20.8.4 and put

$$\mathbf{M} = \mathbf{A} \oplus \mathbf{0}_m, \qquad \mathbf{W} = \mathbf{I}_m \oplus (-\mathbf{I}_n),$$

so that $\mathbf{W}$ is unitary and Hermitian, and $\operatorname{spec}(\mathbf{M}) = \operatorname{spec}(\mathbf{A}) \cup \{0\} \subseteq I$. Multiplying out in blocks,

$$\mathbf{U}^*\mathbf{M}\mathbf{U} = \begin{pmatrix} \mathbf{V}^*\mathbf{A}\mathbf{V} & \mathbf{V}^*\mathbf{A}\mathbf{D}_2 \\ \mathbf{D}_2\mathbf{A}\mathbf{V} & \mathbf{D}_2\mathbf{A}\mathbf{D}_2 \end{pmatrix},$$

and conjugating by $\mathbf{W}$ negates the two off-diagonal blocks. Hence, with $\mathbf{X} = \mathbf{U}^*\mathbf{M}\mathbf{U}$ and $\mathbf{Y} = (\mathbf{U}\mathbf{W})^*\mathbf{M}(\mathbf{U}\mathbf{W}) = \mathbf{W}^*\mathbf{X}\mathbf{W}$,

$$\tfrac{1}{2}(\mathbf{X} + \mathbf{Y}) = \big(\mathbf{V}^*\mathbf{A}\mathbf{V}\big) \oplus \big(\mathbf{D}_2\mathbf{A}\mathbf{D}_2\big). \tag{$*$}$$

Both $\mathbf{X}$ and $\mathbf{Y}$ are unitary conjugates of $\mathbf{M}$, so both are Hermitian with spectrum $\operatorname{spec}(\mathbf{M}) \subseteq I$ by Lemma 20.8.1 (b).

Convexity. Apply Definition 16.11.1 (b) with $\theta = \frac{1}{2}$ to $\mathbf{X}$ and $\mathbf{Y}$, then Lemma 20.8.1 (b) twice:

$$f\big(\tfrac{1}{2}(\mathbf{X}+\mathbf{Y})\big) \preceq \tfrac{1}{2}\big(\mathbf{U}^* f(\mathbf{M})\mathbf{U} + \mathbf{W}^*\mathbf{U}^* f(\mathbf{M})\mathbf{U}\mathbf{W}\big).$$

By Lemma 20.8.1 (c), $f(\mathbf{M}) = f(\mathbf{A}) \oplus f(0)\mathbf{I}_m$. The same block computation as before, now with $f(\mathbf{A})$ in place of $\mathbf{A}$ and $f(0)\mathbf{I}_m$ in place of $\mathbf{0}_m$, gives

$$\mathbf{U}^* f(\mathbf{M})\mathbf{U} = \begin{pmatrix} \mathbf{V}^* f(\mathbf{A})\mathbf{V} + f(0)\mathbf{D}_1^2 & * \\ * & * \end{pmatrix},$$

and averaging with its $\mathbf{W}$-conjugate again deletes the off-diagonal blocks. On the left, Lemma 20.8.1 (c) and $(*)$ give $f(\frac{1}{2}(\mathbf{X}+\mathbf{Y})) = f(\mathbf{V}^*\mathbf{A}\mathbf{V}) \oplus f(\mathbf{D}_2\mathbf{A}\mathbf{D}_2)$. So the inequality reads, between two block diagonal matrices,

$$f(\mathbf{V}^*\mathbf{A}\mathbf{V}) \oplus f(\mathbf{D}_2\mathbf{A}\mathbf{D}_2) \;\preceq\; \big(\mathbf{V}^* f(\mathbf{A})\mathbf{V} + f(0)\mathbf{D}_1^2\big) \oplus \mathbf{Z}$$

for some Hermitian $\mathbf{Z}$. The difference of the two sides is positive semidefinite, so its top-left $m \times m$ block is too, by Theorem 12.6.1 (a). Since $\mathbf{D}_1^2 = \mathbf{I}_m - \mathbf{V}^*\mathbf{V}$, that block inequality is the displayed statement of the theorem.

(a) If $f(0) \le 0$, then $f(0)(\mathbf{I}_m - \mathbf{V}^*\mathbf{V}) \preceq 0$, because $\mathbf{I}_m - \mathbf{V}^*\mathbf{V} \succeq 0$ and a non-positive multiple of a positive semidefinite matrix has non-positive quadratic form. Adding it can only decrease, so $\mathbf{V}^* f(\mathbf{A})\mathbf{V} + f(0)(\mathbf{I}_m - \mathbf{V}^*\mathbf{V}) \preceq \mathbf{V}^* f(\mathbf{A})\mathbf{V}$, and transitivity of $\preceq$ (Proposition 12.5.1) finishes.

(b) If $\mathbf{V}^*\mathbf{V} = \mathbf{I}_m$ the extra term is $\mathbf{0}$.

■

The special case worth remembering separately takes $\mathbf{V}$ to be a projection. It says that **an operator convex function commutes with compression, up to the right inequality**.

Corollary 20.8.6 — Compression

Let I be an interval with $0 \in I$, let $f\colon I \to \mathbb{R}$ be operator convex with $f(0) \le 0$, let $\mathbf{A} \in M_n(F)$ be Hermitian with $\operatorname{spec}(\mathbf{A}) \subseteq I$, and let $\mathbf{P} \in M_n(F)$ be the matrix of an orthogonal projection. Then $\operatorname{spec}(\mathbf{P}\mathbf{A}\mathbf{P}) \subseteq I$ and

$$f(\mathbf{P}\mathbf{A}\mathbf{P}) \;\preceq\; \mathbf{P} f(\mathbf{A})\mathbf{P}.$$

Proof. $\mathbf{P}$ is Hermitian with $\mathbf{P}^*\mathbf{P} = \mathbf{P}^2 = \mathbf{P} \preceq \mathbf{I}$, so $\mathbf{P}$ is a contraction (Definition 20.8.1). Apply Theorem 20.8.5 (a) with $\mathbf{V} = \mathbf{P}$, noting $\mathbf{P}^*\mathbf{A}\mathbf{P} = \mathbf{P}\mathbf{A}\mathbf{P}$.

■

Warning. **The condition $f(0) \le 0$ is not decoration.** Take $f(t) = t^2 + 1$, operator convex on $\mathbb{R}$ by Proposition 20.8.2 (a), with $f(0) = 1 > 0$. Take $\mathbf{A} = \mathbf{0}_n$ and $\mathbf{V} = \mathbf{0}_{n\times m}$, a contraction. Then $f(\mathbf{V}^*\mathbf{A}\mathbf{V}) = f(\mathbf{0}_m) = \mathbf{I}_m$ while $\mathbf{V}^* f(\mathbf{A})\mathbf{V} = \mathbf{0}$, so the conclusion of

Theorem 20.8.5 (a) fails as badly as it can. The full inequality of the theorem survives: its right-hand side is $\mathbf{0} + 1 \cdot \mathbf{I}_m = \mathbf{I}_m$, with equality.

Quick check. Why can the hypothesis "$\mathbf{V}$ is a contraction" not be dropped in Corollary 20.8.6 by rescaling — that is, why does the corollary for $\mathbf{P}$ not give a version for $c\mathbf{P}$ with $c > 1$?

Solution. Because both sides scale differently. For $f(t) = t^2$ and $\mathbf{V} = c\mathbf{I}$ the claimed inequality would read $c^4\mathbf{A}^2 \preceq c^2\mathbf{A}^2$, which fails for every $c > 1$ and every $\mathbf{A}$ with $\mathbf{A}^2 \neq \mathbf{0}$. The contraction hypothesis is what keeps the left-hand side from being inflated, and it enters the proof twice: it puts $\operatorname{spec}(\mathbf{V}^*\mathbf{A}\mathbf{V})$ back inside I, which is what makes $f(\mathbf{V}^*\mathbf{A}\mathbf{V})$ defined at all, and it gives the square roots of Lemma 20.8.4 something to be square roots of.

20.8.6 Where this sits

Two convexity statements about matrices are now on the table, and they are of very different strengths.

- §02's Theorem 20.2.8: for **every** convex f, the function $\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A})$ is convex on the Hermitian matrices with spectrum in I. This is a statement about one real number attached to the matrix.
- Operator convexity: for a much smaller class of f, the matrices themselves are ordered. Example (The Cube Is Convex and Not Operator Convex) shows t^3 in the first class and not the second.

The Hansen–Pedersen–Jensen inequality is the reason the smaller class is worth isolating. A trace inequality cannot be compressed: knowing $\operatorname{tr} f(\mathbf{A})$ says nothing about $\operatorname{tr} f(\mathbf{P}\mathbf{A}\mathbf{P})$, since the compression changes the eigenvalues in ways the trace does not track. What Corollary 20.8.6 compares is not the traces but the matrices, $f(\mathbf{P}\mathbf{A}\mathbf{P})$ with $\mathbf{P}f(\mathbf{A})\mathbf{P}$, and it is the step that later turns an operator convex function into an inequality between matrices of different sizes. Section 10 of this chapter adds $-\log t$ and $t \log t$ to the list of operator convex functions, and §11 uses the operator monotonicity of $t^{1/2}$ to build the geometric mean of two positive definite matrices.

20.8.7 Exercises

20.8.7.1 A. Check your understanding

Exercise A1.

(a) State what it means for $f\colon I \to \mathbb{R}$ to be operator convex, and say what the clause "for every n" ranges over.

(b) Explain why an operator convex function is convex, and name a convex function that is not operator convex.

(c) Decide whether the following is correct, and justify your answer: if f is operator convex on I and $c < 0$, then cf is operator convex on I.

(d) State the Hansen–Pedersen–Jensen inequality, and say which hypothesis fails for

$f(t) = t^2 + 1$.

(e) Is $t \mapsto -1/t$ operator convex on $(0, \infty)$? Is it operator concave there?

Solution.

(a) For every $n \geq 1$, all Hermitian $\mathbf{A}, \mathbf{B} \in M_n(F)$ with spectra in I and every $\theta \in [0, 1]$, $f(\theta\mathbf{A}+(1-\theta)\mathbf{B}) \preceq \theta f(\mathbf{A})+(1-\theta)f(\mathbf{B})$ (Definition 16.11.1 (b)). The clause ranges over all matrix sizes at once.

(b) Taking $n = 1$ turns the matrices into numbers and $\preceq$ into $\leq$, which is Definition 17.10.1. The function $t \mapsto t^3$ is convex on $[0, \infty)$ and not operator convex there (Example (The Cube Is Convex and Not Operator Convex)).

(c) Incorrect: Proposition 20.8.2 (a) requires $c \geq 0$. For $c = -1$ and $f(t) = t^2$, the claim would make $-t^2$ operator convex, that is t^2 operator concave; but Proposition 16.11.8 gives $\theta\mathbf{A}^2 + (1-\theta)\mathbf{B}^2 - (\theta\mathbf{A} + (1-\theta)\mathbf{B})^2 = \theta(1-\theta)(\mathbf{A}-\mathbf{B})^2$, which is non-zero for $\mathbf{A} \neq \mathbf{B}$ and $0 < \theta < 1$, so the reverse inequality fails.

(d) Theorem 20.8.5: for f operator convex on an interval containing 0, $\mathbf{A}$ Hermitian with spectrum in that interval and $\mathbf{V}$ a contraction, $f(\mathbf{V}^*\mathbf{A}\mathbf{V}) \preceq \mathbf{V}^* f(\mathbf{A})\mathbf{V} + f(0)(\mathbf{I} - \mathbf{V}^*\mathbf{V})$. The last term vanishes when $\mathbf{V}$ is an isometry, and when $f(0) \leq 0$ it is $\preceq \mathbf{0}$ and may be discarded, which leaves $f(\mathbf{V}^*\mathbf{A}\mathbf{V}) \preceq \mathbf{V}^* f(\mathbf{A})\mathbf{V}$ in both cases. For $f(t) = t^2 + 1$ the failing hypothesis is $f(0) \leq 0$.

(e) It is not operator convex: at $n = 1$ the scalar function $-1/t$ is not convex, since at 1, 3 and their midpoint 2 the value $-\frac{1}{2}$ exceeds the chord's $-\frac{2}{3}$. It **is** operator concave, by Theorem 20.8.3 (c).

20.8.7.2 B. Practice

Exercise B1: Which are operator convex?.

Determine which of the following functions are operator convex on the interval given. Justify your answer.

(i) $f(t) = 7 - 3t$ on $\mathbb{R}$.

(ii) $f(t) = 2t^2 + 5t - 1$ on $\mathbb{R}$.

(iii) $f(t) = \dfrac{4}{t+3}$ on $(0, \infty)$.

(iv) $f(t) = \dfrac{t}{t+3}$ on $(0, \infty)$.

(v) $f(t) = t^3$ on $[0, \infty)$.

Solution.

(i) Operator convex (and concave), by Theorem 20.8.3 (a).

(ii) Operator convex: it is 2 times t^2 plus the affine function $5t-1$, so Proposition 20.8.2 (a) applies with $c = 2 \geq 0$.

(iii) Operator convex, by Theorem 20.8.3 (d) with $c = 3$ and Proposition 20.8.2 (a) with the factor $4 \geq 0$.

(iv) Not operator convex; it is operator **concave** by Theorem 20.8.3 (d). Operator convexity would force ordinary convexity at $n = 1$, and $t/(t+3) = 1 - 3/(t+3)$

has second derivative $-6/(t+3)^3 < 0$ on $(0,\infty)$, so it is strictly concave there (Theorem 17.10.6).

(v) Not operator convex, by Example (The Cube Is Convex and Not Operator Convex).

Exercise B2: A dilation by hand.

Let $\mathbf{V} = \begin{pmatrix} \frac{1}{2} & 0 \\ 0 & 0 \end{pmatrix}$.

(a) Verify that $\mathbf{V}$ is a contraction and compute $\mathbf{D}_1 = (\mathbf{I}_2 - \mathbf{V}^*\mathbf{V})^{1/2}$ and $\mathbf{D}_2 = (\mathbf{I}_2 - \mathbf{V}\mathbf{V}^*)^{1/2}$.

(b) Write down the 4×4 matrix $\mathbf{U}$ of Lemma 20.8.4 and verify directly that its first column is a unit vector orthogonal to its third column.

Solution.

(a) $\mathbf{V}^*\mathbf{V} = \mathbf{V}\mathbf{V}^* = \operatorname{diag}(\frac{1}{4}, 0)$, so $\mathbf{I}_2 - \mathbf{V}^*\mathbf{V} = \operatorname{diag}(\frac{3}{4}, 1) \succeq 0$, and $\mathbf{V}$ is a contraction. Both $\mathbf{I}_2 - \mathbf{V}^*\mathbf{V}$ and $\mathbf{I}_2 - \mathbf{V}\mathbf{V}^*$ equal $\operatorname{diag}(\frac{3}{4}, 1)$, a diagonal matrix with non-negative entries, so

$$\mathbf{D}_1 = \mathbf{D}_2 = \operatorname{diag}\big(\tfrac{\sqrt{3}}{2},\, 1\big),$$

the unique positive semidefinite square root (Theorem 12.2.1).

(b) With the blocks in the order of the lemma,

$$\mathbf{U} = \begin{pmatrix} \frac{1}{2} & 0 & \frac{\sqrt{3}}{2} & 0 \\ 0 & 0 & 0 & 1 \\ \frac{\sqrt{3}}{2} & 0 & -\frac{1}{2} & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}.$$

Its first column is $(\frac{1}{2}, 0, \frac{\sqrt{3}}{2}, 0)$, of squared length $\frac{1}{4} + \frac{3}{4} = 1$. Its third column is $(\frac{\sqrt{3}}{2}, 0, -\frac{1}{2}, 0)$, and the inner product of the two is $\frac{1}{2} \cdot \frac{\sqrt{3}}{2} + \frac{\sqrt{3}}{2} \cdot (-\frac{1}{2}) = 0$.

Exercise B3: Compression of a square.

Let

$$\mathbf{A} = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}, \qquad \mathbf{P} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

Compute $(\mathbf{PAP})^2$ and $\mathbf{PA}^2\mathbf{P}$, and verify the inequality of Corollary 20.8.6 for $f(t) = t^2$. Hence state what the inequality says about the entry in position $(1,1)$.

Solution. $\mathbf{P}$ is the orthogonal projection onto $\operatorname{span}(\mathbf{e}_1)$, and $\mathbf{PAP} = \operatorname{diag}(2, 0)$, so $(\mathbf{PAP})^2 = \operatorname{diag}(4, 0)$. From $\mathbf{A}^2 = \left(\begin{smallmatrix} 5 & 3 \\ 3 & 2 \end{smallmatrix}\right)$ we get $\mathbf{PA}^2\mathbf{P} = \operatorname{diag}(5, 0)$. Hence

$$\mathbf{PA}^2\mathbf{P} - (\mathbf{PAP})^2 = \operatorname{diag}(1, 0) \;\succeq\; 0,$$

as Corollary 20.8.6 predicts for $f(t) = t^2$, which is operator convex with $f(0) = 0$. In position $(1,1)$ the inequality says $(\mathbf{A}^2)_{11} \geq (a_{11})^2$, that is $5 \geq 4$: the $(1,1)$ entry of $\mathbf{A}^2$ is $\sum_j |a_{1j}|^2$, which exceeds $|a_{11}|^2$ by the contribution of the off-diagonal entries.

20.8.7.3 C. Going deeper

Exercise C1: The square, without the dilation.

Let $\mathbf{A} \in M_n(F)$ be Hermitian and let $\mathbf{V} \in M_{n\times m}(F)$ be a contraction.

(a) Prove that $(\mathbf{V}^*\mathbf{A}\mathbf{V})^2 \preceq \mathbf{V}^*\mathbf{A}^2\mathbf{V}$ directly, without using Theorem 20.8.5.

(b) Which hypothesis of Theorem 20.8.5 does your proof use, and which does it not?

Hint for (a): insert $\mathbf{I} - \mathbf{V}\mathbf{V}^*$.

Solution.

(a) Compute the difference and factor it:

$$\mathbf{V}^*\mathbf{A}^2\mathbf{V} - (\mathbf{V}^*\mathbf{A}\mathbf{V})^2 = \mathbf{V}^*\mathbf{A}\mathbf{A}\mathbf{V} - \mathbf{V}^*\mathbf{A}\mathbf{V}\mathbf{V}^*\mathbf{A}\mathbf{V} = \mathbf{V}^*\mathbf{A}(\mathbf{I}_n - \mathbf{V}\mathbf{V}^*)\mathbf{A}\mathbf{V}.$$

As in the proof of Lemma 20.8.4, $\mathbf{I}_n - \mathbf{V}\mathbf{V}^* \succeq 0$ because $\mathbf{V}$ is a contraction. Writing $\mathbf{S} = \mathbf{A}\mathbf{V}$, the right-hand side is $\mathbf{S}^*(\mathbf{I}_n - \mathbf{V}\mathbf{V}^*)\mathbf{S}$, which is $\succeq 0$ by Proposition 12.1.2 (a). Hence $(\mathbf{V}^*\mathbf{A}\mathbf{V})^2 \preceq \mathbf{V}^*\mathbf{A}^2\mathbf{V}$.

(b) It uses the contraction hypothesis, in the single step $\mathbf{I}_n - \mathbf{V}\mathbf{V}^* \succeq 0$. It does not use $f(0) \le 0$ — but it does not need to, since $f(t) = t^2$ has $f(0) = 0$.

Exercise C2: Shrinking the matrix.

Let I be an interval with $0 \in I$, let f be operator convex on I with $f(0) \le 0$, and let $\mathbf{A} \in M_n(F)$ be Hermitian with $\operatorname{spec}(\mathbf{A}) \subseteq I$.

(a) Prove that $f(\theta\mathbf{A}) \preceq \theta f(\mathbf{A})$ for every $\theta \in [0, 1]$, assuming $\operatorname{spec}(\theta\mathbf{A}) \subseteq I$.

(b) Give an operator convex f with $f(0) > 0$ for which (a) fails, and say at which θ.

(c) Let $\mathbf{V} \in M_{n\times 1}(F)$ be a unit column vector and $g(t) = t^2 + 1$ on $\mathbb{R}$. Write out what Theorem 20.8.5 (b) says here, and verify it for $\mathbf{A} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ and $\mathbf{V} = \mathbf{e}_1$.

Hint for (a): a scalar multiple of the identity is a contraction when the scalar is small.

Solution.

(a) Put $\mathbf{V} = \sqrt{\theta}\,\mathbf{I}_n$, which is Hermitian with $\mathbf{V}^*\mathbf{V} = \theta\mathbf{I}_n \preceq \mathbf{I}_n$, so $\mathbf{V}$ is a contraction (Definition 20.8.1). Then $\mathbf{V}^*\mathbf{A}\mathbf{V} = \theta\mathbf{A}$ and $\mathbf{V}^* f(\mathbf{A})\mathbf{V} = \theta f(\mathbf{A})$. By Theorem 20.8.5 (a),

$$f(\theta\mathbf{A}) = f(\mathbf{V}^*\mathbf{A}\mathbf{V}) \;\preceq\; \mathbf{V}^* f(\mathbf{A})\mathbf{V} = \theta f(\mathbf{A}).$$

(b) Take $f(t) = t^2 + 1$, operator convex on $\mathbb{R}$ by Proposition 20.8.2 (a), with $f(0) = 1 > 0$. At $\theta = 0$ the claim reads $f(\mathbf{0}) \preceq \mathbf{0}$, that is $\mathbf{I}_n \preceq \mathbf{0}$, which is false. In fact it fails at every $\theta < 1$: the claim is $\theta^2\mathbf{A}^2 + \mathbf{I} \preceq \theta\mathbf{A}^2 + \theta\mathbf{I}$, which rearranges to $(1-\theta)\mathbf{I} \preceq (\theta - \theta^2)\mathbf{A}^2$, and for $\mathbf{A} = \mathbf{0}$ the right-hand side is $\mathbf{0}$ while the left-hand side is $\succ 0$.

(c) A unit column $\mathbf{V}$ satisfies $\mathbf{V}^*\mathbf{V} = (1) = \mathbf{I}_1$, so it is an isometry and (b) of the theorem applies with no condition on $g(0) = 1$. It says $g(\mathbf{V}^*\mathbf{A}\mathbf{V}) \preceq \mathbf{V}^* g(\mathbf{A})\mathbf{V}$, which for 1×1 matrices is the number inequality $(\mathbf{V}^*\mathbf{A}\mathbf{V})^2 + 1 \le \mathbf{V}^*(\mathbf{A}^2 + \mathbf{I})\mathbf{V}$.

With $\mathbf{V} = \mathbf{e}_1$: $\mathbf{e}_1^* \mathbf{A} \mathbf{e}_1 = 2$, so the left side is 5; and $\mathbf{A}^2 = \left(\begin{smallmatrix} 5 & 3 \\ 3 & 2 \end{smallmatrix}\right)$, so the right side is $5 + 1 = 6$. Indeed $5 \le 6$.

Exercise C3: What the trace does not see.

Let $\mathbf{A} = \operatorname{diag}(1, 0)$ and $\mathbf{B} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ be the matrices of Example (The Cube Is Convex and Not Operator Convex), and let $f(t) = t^3$ on $[0, \infty)$.

(a) Compute $\operatorname{tr}\big(\frac{1}{2}(\mathbf{A}^3 + \mathbf{B}^3)\big) - \operatorname{tr}\big(\big(\frac{1}{2}(\mathbf{A} + \mathbf{B})\big)^3\big)$, and say which theorem makes its sign predictable.

(b) The same defect matrix is indefinite. Explain, in one sentence, why (a) and that fact are consistent.

(c) Give a convex function g on $[0, \infty)$ for which the defect matrix at this pair $\mathbf{A}, \mathbf{B}$ is positive semidefinite, and name the reason.

Solution.

(a) From Example (The Cube Is Convex and Not Operator Convex) the defect is $\frac{1}{8}\left(\begin{smallmatrix} 22 & 18 \\ 18 & 14 \end{smallmatrix}\right)$, whose trace is $\frac{1}{8}(22 + 14) = \frac{9}{2} > 0$. Its sign is predictable from Theorem 20.2.8: $t \mapsto t^3$ is convex on $[0, \infty)$, so $\mathbf{A} \mapsto \operatorname{tr}(\mathbf{A}^3)$ is a convex function of the Hermitian matrix, and the defect of a convex function at a midpoint is ≥ 0.

(b) A Hermitian 2×2 matrix can have positive trace and a negative eigenvalue; the trace only sees the **sum** of the eigenvalues, and here they are approximately 4.55 and -0.055.

(c) Take $g(t) = t^2$. By Proposition 16.11.8 the defect equals $\frac{1}{4}(\mathbf{A} - \mathbf{B})^2$, a nonnegative multiple of the square of a Hermitian matrix, hence $\succeq 0$. Explicitly $\mathbf{A} - \mathbf{B} = \left(\begin{smallmatrix} -1 & -1 \\ -1 & -1 \end{smallmatrix}\right)$, so the defect is $\frac{1}{4}\left(\begin{smallmatrix} 2 & 2 \\ 2 & 2 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1/2 & 1/2 \\ 1/2 & 1/2 \end{smallmatrix}\right) \succeq 0$.

20.9 Loewner Matrices

Chapter 16 §11 left operator monotonicity as an infinite list of conditions: one for every matrix size, each quantified over all pairs of Hermitian matrices of that size. Nothing in that list can be checked. This section replaces the condition at size n by a condition on **numbers**: a single symmetric $n \times n$ matrix built out of f alone, at n chosen points, must be positive semidefinite. Two ingredients do the work — a formula for the derivative of $s \mapsto f(\mathbf{A} + s\mathbf{H})$, and the Schur product theorem of Chapter 12 §07. They are the elementary half of Loewner's theorem, and they are proved here in full.

Throughout, $F = \mathbb{R}$ **or** $F = \mathbb{C}$, every matrix whose spectrum is named is Hermitian, and I denotes an **interval** of real numbers with more than one point. The letter I is plain italic and is not the identity matrix $\mathbf{I}$. For $f\colon I \to \mathbb{R}$ and Hermitian $\mathbf{A}$ with $\operatorname{spec}(\mathbf{A}) \subseteq I$, the matrix $f(\mathbf{A})$ is the one built by the functional calculus of Chapter 11 §08 (Definition 11.8.2). We write $f \in C^1(I)$ to mean that f is differentiable on I, with one-sided derivatives at any endpoint belonging to I, and that f' is continuous on I.

20.9.1 Slopes between two points

Operator monotonicity compares $f(\mathbf{A})$ with $f(\mathbf{B})$, and the difference of two values of f is what a slope measures. Everything below is assembled from slopes.

The divided difference of f at two points is the slope of the chord joining them, and at a repeated point it is the slope of the tangent.

Definition 20.9.1 — Divided Difference

Let $f\colon I \to \mathbb{R}$ be differentiable. For $s, t \in I$, the **divided difference** of f is

$$f[s,t] := \begin{cases} \dfrac{f(s)-f(t)}{s-t}, & s \neq t, \\ f'(t), & s = t. \end{cases}$$

In words: for two distinct points it is the slope of the chord through $(s, f(s))$ and $(t, f(t))$; the second clause is the value that makes the first one continuous as s approaches t, which is exactly what the derivative is. It is symmetric, $f[s,t] = f[t,s]$, since swapping s and t negates both numerator and denominator, and it is additive in f: $(f+g)[s,t] = f[s,t] + g[s,t]$ and $(cf)[s,t] = c\,f[s,t]$.

Examples.

- $f(t) = \alpha + \beta t$: then $f[s,t] = \beta$ for all s, t, including $s = t$. The divided difference of an affine function is constant — it has one slope.
- $f(t) = t^2$: then $f[s,t] = (s^2 - t^2)/(s-t) = s + t$ for $s \neq t$, and $f[t,t] = 2t = t + t$. So $f[s,t] = s + t$ throughout.
- $f(t) = t^k$ for $k \geq 1$: dividing $s^k - t^k$ by $s - t$ gives $f[s,t] = \sum_{p=0}^{k-1} s^p t^{k-1-p}$, which at $s = t$ reads $kt^{k-1} = f'(t)$, so again one formula covers both clauses.
- $f(t) = -1/t$ on $(0, \infty)$: then $-1/s + 1/t = (s-t)/(st)$, so $f[s,t] = 1/(st)$, and at $s = t$ this is $1/t^2 = f'(t)$.
- $f(t) = \sqrt{t}$ on $(0, \infty)$: rationalizing, $(\sqrt{s} - \sqrt{t})/(s-t) = 1/(\sqrt{s} + \sqrt{t})$, and at $s = t$ this is $1/(2\sqrt{t}) = f'(t)$.

Non-example by minimal change. Drop differentiability and keep continuity: for $f(t) = |t|$ on $\mathbb{R}$ the first clause still makes sense, but $f[0,0]$ has no value, since the chord slopes $f[s,0] = \operatorname{sgn}(s)$ do not settle down as $s \to 0$. Differentiability fills in the diagonal; continuous differentiability makes the filled-in function continuous.

Lemma 20.9.1 — Divided Differences Are Continuous

Let $f \in C^1(I)$. If (s_k) and (t_k) are sequences in I with $s_k \to s_0 \in I$ and $t_k \to t_0 \in I$, then $f[s_k, t_k] \to f[s_0, t_0]$. In particular, for each fixed $\alpha \in I$ the function $t \mapsto f[\alpha, t]$ is continuous on I.

Proof. Case 1: $s_0 \neq t_0$. For large k we have $s_k \neq t_k$, since $s_k - t_k \to s_0 - t_0 \neq 0$. So $f[s_k, t_k] = (f(s_k) - f(t_k))/(s_k - t_k)$ for large k, and the algebra of limits applies, the denominator having non-zero limit: the quotient tends to $(f(s_0) - f(t_0))/(s_0 - t_0) = f[s_0, t_0]$, using that f is continuous because it is differentiable.

Case 2: $s_0 = t_0$. Let $\varepsilon > 0$. Since f' is continuous at t_0, there is $\delta > 0$ with $|f'(c) - f'(t_0)| < \varepsilon$ for every $c \in I$ with $|c - t_0| < \delta$. Take k large enough that $|s_k - t_0| < \delta$ and $|t_k - t_0| < \delta$. If $s_k = t_k$ then $f[s_k, t_k] = f'(s_k)$, which is within ε of $f'(t_0)$. If $s_k \neq t_k$, then by the mean value theorem (A6), applied to f on the interval with endpoints s_k and t_k — an interval contained in I — there is c_k strictly between them with

$$f[s_k, t_k] = \frac{f(s_k) - f(t_k)}{s_k - t_k} = f'(c_k).$$

Then $|c_k - t_0| < \delta$, so again $|f[s_k, t_k] - f'(t_0)| < \varepsilon$. Since $f[t_0, t_0] = f'(t_0)$, this proves the claim.

■

20.9.2 The Loewner matrix

Collect the slopes between all pairs drawn from a list of points, and a matrix appears.

The Loewner matrix of f at n points is the table of all the chord slopes between them.

Definition 20.9.2 — Loewner Matrix

Let $f\colon I \to \mathbb{R}$ be differentiable and let $t_1, \dots, t_n \in I$. The **Loewner matrix** of f at these points is

$$L_f(t_1, \dots, t_n) \coloneqq \big(f[t_i, t_j]\big)_{i,j=1}^{n} \in M_n(\mathbb{R}).$$

Every entry is real and the matrix is **symmetric**, because the divided difference is; its diagonal entries are $f'(t_1), \dots, f'(t_n)$. A real symmetric matrix is Hermitian, so it makes sense to ask whether it is positive semidefinite — the only question this section asks about it. The points need not be distinct; if $t_i = t_j$ then rows i and j coincide.

Examples. All four use the divided differences computed above.

- $f(t) = \alpha + \beta t$: every entry is β, so $L_f = \beta \mathbf{J}$, where $\mathbf{J}$ is the all-ones matrix. Since $\mathbf{J} = \mathbf{1}\mathbf{1}^{\top}$ is positive semidefinite, $L_f \succeq 0$ exactly when $\beta \geq 0$ — which is precisely when the affine function is operator monotone, by Proposition 16.11.2 one way and Proposition 16.11.1 the other.
- $f(t) = -1/t$ on $(0, \infty)$: the (i, j) entry is $1/(t_i t_j)$, so $L_f = \mathbf{d}\mathbf{d}^{\top}$ with $\mathbf{d} = (1/t_1, \dots, 1/t_n)$. A matrix of the form $\mathbf{d}\mathbf{d}^{\top}$ is positive semidefinite, so **every** Loewner matrix of $-1/t$ is $\succeq 0$, at every n. Compare Proposition 16.11.3.
- $f(t) = -1/(t + c)$ with $c \geq 0$: the same computation with $t_i + c$ in place of t_i gives the rank-one matrix with entries $1/((t_i + c)(t_j + c))$, again $\succeq 0$. Compare Corollary 16.11.5.
- $f(t) = \sqrt{t}$ on $(0, \infty)$: the (i, j) entry is $1/(\sqrt{t_i} + \sqrt{t_j})$. A matrix of the form $(1/(x_i + x_j))$ with $x_i > 0$ is called a **Cauchy matrix**.

Non-example by minimal change. In the first example take $\alpha = 0$ and $\beta = 1$, so that $f(t) = t$ and $L_f = \mathbf{J} \succeq 0$. Raise the exponent from 1 to 2, and positivity is lost at once.

Example. (The Loewner Matrix of the Square)

Let $f(t) = t^2$ on $[0, \infty)$ and let $s \neq t$ be points of $[0, \infty)$. Compute $L_f(s, t)$ and decide whether it is positive semidefinite.

Solution. Since $f[s, t] = s + t$ and $f'(t) = 2t$,

$$L_f(s,t) = \begin{pmatrix} 2s & s+t \\ s+t & 2t \end{pmatrix}, \qquad \det L_f(s,t) = 4st - (s+t)^2 = -(s-t)^2.$$

The determinant is a principal minor, and it is < 0 because $s \neq t$. By Theorem 12.1.4 (e), $L_f(s, t)$ is not positive semidefinite — it is indefinite, its determinant being negative. So the square already fails at $n = 2$, at **every** pair of distinct points, which is the numerical shadow of Example (Squaring does not preserve the Loewner order).

Example. (A Cauchy Matrix)

Let $f(t) = \sqrt{t}$ on $(0, \infty)$ and take the points $1, 4, 9$. Compute $L_f(1, 4, 9)$ and decide whether it is positive semidefinite.

Solution. The square roots are $1, 2, 3$, and the (i, j) entry is $1/(\sqrt{t_i} + \sqrt{t_j})$, so

$$L_f(1,4,9) = \begin{pmatrix} \frac{1}{2} & \frac{1}{3} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \\ \frac{1}{4} & \frac{1}{5} & \frac{1}{6} \end{pmatrix}.$$

The first two leading principal minors are

$$\tfrac{1}{2} \qquad \text{and} \qquad \tfrac{1}{2} \cdot \tfrac{1}{4} - \left(\tfrac{1}{3}\right)^2 = \tfrac{1}{8} - \tfrac{1}{9} = \tfrac{1}{72}.$$

For the third, expand along the first row. The three minors are

$$\tfrac{1}{24} - \tfrac{1}{25} = \tfrac{1}{600}, \qquad \tfrac{1}{18} - \tfrac{1}{20} = \tfrac{1}{180}, \qquad \tfrac{1}{15} - \tfrac{1}{16} = \tfrac{1}{240},$$

so, with the alternating signs,

$$\det L_f(1,4,9) = \tfrac{1}{2} \cdot \tfrac{1}{600} - \tfrac{1}{3} \cdot \tfrac{1}{180} + \tfrac{1}{4} \cdot \tfrac{1}{240} = \tfrac{1}{1200} - \tfrac{1}{540} + \tfrac{1}{960}.$$

Over the common denominator 43200 the three terms are 36, 80 and 45, and $36 - 80 + 45 = 1$, so $\det L_f(1, 4, 9) = 1/43200$. All three leading principal minors are positive, so $L_f(1, 4, 9) \succ 0$ by Sylvester's criterion (Theorem 12.1.5 (d)), and in particular $\succeq 0$.

The contrast between the two examples is the point of the section: $\sqrt{t}$ is operator monotone and t^2 is not, and the Loewner matrices see the difference with no matrix inequality tested. The theorem below says this is no coincidence.

Warning. **One size at a time.** A Loewner matrix is built from **one** choice of n points. Positivity for one choice says nothing about another, and positivity at all choices of n points is not by itself a statement about $n + 1$ points: $f(t) = t^2$ has $L_f(t) = (2t) \succeq 0$ at every point of $[0, \infty)$, and already at two points it fails (Example (The Loewner Matrix of the Square)). The criterion below is an equivalence *size by size*: it matches the $n \times n$

Loewner matrices with order-preservation on $n \times n$ matrices, and operator monotonicity is the conjunction of all of these.

Since the criterion works one size at a time, the property it characterizes needs a name.

Definition 20.9.3 — Monotone of Order n

Let $n \geq 1$ and let $f\colon I \to \mathbb{R}$. Then f is **monotone of order n on I** if, for all Hermitian $\mathbf{A}, \mathbf{B} \in M_n(F)$ whose spectra lie in I,

$$\mathbf{A} \succeq \mathbf{B} \quad \Longrightarrow \quad f(\mathbf{A}) \succeq f(\mathbf{B}).$$

Comparing with Definition 16.11.1 (a): **f is operator monotone on I exactly when it is monotone of order n for every $n \geq 1$.** Order 1 is plain monotonicity (Proposition 16.11.1), and order 2 is already a strictly stronger demand: $t \mapsto t^2$ is increasing on $[0, \infty)$ and fails at $n = 2$ (Example (Squaring does not preserve the Loewner order)). Whether each further order is in turn strictly stronger than the one before is not decided here.

20.9.3 Differentiating a matrix function

The link between the Loewner matrix and the order is a derivative, and the derivative comes out of one exact algebraic identity. Write both matrices in their spectral resolutions, insert the identity on both sides, and the difference of the two functional calculi factors through the difference of the matrices, with divided differences as the coefficients.

Lemma 20.9.2 — The Two-Resolution Identity

Let $f\colon I \to \mathbb{R}$ be differentiable and let $\mathbf{A}, \mathbf{B} \in M_n(F)$ be Hermitian with spectra in I. Write the spectral resolutions

$$\mathbf{A} = \sum_i \alpha_i \mathbf{P}_i, \qquad \mathbf{B} = \sum_k \beta_k \mathbf{Q}_k$$

with α_i the distinct eigenvalues of $\mathbf{A}$ and β_k those of $\mathbf{B}$ (Theorem 11.8.1). Then

$$f(\mathbf{B}) - f(\mathbf{A}) = \sum_{i,k} f[\alpha_i, \beta_k]\, \mathbf{P}_i (\mathbf{B} - \mathbf{A}) \mathbf{Q}_k.$$

Idea. The resolutions of the identity $\sum_i \mathbf{P}_i = \mathbf{I}$ and $\sum_k \mathbf{Q}_k = \mathbf{I}$ can be inserted on the two sides of any matrix, which splits it into $i \times k$ pieces. On the piece $\mathbf{P}_i \cdot \mathbf{Q}_k$, the matrix $\mathbf{A}$ acts as the number α_i from the left and $\mathbf{B}$ acts as β_k from the right. So both $f(\mathbf{B}) - f(\mathbf{A})$ and $\mathbf{B} - \mathbf{A}$ become numbers on each piece, namely $f(\beta_k) - f(\alpha_i)$ and $\beta_k - \alpha_i$, and the ratio of those two numbers is the divided difference.

Proof. By Theorem 11.8.1 (c), $\sum_i \mathbf{P}_i = \mathbf{I}$ and $\sum_k \mathbf{Q}_k = \mathbf{I}$. By Theorem 11.8.1 (e), $\mathbf{P}_i \mathbf{A} = \alpha_i \mathbf{P}_i$ and $\mathbf{B}\mathbf{Q}_k = \beta_k \mathbf{Q}_k$; and $\mathbf{P}_i f(\mathbf{A}) = f(\alpha_i)\mathbf{P}_i$, $f(\mathbf{B})\mathbf{Q}_k = f(\beta_k)\mathbf{Q}_k$ follow

from Definition 11.8.2 together with Theorem 11.8.1 (b). Hence

$$f(\mathbf{B}) - f(\mathbf{A}) = \sum_{i,k} \mathbf{P}_i \big(f(\mathbf{B}) - f(\mathbf{A})\big)\mathbf{Q}_k$$
$$= \sum_{i,k} \big(f(\beta_k) - f(\alpha_i)\big)\mathbf{P}_i\mathbf{Q}_k,$$

and in the same way

$$\mathbf{P}_i(\mathbf{B} - \mathbf{A})\mathbf{Q}_k = (\beta_k - \alpha_i)\,\mathbf{P}_i\mathbf{Q}_k.$$

Fix i and k. If $\alpha_i \neq \beta_k$, then by Definition 20.9.1

$$\big(f(\beta_k) - f(\alpha_i)\big)\mathbf{P}_i\mathbf{Q}_k = f[\alpha_i, \beta_k](\beta_k - \alpha_i)\mathbf{P}_i\mathbf{Q}_k = f[\alpha_i, \beta_k]\,\mathbf{P}_i(\mathbf{B} - \mathbf{A})\mathbf{Q}_k.$$

If $\alpha_i = \beta_k$, then both $f(\beta_k) - f(\alpha_i)$ and $\beta_k - \alpha_i$ are 0, so both sides of that equation are the zero matrix and it holds as well. Summing over i and k gives the identity.

■

The identity is exact, with no limit in it. To turn it into a derivative we let $\mathbf{B}$ approach $\mathbf{A}$, which needs the functional calculus to be continuous. It is, and the proof shows what a mixed pair of eigenbases is for.

Lemma 20.9.3 — Continuity of the Functional Calculus

Let $J = [a, b]$ be a closed bounded interval, let $g\colon J \to \mathbb{R}$ be continuous and let $n \geq 1$. For every $\varepsilon > 0$ there is $\eta > 0$ such that all Hermitian $\mathbf{X}, \mathbf{Y} \in M_n(F)$ with spectra in J and $\|\mathbf{X} - \mathbf{Y}\|_F < \eta$ satisfy

$$\|g(\mathbf{X}) - g(\mathbf{Y})\|_F < \varepsilon.$$

Idea. Diagonalize $\mathbf{X}$ and $\mathbf{Y}$ separately, and read both $g(\mathbf{X}) - g(\mathbf{Y})$ and $\mathbf{X} - \mathbf{Y}$ in the **mixed** basis, one eigenbasis on the left and the other on the right. In that basis the two matrices have entries $(g(a_i) - g(b_k))w_{ik}$ and $(a_i - b_k)w_{ik}$ with the same w_{ik}, so they differ only in how the scalar factor is built. Where a_i and b_k are close, continuity of g makes the first factor small; where they are far apart, the second factor is large and can pay for the first. The Frobenius norm is the right yardstick because it is computed from the entries and is unchanged by a unitary factor on either side.

Proof. By the extreme value theorem (A4), g is bounded on the compact interval J; let $M = \max_{t \in J} |g(t)|$. If $M = 0$, then g is identically 0 and there is nothing to prove, so assume $M > 0$.

Step 1: g is uniformly continuous on J. Suppose not. Then there is $\varepsilon_0 > 0$ such that for every $k \geq 1$ there are $a_k, b_k \in J$ with $|a_k - b_k| \leq 1/k$ and $|g(a_k) - g(b_k)| \geq \varepsilon_0$. By compactness (A3), a subsequence a_{k_j} converges to some $a \in J$; then $b_{k_j} \to a$ too, since $|b_{k_j} - a_{k_j}| \to 0$. Continuity of g at a gives $g(a_{k_j}) \to g(a)$ and $g(b_{k_j}) \to g(a)$, so $|g(a_{k_j}) - g(b_{k_j})| \to 0$, contradicting the lower bound ε_0.

Step 2: the mixed basis. Let $\mathbf{X}$ and $\mathbf{Y}$ be Hermitian with spectra in J. By Corollary 11.4.3 over $\mathbb{C}$, or Corollary 11.5.2 over $\mathbb{R}$, there are unitary $\mathbf{U}, \mathbf{V} \in M_n(F)$ whose columns $\mathbf{u}_1, \dots, \mathbf{u}_n$ and $\mathbf{v}_1, \dots, \mathbf{v}_n$ are orthonormal eigenbases, with $\mathbf{X}\mathbf{u}_i = a_i\mathbf{u}_i$ and $\mathbf{Y}\mathbf{v}_k = b_k\mathbf{v}_k$, all $a_i, b_k \in J$. Put $w_{ik} = \mathbf{u}_i^*\mathbf{v}_k$, the entries of the unitary matrix $\mathbf{W} = \mathbf{U}^*\mathbf{V}$;

then $\sum_{i,k}|w_{ik}|^2 = \|\mathbf{W}\|_F^2 = n$.

Write $\mathbf{X} = \sum_j \mu_j \mathbf{P}_j$ for the spectral resolution. Exactly one μ_j equals a_i, and $\mathbf{u}_i$ lies in its eigenspace, so $\mathbf{P}_j\mathbf{u}_i = \mathbf{u}_i$ for that j and $\mathbf{P}_j\mathbf{u}_i = \mathbf{0}$ for the others, the eigenspaces being orthogonal (Theorem 11.8.1 (a)). Hence $g(\mathbf{X})\mathbf{u}_i = g(a_i)\mathbf{u}_i$ by Definition 11.8.2, and likewise $g(\mathbf{Y})\mathbf{v}_k = g(b_k)\mathbf{v}_k$; since $g(a_i)$ is real and $g(\mathbf{X})$ is Hermitian, also $\mathbf{u}_i^* g(\mathbf{X}) = g(a_i)\mathbf{u}_i^*$. Hence the (i,k) entry of $\mathbf{U}^*\big(g(\mathbf{X}) - g(\mathbf{Y})\big)\mathbf{V}$ is

$$\mathbf{u}_i^*\big(g(\mathbf{X}) - g(\mathbf{Y})\big)\mathbf{v}_k = \big(g(a_i) - g(b_k)\big)w_{ik},$$

and the same computation with g replaced by the identity function gives $\mathbf{u}_i^*(\mathbf{X}-\mathbf{Y})\mathbf{v}_k = (a_i - b_k)w_{ik}$. By Lemma 11.11.1,

$$\|g(\mathbf{X}) - g(\mathbf{Y})\|_F^2 = \sum_{i,k}|g(a_i) - g(b_k)|^2|w_{ik}|^2,$$
$$\|\mathbf{X} - \mathbf{Y}\|_F^2 = \sum_{i,k}|a_i - b_k|^2|w_{ik}|^2.$$

Step 3: the split. Let $\varepsilon > 0$. By Step 1 there is $\delta > 0$ with $|g(a) - g(b)| \le \varepsilon/(2\sqrt{n})$ whenever $a, b \in J$ and $|a-b| < \delta$. Split the index pairs (i,k) into those with $|a_i - b_k| < \delta$ and those with $|a_i - b_k| \ge \delta$. The first group contributes at most

$$\frac{\varepsilon^2}{4n}\sum_{i,k}|w_{ik}|^2 = \frac{\varepsilon^2}{4n}\cdot n = \frac{\varepsilon^2}{4}.$$

In the second group $|g(a_i) - g(b_k)| \le 2M \le (2M/\delta)|a_i - b_k|$, so that group contributes at most $(2M/\delta)^2\|\mathbf{X} - \mathbf{Y}\|_F^2$. Therefore

$$\|g(\mathbf{X}) - g(\mathbf{Y})\|_F^2 \;\le\; \frac{\varepsilon^2}{4} + \Big(\frac{2M}{\delta}\Big)^2\|\mathbf{X} - \mathbf{Y}\|_F^2.$$

Take $\eta = \varepsilon\delta/(4M) > 0$. If $\|\mathbf{X} - \mathbf{Y}\|_F < \eta$, the second term is less than $\varepsilon^2/4$, so $\|g(\mathbf{X}) - g(\mathbf{Y})\|_F^2 < \varepsilon^2/2 < \varepsilon^2$. This proves the lemma.

■

Now the theorem. With the two lemmas in hand it is bookkeeping.

Theorem 20.9.4 — The Derivative of a Matrix Function

Let $f \in C^1(I)$, let $\mathbf{A}, \mathbf{H} \in M_n(F)$ be Hermitian, and suppose there are $s_0 > 0$ and a closed bounded interval $J \subseteq I$ with

$$\operatorname{spec}(\mathbf{A} + s\mathbf{H}) \subseteq J \qquad \text{for every real } s \text{ with } |s| < s_0.$$

Then the matrix-valued function $\mathbf{G}(s) \coloneqq f(\mathbf{A}+s\mathbf{H})$, defined for $|s| < s_0$, is differentiable at $s = 0$ in the sense of Definition 15.6.1, and:

(a) If $\mathbf{A} = \operatorname{diag}(t_1, \dots, t_n)$, then

$$\mathbf{G}'(0) = L_f(t_1, \dots, t_n) \circ \mathbf{H},$$

the Hadamard product of Definition 12.7.1.

(b) In general, if $\mathbf{A} = \mathbf{U}\mathbf{D}\mathbf{U}^*$ with $\mathbf{U}$ unitary and $\mathbf{D} = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$, then

$$\mathbf{G}'(0) = \mathbf{U}\Big(L_f(\lambda_1, \dots, \lambda_n) \circ (\mathbf{U}^*\mathbf{H}\mathbf{U})\Big)\mathbf{U}^*.$$

Remark. The hypothesis on J is automatic when I is **open**. Write $I = (c, d)$ with $-\infty \le c < d \le \infty$. Then $c < \lambda_n(\mathbf{A}) \le \lambda_1(\mathbf{A}) < d$, so there is $\rho > 0$ with $[\lambda_n(\mathbf{A}) - \rho, \lambda_1(\mathbf{A}) + \rho] \subseteq I$; taking $s_0 = \rho/(\|\mathbf{H}\|_2 + 1)$ and J that closed interval works, because $|\lambda_i(\mathbf{A} + s\mathbf{H}) - \lambda_i(\mathbf{A})| \le |s|\|\mathbf{H}\|_2 < \rho$ by Corollary 16.3.6.

Idea. Apply Lemma 20.9.2 with $\mathbf{B} = \mathbf{A} + s\mathbf{H}$. The right-hand side is a sum over pairs (eigenvalue of $\mathbf{A}$, eigenvalue of $\mathbf{B}$), and the sum over the second index is nothing but a functional calculus: freezing the first argument of the divided difference turns $f[\alpha_i, \cdot]$ into an ordinary continuous function g_i, and $\sum_k g_i(\beta_k)\mathbf{Q}_k$ is $g_i(\mathbf{B})$. So the identity collapses to

$$f(\mathbf{A} + s\mathbf{H}) - f(\mathbf{A}) = s \sum_i \mathbf{P}_i \, \mathbf{H} \, g_i(\mathbf{A} + s\mathbf{H}),$$

with the factor s already pulled out. Now let $s \to 0$: by Lemma 20.9.3, $g_i(\mathbf{A} + s\mathbf{H}) \to g_i(\mathbf{A})$, and the limit of the sum is the Hadamard product in disguise.

Proof. Write $\mathbf{A} = \sum_i \alpha_i \mathbf{P}_i$ for the spectral resolution, with $\alpha_1, \dots, \alpha_r$ the distinct eigenvalues of $\mathbf{A}$, and put $\mathbf{B}_s = \mathbf{A} + s\mathbf{H}$, so that $\mathbf{G}(s) = f(\mathbf{B}_s)$, for $|s| < s_0$. For each i define

$$g_i \colon J \to \mathbb{R}, \qquad g_i(x) = f[\alpha_i, x],$$

which is continuous by Lemma 20.9.1, since $f \in C^1(I)$ and $J \subseteq I$.

Step 1: an exact formula. Let $\mathbf{B}_s = \sum_k \beta_k(s)\mathbf{Q}_k(s)$ be the spectral resolution of $\mathbf{B}_s$. By Lemma 20.9.2 with $\mathbf{B} = \mathbf{B}_s$, and $\mathbf{B}_s - \mathbf{A} = s\mathbf{H}$,

$$\begin{aligned} f(\mathbf{B}_s) - f(\mathbf{A}) &= \sum_{i,k} f[\alpha_i, \beta_k(s)] \, \mathbf{P}_i(s\mathbf{H})\mathbf{Q}_k(s) \\ &= s \sum_i \mathbf{P}_i \mathbf{H} \Big(\sum_k g_i(\beta_k(s))\mathbf{Q}_k(s) \Big) = s \sum_i \mathbf{P}_i \, \mathbf{H} \, g_i(\mathbf{B}_s), \end{aligned}$$

the last equality being Definition 11.8.2 applied to g_i and $\mathbf{B}_s$, whose spectrum lies in J, the domain of g_i.

Step 2: the limit. Since $\|\mathbf{B}_s - \mathbf{A}\|_F = |s| \, \|\mathbf{H}\|_F \to 0$ as $s \to 0$, and since $\mathbf{A}$ and every $\mathbf{B}_s$ are Hermitian with spectra in J, Lemma 20.9.3 gives $\|g_i(\mathbf{B}_s) - g_i(\mathbf{A})\|_F \to 0$ for each i. By Definition 11.8.2,

$$g_i(\mathbf{A}) = \sum_j g_i(\alpha_j)\mathbf{P}_j = \sum_j f[\alpha_i, \alpha_j] \, \mathbf{P}_j.$$

Dividing the formula of Step 1 by $s \neq 0$ and letting $s \to 0$, the algebra of limits (applied entry by entry, and using $|m_{pq}| \le \|\mathbf{M}\|_F$ for any matrix) gives

$$\frac{\mathbf{G}(s) - \mathbf{G}(0)}{s} \longrightarrow \sum_{i,j} f[\alpha_i, \alpha_j] \, \mathbf{P}_i \mathbf{H} \mathbf{P}_j.$$

Entrywise, this says exactly that each entry of $\mathbf{G}$ is differentiable at $s = 0$, with derivative the corresponding entry of the right-hand side. So $\mathbf{G}'(0)$ exists in the sense of Definition 15.6.1 and equals $\sum_{i,j} f[\alpha_i, \alpha_j]\mathbf{P}_i\mathbf{H}\mathbf{P}_j$.

Step 3: reading it as a Hadamard product. Let $\mathbf{A} = \mathbf{U}\mathbf{D}\mathbf{U}^*$ with $\mathbf{U}$ unitary, $\mathbf{D} = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$, and let $\mathbf{u}_1, \dots, \mathbf{u}_n$ be the columns of $\mathbf{U}$, so $\mathbf{A}\mathbf{u}_p = \lambda_p \mathbf{u}_p$. Each $\mathbf{P}_i$ is the orthogonal projection onto the eigenspace of α_i, which is spanned by those $\mathbf{u}_p$ with $\lambda_p = \alpha_i$; hence $\mathbf{P}_i = \sum_{p:\lambda_p=\alpha_i} \mathbf{u}_p\mathbf{u}_p^*$, and these sums partition $\{1, \dots, n\}$. Therefore

$$\sum_{i,j} f[\alpha_i, \alpha_j]\mathbf{P}_i\mathbf{H}\mathbf{P}_j = \sum_{p,q} f[\lambda_p, \lambda_q]\, \mathbf{u}_p\mathbf{u}_p^*\mathbf{H}\mathbf{u}_q\mathbf{u}_q^*.$$

Now $\mathbf{u}_p^*\mathbf{H}\mathbf{u}_q = (\mathbf{U}^*\mathbf{H}\mathbf{U})_{pq}$, and for any $\mathbf{M} \in M_n(F)$ we have $\mathbf{U}\mathbf{M}\mathbf{U}^* = \sum_{p,q} m_{pq}\mathbf{u}_p\mathbf{u}_q^*$. Taking $\mathbf{M} = L_f(\lambda_1, \dots, \lambda_n) \circ (\mathbf{U}^*\mathbf{H}\mathbf{U})$, whose (p, q) entry is $f[\lambda_p, \lambda_q](\mathbf{U}^*\mathbf{H}\mathbf{U})_{pq}$, the displayed sum is $\mathbf{U}\mathbf{M}\mathbf{U}^*$. This proves (b), and (a) is the case $\mathbf{U} = \mathbf{I}$.

■

Remark. Two sanity checks. For $f(t) = t$ the Loewner matrix is $\mathbf{J}$, the identity for $\circ$, and the formula returns $\mathbf{H}$ — as it must, since $f(\mathbf{A} + s\mathbf{H}) = \mathbf{A} + s\mathbf{H}$. And the diagonal entries of (a) are $f'(t_i)h_{ii}$: to first order the i-th eigenvalue of $\operatorname{diag}(t_1, \dots, t_n) + s\mathbf{H}$ moves by h_{ii} when the t_i are distinct (Theorem 19.11.2, as computed in Chapter 19 §11), and the chain rule then moves f of it by $f'(t_i)h_{ii}$. What the theorem adds is the **off-diagonal** part, where the eigenvectors turn, and there the chord slope $f[t_i, t_j]$ appears in place of the tangent slope.

Quick check. Take $n = 2$, $\mathbf{A} = \operatorname{diag}(t_1, t_2)$ with $t_1 \neq t_2$, and $\mathbf{H} = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$. What does Theorem 20.9.4 (a) predict, and what does it say about the eigenvalues of $\mathbf{A} + s\mathbf{H}$ to first order?

Solution. The Hadamard product with $\mathbf{H}$ keeps only the off-diagonal entries, so the derivative is $\left(\begin{smallmatrix} 0 & f[t_1,t_2] \\ f[t_1,t_2] & 0 \end{smallmatrix}\right)$. Its diagonal is zero, which matches the eigenvalue statement: $h_{11} = h_{22} = 0$, so to first order neither eigenvalue of $\mathbf{A} + s\mathbf{H}$ moves. All of the first-order change in $f(\mathbf{A} + s\mathbf{H})$ is in the eigenvectors, and the coefficient that measures it is the chord slope between t_1 and t_2, not a derivative.

20.9.4 The criterion

Everything is now in place. One direction walks along the segment from $\mathbf{B}$ to $\mathbf{A}$, using the Schur product theorem to keep the derivative positive semidefinite; the other reads the derivative off in a single well-chosen direction.

Theorem 20.9.5 — Loewner's Matrix Criterion

Let I be an interval with more than one point, let $f \in C^1(I)$ and let $n \geq 1$. The following are equivalent.

(i) f is monotone of order n on I.

(ii) $L_f(t_1, \dots, t_n) \succeq 0$ for all $t_1, \dots, t_n \in I$.

Idea. For (ii) $\Rightarrow$ (i): walk from $\mathbf{B}$ to $\mathbf{A}$ along the segment $\mathbf{B}_s = \mathbf{B} + s(\mathbf{A} - \mathbf{B})$, and watch the number $\varphi(s) = \langle f(\mathbf{B}_s)\mathbf{x}, \mathbf{x}\rangle$ for a fixed $\mathbf{x}$. Its derivative is, in the eigenbasis of $\mathbf{B}_s$, the quadratic form of a Hadamard product of two positive semidefinite matrices: the Loewner matrix, positive by hypothesis, and the direction $\mathbf{A} - \mathbf{B}$, positive because $\mathbf{A} \succeq \mathbf{B}$. The Schur product theorem says that such a product is positive semidefinite, so $\varphi' \geq 0$, and the mean value theorem does the rest.

For (i) $\Rightarrow$ (ii): the derivative formula turns order-preservation into $L_f \circ \mathbf{H} \succeq 0$ for every $\mathbf{H} \succeq 0$. Choose the one $\mathbf{H}$ that leaves L_f alone, namely the all-ones matrix $\mathbf{J} = \mathbf{1}\mathbf{1}^\top$, which is positive semidefinite and is the identity for $\circ$.

Proof. **(ii) $\Rightarrow$ (i).** Let $\mathbf{A}, \mathbf{B} \in M_n(F)$ be Hermitian with spectra in I and $\mathbf{A} \succeq \mathbf{B}$. Put $\mathbf{H} = \mathbf{A} - \mathbf{B} \succeq 0$ and $\mathbf{B}_s = \mathbf{B} + s\mathbf{H}$ for $s \in [0, 1]$. For such s, both $\mathbf{A} - \mathbf{B}_s = (1 - s)\mathbf{H}$ and $\mathbf{B}_s - \mathbf{B} = s\mathbf{H}$ are $\succeq 0$, so $\mathbf{A} \succeq \mathbf{B}_s \succeq \mathbf{B}$ and Corollary 16.2.4 gives

$$\lambda_i(\mathbf{B}) \;\leq\; \lambda_i(\mathbf{B}_s) \;\leq\; \lambda_i(\mathbf{A}) \qquad (i = 1, \dots, n).$$

Hence $\operatorname{spec}(\mathbf{B}_s) \subseteq J := [\lambda_n(\mathbf{B}), \lambda_1(\mathbf{A})]$ for every $s \in [0, 1]$, and $J \subseteq I$ because its two endpoints are eigenvalues of $\mathbf{B}$ and of $\mathbf{A}$, hence lie in I, and I is an interval.

Fix $\mathbf{x} \in F^n$ and put $\varphi(s) = \langle f(\mathbf{B}_s)\mathbf{x}, \mathbf{x}\rangle$ for $s \in [0, 1]$, a real number because $f(\mathbf{B}_s)$ is Hermitian (Theorem 11.8.3 (c)).

φ is continuous on $[0, 1]$. We have $\|\mathbf{B}_s - \mathbf{B}_{s'}\|_F = |s - s'|\|\mathbf{H}\|_F$, so Lemma 20.9.3 applied to f on J makes $s \mapsto f(\mathbf{B}_s)$ continuous in the Frobenius norm, and $|\langle \mathbf{M}\mathbf{x}, \mathbf{x}\rangle| \leq \|\mathbf{M}\|_F\|\mathbf{x}\|^2$ transfers this to φ.

$\varphi'(s) \geq 0$ for $0 < s < 1$. Fix such an s and put $s_0 = \min(s, 1 - s) > 0$. For $|\sigma| < s_0$ we have $\mathbf{B}_s + \sigma\mathbf{H} = \mathbf{B}_{s+\sigma}$ with $s + \sigma \in (0, 1)$, so its spectrum lies in J. Thus Theorem 20.9.4 applies to the pair $\mathbf{B}_s, \mathbf{H}$. Write $\mathbf{B}_s = \mathbf{U}\mathbf{D}\mathbf{U}^*$ with $\mathbf{U}$ unitary and $\mathbf{D} = \operatorname{diag}(\lambda_1(\mathbf{B}_s), \dots, \lambda_n(\mathbf{B}_s))$, and set

$$\mathbf{C} = L_f\big(\lambda_1(\mathbf{B}_s), \dots, \lambda_n(\mathbf{B}_s)\big), \qquad \mathbf{M} = \mathbf{U}^*\mathbf{H}\mathbf{U}.$$

Then $\mathbf{C} \succeq 0$ by hypothesis (ii), since the $\lambda_i(\mathbf{B}_s)$ lie in $J \subseteq I$, and $\mathbf{M} \succeq 0$ by Proposition 12.1.2 (a). By the Schur product theorem (Theorem 12.7.2 (a)), $\mathbf{C} \circ \mathbf{M} \succeq 0$. A quadratic form $\langle \mathbf{X}\mathbf{x}, \mathbf{x}\rangle$ is a fixed linear combination of the entries of $\mathbf{X}$, so an entrywise derivative of a matrix-valued function differentiates it; hence φ is differentiable at s with

$$\varphi'(s) = \langle \mathbf{U}(\mathbf{C} \circ \mathbf{M})\mathbf{U}^*\mathbf{x}, \mathbf{x}\rangle = \langle (\mathbf{C} \circ \mathbf{M})\mathbf{y}, \mathbf{y}\rangle \;\geq\; 0,$$

where $\mathbf{y} = \mathbf{U}^*\mathbf{x}$.

Conclusion. Let $0 < a < b < 1$. By the mean value theorem (A6) applied to φ on $(0, 1)$, there is c between a and b with $\varphi(b) - \varphi(a) = \varphi'(c)(b - a) \geq 0$. Letting $a \to 0^+$ and $b \to 1^-$ and using the continuity of φ on $[0, 1]$, we get $\varphi(1) - \varphi(0) \geq 0$, that is

$$\langle f(\mathbf{A})\mathbf{x}, \mathbf{x}\rangle \;\geq\; \langle f(\mathbf{B})\mathbf{x}, \mathbf{x}\rangle.$$

As $\mathbf{x}$ was arbitrary, $f(\mathbf{A}) \succeq f(\mathbf{B})$ by Definition 12.5.1.

(i) ⇒ (ii). Suppose first that $t_1, \dots, t_n$ all lie in the interior of I, an open interval (c, d). Put

$$\mathbf{A} = \operatorname{diag}(t_1, \dots, t_n), \qquad \mathbf{H} = \mathbf{J} = \mathbf{1}\mathbf{1}^{\top},$$

so $\mathbf{H} \succeq 0$. Let $\rho > 0$ be small enough that $[\min_i t_i - \rho, \max_i t_i + \rho] \subseteq (c, d)$; this is possible because $c < \min_i t_i \le \max_i t_i < d$. Put $s_0 = \rho/(\|\mathbf{H}\|_2 + 1)$ and $J = [\min_i t_i - \rho, \max_i t_i + \rho]$. By Corollary 16.3.6, $\operatorname{spec}(\mathbf{A} + s\mathbf{H}) \subseteq J \subseteq I$ for $|s| < s_0$, so Theorem 20.9.4 applies.

For $0 < s < s_0$ we have $(\mathbf{A} + s\mathbf{H}) - \mathbf{A} = s\mathbf{H} \succeq 0$, and both matrices have spectra in I, so (i) gives $f(\mathbf{A} + s\mathbf{H}) \succeq f(\mathbf{A})$, that is

$$\frac{f(\mathbf{A} + s\mathbf{H}) - f(\mathbf{A})}{s} \;\succeq\; 0.$$

For each fixed $\mathbf{x}$ the number $\langle \cdot\, \mathbf{x}, \mathbf{x} \rangle$ of the left-hand side is ≥ 0, and it converges as $s \to 0^+$ to the quadratic form of the derivative, by Theorem 20.9.4 (a); a non-strict inequality survives a limit, so the derivative is $\succeq 0$. But the derivative is $L_f(t_1, \dots, t_n) \circ \mathbf{J} = L_f(t_1, \dots, t_n)$, because every entry of $\mathbf{J}$ is 1, so $\mathbf{J}$ is the identity for the Hadamard product (Definition 12.7.1). Hence $L_f(t_1, \dots, t_n) \succeq 0$.

Now let $t_1, \dots, t_n$ be arbitrary points of I. Since I has more than one point, it has an interior point m; put $t_i^{(k)} = (1 - 1/k)t_i + (1/k)m$ for $k \ge 1$. Each $t_i^{(k)}$ lies in I, being a convex combination of two of its points, and it is an **interior** point: if $(m-\varepsilon, m+\varepsilon) \subseteq I$, then every point within ε/k of $t_i^{(k)}$ is of the form $(1 - 1/k)t_i + (1/k)(m + u)$ with $|u| < \varepsilon$, hence lies in I. Also $t_i^{(k)} \to t_i$. By the case just proved, $L_f(t_1^{(k)}, \dots, t_n^{(k)}) \succeq 0$ for every k, and by Lemma 20.9.1 each entry converges to the corresponding entry of $L_f(t_1, \dots, t_n)$. For each $\mathbf{x}$, the quadratic forms are ≥ 0 and converge to the quadratic form of $L_f(t_1, \dots, t_n)$, which is therefore ≥ 0. This proves the theorem.

■

Remark. The hypothesis $f \in C^1(I)$ enters in three places: it gives the diagonal entries $f'(t_i)$ of the Loewner matrix a meaning, it makes Lemma 20.9.1 available, and through that lemma it supplies the continuous functions g_i that the derivative formula needs. Whether it can be dropped is not settled here: a monotone-of-order-n function is not obviously differentiable. The next section returns to that point for operator monotone functions, where the answer turns out to be yes, at the price of an imported theorem.

Taking $n = 1$ recovers Proposition 16.11.1: $L_f(t) = (f'(t))$, so monotone of order 1 means $f' \ge 0$, which for a C^1 function is the same as increasing, by the mean value theorem (A6). The first genuinely new case is $n = 2$, and there the criterion is two inequalities about numbers.

Corollary 20.9.6 — The Criterion at Order Two

Let I be an interval with more than one point and let $f \in C^1(I)$. Then f is monotone of order 2 on I if and only if

$$f'(t) \ge 0 \;\text{ for all } t \in I, \qquad \text{and} \qquad f[s,t]^2 \le f'(s)f'(t) \;\text{ for all } s, t \in I.$$

Proof. By Theorem 20.9.5 with $n = 2$, monotonicity of order 2 is equivalent to $L_f(s,t) \succeq 0$ for all $s, t \in I$. The matrix

$$L_f(s,t) = \begin{pmatrix} f'(s) & f[s,t] \\ f[s,t] & f'(t) \end{pmatrix}$$

is real symmetric, and its principal minors are the two diagonal entries $f'(s), f'(t)$ and the determinant $f'(s)f'(t) - f[s,t]^2$. By Theorem 12.1.4 (e), $L_f(s,t) \succeq 0$ if and only if all three are ≥ 0. Ranging over all $s, t \in I$, these are exactly the two displayed conditions; the case $s = t$ of the second is the tautology $f'(t)^2 \leq f'(t)^2$.

■

In words: f **increases, and the slope of every chord is at most the geometric mean of the slopes of the tangents at its ends.** Three of Chapter 16 §11's examples can now be re-derived, and its non-example refuted, without touching a matrix.

- $f(t) = -1/t$ on $(0,\infty)$: $f'(t) = 1/t^2 \geq 0$, and $f[s,t] = 1/(st)$, so $f[s,t]^2 = 1/(s^2t^2) = f'(s)f'(t)$. The condition holds with **equality** everywhere, which is the numerical form of the fact that L_f has rank one.
- $f(t) = \sqrt{t}$ on $(0,\infty)$: $f'(t) = 1/(2\sqrt{t}) \geq 0$, and $f[s,t] = 1/(\sqrt{s} + \sqrt{t})$, so

$$f'(s)f'(t) - f[s,t]^2 = \frac{(\sqrt{s}+\sqrt{t})^2 - 4\sqrt{st}}{4\sqrt{st}\,(\sqrt{s}+\sqrt{t})^2} = \frac{(\sqrt{s}-\sqrt{t})^2}{4\sqrt{st}\,(\sqrt{s}+\sqrt{t})^2} \;\geq\; 0.$$

- $f(t) = \alpha + \beta t$: $f' = \beta$ and $f[s,t] = \beta$, so the conditions are $\beta \geq 0$ and $\beta^2 \leq \beta^2$.
- $f(t) = t^2$ on $[0,\infty)$: $f' = 2t \geq 0$, but $f[s,t]^2 - f'(s)f'(t) = (s+t)^2 - 4st = (s-t)^2 > 0$ for $s \neq t$. So t^2 is **not** monotone of order 2, and therefore not operator monotone. This is Example (Squaring does not preserve the Loewner order) again, now with the failure located at every pair of distinct points rather than at one pair of matrices.

Warning. **Order two is not "increasing and concave".** The second condition of Corollary 20.9.6 looks like a concavity statement and is not one, in either direction. The function $f(t) = t - t^2/2$ on $(0,1)$ is increasing ($f' = 1 - t > 0$) and concave, yet

$$f'(s)f'(t) - f[s,t]^2 = (1-s)(1-t) - \Big(1 - \frac{s+t}{2}\Big)^2 = st - \Big(\frac{s+t}{2}\Big)^2,$$

which equals $-\big((s-t)/2\big)^2$, negative for $s \neq t$; so f is not monotone of order 2. In the other direction, $g(t) = -\log(1-t)$ on $(0,1)$ is increasing and **convex** and *is* monotone of order 2. Writing $a = 1-s$ and $b = 1-t$, so that $s - t = b - a$, we have $g'(s)g'(t) = 1/(ab)$ and $g[s,t] = (\log b - \log a)/(b-a)$, so the second condition reads

$$(\log b - \log a)^2 \;\leq\; \frac{(b-a)^2}{ab},$$

an inequality about the logarithm alone; Exercise (C2: The logarithm at order two) proves it.

20.9.5 What this gives, and what it does not

The criterion is an equivalence, so it reads either way. Right to left it manufactures operator monotone functions: exhibit positive semidefinite Loewner matrices at every order and the function preserves the order at every size. Left to right it refutes them cheaply, since one bad pair of points kills order 2 and hence operator monotonicity.

What it does not give is the classification. The conditions "$L_f(t_1, \dots, t_n) \succeq 0$ for all n and all points" are still infinitely many, and turning them into the integral representation of Theorem 16.11.9 is the analytic half of Loewner's theorem — the business of the next section, and the one place where the chapter spends an imported theorem. What is proved here needs no analysis beyond three items of the chapter's list: the mean value theorem (A6), which turns a non-negative derivative into monotonicity along the segment; and, inside Lemma 20.9.3, the extreme value theorem (A4), which bounds g, and the compactness of a closed bounded interval (A3), which makes g uniformly continuous.

20.9.6 Exercises

20.9.6.1 A. Check your understanding

Exercise A1.

(a) Define $f[s,t]$ for $s = t$, and say what hypothesis on f the definition needs.

(b) Write down $L_f(t_1, t_2, t_3)$ in terms of divided differences, and say why it is Hermitian.

(c) State Theorem 20.9.5, and say which of its two directions uses the Schur product theorem.

(d) Decide whether the following is correct, and justify your answer: if $L_f(t_1, t_2) \succeq 0$ for all $t_1, t_2 \in I$, then f is operator monotone on I.

(e) What does Theorem 20.9.4 give when $\mathbf{H}$ is diagonal?

Solution.

(a) $f[t,t] = f'(t)$ (Definition 20.9.1); the definition needs f to be differentiable on I, and the continuity statement Lemma 20.9.1 needs f' continuous as well.

(b) It is the 3×3 matrix whose (i,j) entry is $f[t_i, t_j]$, with diagonal $f'(t_1), f'(t_2), f'(t_3)$. It is real and symmetric, because f is real-valued and $f[s,t] = f[t,s]$; a real symmetric matrix is Hermitian.

(c) For $f \in C^1(I)$ and $n \geq 1$: f is monotone of order n on I if and only if $L_f(t_1, \dots, t_n) \succeq 0$ for all $t_1, \dots, t_n \in I$. The Schur product theorem (Theorem 12.7.2) is used in the direction (ii) $\Rightarrow$ (i), to show that the derivative along the segment is positive semidefinite.

(d) Incorrect. Positivity of all 2×2 Loewner matrices gives monotonicity of order 2 only (Corollary 20.9.6); operator monotonicity demands every order. The warning after Example (A Cauchy Matrix) makes the point, and Definition 16.11.1 (a) quantifies over all n.

(e) If $\mathbf{H} = \operatorname{diag}(h_1, \dots, h_n)$ and $\mathbf{A} = \operatorname{diag}(t_1, \dots, t_n)$, then $L_f \circ \mathbf{H}$ is the diagonal matrix $\operatorname{diag}(f'(t_1)h_1, \dots, f'(t_n)h_n)$: the two matrices commute, the problem is

scalar in each coordinate, and the answer is the ordinary chain rule n times.

20.9.6.2 B. Practice

Exercise B1: Loewner matrices by hand.

Compute $L_f(1,2)$ for each of the following, and determine whether it is positive semidefinite. Justify your answer.

(i) $f(t) = 4 + 3t$ on $\mathbb{R}$.
(ii) $f(t) = t^2$ on $(0,\infty)$.
(iii) $f(t) = -1/t$ on $(0,\infty)$.
(iv) $f(t) = \sqrt{t}$ on $(0,\infty)$, at the points 1 and 4 instead.

Solution.

(i) Every entry is 3, so $L_f(1,2) = 3\mathbf{J} = \left(\begin{smallmatrix} 3 & 3 \\ 3 & 3 \end{smallmatrix}\right)$. Its principal minors are $3, 3$ and 0, all ≥ 0, so it is $\succeq 0$ (Theorem 12.1.4 (e)).

(ii) $f'(t) = 2t$ and $f[1,2] = 3$, so $L_f(1,2) = \left(\begin{smallmatrix} 2 & 3 \\ 3 & 4 \end{smallmatrix}\right)$, with determinant $8 - 9 = -1 < 0$. Not positive semidefinite.

(iii) $f'(t) = 1/t^2$ and $f[1,2] = 1/2$, so $L_f(1,2) = \left(\begin{smallmatrix} 1 & 1/2 \\ 1/2 & 1/4 \end{smallmatrix}\right)$, with determinant $\frac{1}{4} - \frac{1}{4} = 0$ and diagonal entries > 0. Positive semidefinite, of rank one; indeed it is $\mathbf{d}\mathbf{d}^\top$ with $\mathbf{d} = (1, \frac{1}{2})$.

(iv) $f'(t) = 1/(2\sqrt{t})$ and $f[1,4] = 1/(1+2) = \frac{1}{3}$, so $L_f(1,4) = \left(\begin{smallmatrix} 1/2 & 1/3 \\ 1/3 & 1/4 \end{smallmatrix}\right)$, with determinant $\frac{1}{8} - \frac{1}{9} = \frac{1}{72} > 0$ and positive diagonal. Positive definite, and in particular $\succeq 0$; it is the top-left corner of the matrix of Example (A Cauchy Matrix).

Exercise B2: A derivative, two ways.

Let $\mathbf{A} = \operatorname{diag}(1,4)$, let $\mathbf{H} = \left(\begin{smallmatrix} 1 & 2 \\ 2 & 3 \end{smallmatrix}\right)$ and let $f(t) = t^2$ on $(0,\infty)$.

(a) Compute $L_f(1,4) \circ \mathbf{H}$.
(b) Expand $(\mathbf{A} + s\mathbf{H})^2$ and differentiate at $s = 0$ directly. Check that the two answers agree.

Solution.

(a) $L_f(1,4) = \left(\begin{smallmatrix} 2 & 5 \\ 5 & 8 \end{smallmatrix}\right)$, so

$$L_f(1,4) \circ \mathbf{H} = \begin{pmatrix} 2\cdot 1 & 5\cdot 2 \\ 5\cdot 2 & 8\cdot 3 \end{pmatrix} = \begin{pmatrix} 2 & 10 \\ 10 & 24 \end{pmatrix}.$$

(b) $(\mathbf{A} + s\mathbf{H})^2 = \mathbf{A}^2 + s(\mathbf{A}\mathbf{H} + \mathbf{H}\mathbf{A}) + s^2\mathbf{H}^2$, so the derivative at $s = 0$ is $\mathbf{A}\mathbf{H} + \mathbf{H}\mathbf{A}$. Now

$$\mathbf{A}\mathbf{H} = \begin{pmatrix} 1 & 2 \\ 8 & 12 \end{pmatrix}, \qquad \mathbf{H}\mathbf{A} = \begin{pmatrix} 1 & 8 \\ 2 & 12 \end{pmatrix}, \qquad \mathbf{A}\mathbf{H} + \mathbf{H}\mathbf{A} = \begin{pmatrix} 2 & 10 \\ 10 & 24 \end{pmatrix},$$

which agrees with (a). In general $(\mathbf{AH}+\mathbf{HA})_{ij} = (t_i+t_j)h_{ij}$ for diagonal $\mathbf{A}$, and t_i+t_j is exactly the divided difference of t^2.

Exercise B3: Refuting order two.

For each function, use Corollary 20.9.6 to decide whether it is monotone of order 2 on the interval given. Justify your answer.

(i) $f(t) = t/(t+1)$ on $(0,\infty)$.
(ii) $f(t) = t^2 - 6t$ on $(0,1)$.
(iii) $f(t) = 2t - 1/t$ on $(0,\infty)$.
(iv) $f(t) = t + t^2$ on $(0,\infty)$.

Solution.

(i) Monotone of order 2. Here $f(t) = 1 - 1/(t+1)$, so $f'(t) = 1/(t+1)^2 \geq 0$ and, by the computation for $-1/(t+c)$ with $c=1$, $f[s,t] = 1/((s+1)(t+1))$. Hence $f[s,t]^2 = f'(s)f'(t)$, with equality. (In fact the Loewner matrices of every order are rank one and $\succeq 0$, which recovers Corollary 16.11.5.)

(ii) Not monotone of order 2 — indeed it fails already at order 1, since $f'(t) = 2t-6 < 0$ on $(0,1)$, so the first condition fails.

(iii) Monotone of order 2. Here $f'(t) = 2 + 1/t^2 > 0$ and $f[s,t] = 2 + 1/(st)$, by additivity of divided differences and the two computations after Definition 20.9.1. So

$$f'(s)f'(t) - f[s,t]^2 = \frac{2}{s^2} + \frac{2}{t^2} - \frac{4}{st} = 2\Big(\frac{1}{s} - \frac{1}{t}\Big)^2 \geq 0,$$

the terms 4 and $1/(s^2t^2)$ canceling between the two products.

(iv) Not monotone of order 2. Here $f'(t) = 1 + 2t > 0$ and $f[s,t] = 1 + s + t$, so

$$\begin{aligned} f'(s)f'(t) - f[s,t]^2 &= (1+2s)(1+2t) - (1+s+t)^2 \\ &= 4st - (s+t)^2 = -(s-t)^2, \end{aligned}$$

which is < 0 for $s \neq t$. Adding the operator monotone function t to the non-monotone t^2 does not repair it.

20.9.6.3 C. Going deeper

Exercise C1: Powers, directly.

Let $k \geq 1$, let $\mathbf{A} = \operatorname{diag}(t_1,\dots,t_n)$ and let $\mathbf{H} \in M_n(F)$ be Hermitian.

(a) Expand $(\mathbf{A} + s\mathbf{H})^k$ and show that the coefficient of s is $\sum_{p+q=k-1} \mathbf{A}^p\mathbf{H}\mathbf{A}^q$, the sum being over integers $p, q \geq 0$.

(b) Compute the (i,j) entry of that matrix and identify it with $f[t_i,t_j]h_{ij}$ for $f(t) = t^k$.

(c) Hence prove Theorem 20.9.4 (a) for every polynomial f, without using Lemma 20.9.3.

Solution.

(a) Expanding the product $(\mathbf{A}+s\mathbf{H})(\mathbf{A}+s\mathbf{H})\cdots(\mathbf{A}+s\mathbf{H})$ of k factors and keeping the order of every product, the terms are indexed by the choice of $\mathbf{A}$ or $s\mathbf{H}$ in each factor. The terms with no $\mathbf{H}$ give $\mathbf{A}^k$; the terms with exactly one $\mathbf{H}$, in position $p+1$, give $s\,\mathbf{A}^p\mathbf{H}\mathbf{A}^{k-1-p}$ for $p=0,\dots,k-1$; the remaining terms carry a factor s^m with $m\ge 2$. So

$$(\mathbf{A}+s\mathbf{H})^k=\mathbf{A}^k+s\sum_{p+q=k-1}\mathbf{A}^p\mathbf{H}\mathbf{A}^q+s^2\mathbf{R}(s)$$

with $\mathbf{R}$ a matrix whose entries are polynomials in s.

(b) Since $\mathbf{A}^p=\operatorname{diag}(t_1^p,\dots,t_n^p)$, the matrix $\mathbf{A}^p\mathbf{H}\mathbf{A}^q$ has (i,j) entry $t_i^p h_{ij} t_j^q$. Summing,

$$\Big(\sum_{p+q=k-1}\mathbf{A}^p\mathbf{H}\mathbf{A}^q\Big)_{ij}=h_{ij}\sum_{p=0}^{k-1}t_i^p t_j^{k-1-p}=h_{ij}\,f[t_i,t_j],$$

the last equality by the third example after Definition 20.9.1, which covers $t_i=t_j$ as well.

(c) Each entry of $(\mathbf{A}+s\mathbf{H})^k$ is a polynomial in s, so it is differentiable at $s=0$, and by (a) and (b) its derivative there is $f[t_i,t_j]h_{ij}$, that is, the (i,j) entry of $L_f(t_1,\dots,t_n)\circ\mathbf{H}$. By Theorem 11.8.3 (a) the functional calculus of t^k is the k-th power, so this is the assertion for $f(t)=t^k$. For a general polynomial $f=\sum_k c_k t^k$, both $\mathbf{A}\mapsto f(\mathbf{A})$ and $f\mapsto L_f$ are linear in f (Theorem 11.8.3 (b) and the additivity of divided differences), so the identity for the powers gives it for f.

Exercise C2: The logarithm at order two.

(a) Prove that $r-1/r-2\log r\ge 0$ for every $r\ge 1$.

(b) Deduce that $\log$ is monotone of order 2 on $(0,\infty)$.

(c) Deduce that $f(t)=-\log(1-t)$ is monotone of order 2 on $(0,1)$, and verify that f is convex there.

Hint for (a): differentiate, and recognize a square.

Solution.

(a) Let $h(r)=r-1/r-2\log r$ on $[1,\infty)$. Then $h(1)=0$ and, for $r>0$,

$$h'(r)=1+\frac{1}{r^2}-\frac{2}{r}=\Big(1-\frac{1}{r}\Big)^2\ \ge\ 0.$$

For $r>1$, the mean value theorem (A6) gives $h(r)-h(1)=h'(c)(r-1)$ for some $c\in(1,r)$, and both factors are ≥ 0. Hence $h(r)\ge 0$.

(b) By Corollary 20.9.6 with $f=\log$ we must check $f'(t)=1/t\ge 0$, which holds on $(0,\infty)$, and

$$\Big(\frac{\log s-\log t}{s-t}\Big)^2\ \le\ \frac{1}{st}\qquad(s\ne t),$$

the case $s=t$ being the tautology. Both sides are unchanged by swapping s and t, so assume $s>t>0$ and write $s=tr^2$ with $r>1$. Then $\log s-\log t=2\log r$,

while

$$\frac{s-t}{\sqrt{st}} = \frac{t(r^2-1)}{tr} = r - \frac{1}{r}.$$

Both $2\log r$ and $r - 1/r$ are ≥ 0, and (a) says $2\log r \leq r - 1/r$. Squaring the inequality between non-negative numbers gives $(\log s - \log t)^2 \leq (s-t)^2/(st)$, which is the required inequality after dividing by $(s-t)^2 > 0$.

(c) Put $a = 1 - s$ and $b = 1 - t$ for $s, t \in (0,1)$, so $a, b \in (0,1)$ and $s - t = b - a$. Then $f'(t) = 1/(1-t)$, so $f'(s)f'(t) = 1/(ab)$, and

$$f[s,t] = \frac{-\log(1-s) + \log(1-t)}{s-t} = \frac{\log b - \log a}{b-a},$$

which is the divided difference of log at a and b. By (b) its square is at most $1/(ab) = f'(s)f'(t)$, and $f' > 0$, so Corollary 20.9.6 applies. Finally $f''(t) = 1/(1-t)^2 > 0$, so f is convex on $(0,1)$ by Theorem 17.10.6. So an increasing **convex** function can be monotone of order 2.

Exercise C3: Orders are nested.

Let $1 \leq m \leq n$ and let $f\colon I \to \mathbb{R}$; in (b) and (c) assume in addition that $f \in C^1(I)$, so that the Loewner matrices are defined and Theorem 20.9.5 applies.

(a) Prove that if f is monotone of order n on I, then it is monotone of order m on I.

(b) Give the corresponding statement about Loewner matrices, and prove it directly from Definition 20.9.2, without using Theorem 20.9.5.

(c) Explain why (a) and (b) together mean that a single failing pair of points rules out operator monotonicity at every order $n \geq 2$.

Hint for (a): pad with a scalar block.

Solution.

(a) Let $\mathbf{A}, \mathbf{B} \in M_m(F)$ be Hermitian with spectra in I, $\mathbf{A} \succeq \mathbf{B}$. Fix $c \in I$ and put

$$\widetilde{\mathbf{A}} = \mathbf{A} \oplus c\mathbf{I}_{n-m}, \qquad \widetilde{\mathbf{B}} = \mathbf{B} \oplus c\mathbf{I}_{n-m},$$

both Hermitian in $M_n(F)$ with spectra in I. Their difference is $(\mathbf{A} - \mathbf{B}) \oplus \mathbf{0}$, whose quadratic form at $(\mathbf{x}, \mathbf{y})$ is $\langle (\mathbf{A} - \mathbf{B})\mathbf{x}, \mathbf{x}\rangle \geq 0$, so $\widetilde{\mathbf{A}} \succeq \widetilde{\mathbf{B}}$. By hypothesis $f(\widetilde{\mathbf{A}}) \succeq f(\widetilde{\mathbf{B}})$. By Lemma 20.8.1 (c), $f(\widetilde{\mathbf{A}}) = f(\mathbf{A}) \oplus f(c)\mathbf{I}_{n-m}$ and likewise for $\mathbf{B}$, so the difference is $(f(\mathbf{A}) - f(\mathbf{B})) \oplus \mathbf{0}$. Evaluating its quadratic form at $(\mathbf{x}, \mathbf{0})$ gives $\langle (f(\mathbf{A}) - f(\mathbf{B}))\mathbf{x}, \mathbf{x}\rangle \geq 0$ for every $\mathbf{x} \in F^m$, that is $f(\mathbf{A}) \succeq f(\mathbf{B})$.

(b) If $L_f(t_1, \ldots, t_n) \succeq 0$ for all $t_1, \ldots, t_n \in I$, then $L_f(t_1, \ldots, t_m) \succeq 0$ for all $t_1, \ldots, t_m \in I$. Indeed, given $t_1, \ldots, t_m$, pad the list with any $t_{m+1}, \ldots, t_n \in I$; then $L_f(t_1, \ldots, t_m)$ is the leading principal $m \times m$ submatrix of $L_f(t_1, \ldots, t_n)$, because the (i,j) entry of each is $f[t_i, t_j]$ for $i, j \leq m$. A principal submatrix of a positive semidefinite matrix is positive semidefinite, since its quadratic form is the quadratic form of the big matrix at vectors supported on those coordinates (compare the proof of Theorem 12.1.4).

(c) By (b), a pair $s, t \in I$ with $L_f(s,t) \not\succeq 0$ forces $L_f(t_1, \ldots, t_n) \not\succeq 0$ for the padded list at every $n \geq 2$, so by Theorem 20.9.5 f is monotone of no order $n \geq 2$. Equivalently,

> by (a), failure at order 2 propagates upward — which is why Corollary 20.9.6 is the cheapest refutation available.

20.10 Loewner's Theorem

Chapter 16 §11 stated Loewner's theorem, said four times that this chapter would prove it, and named the one thing it was missing. Section 9 supplied the elementary half: a continuously differentiable function is monotone of order n exactly when every Loewner matrix of size n built from it is positive semidefinite (Theorem 20.9.5). What is left is to turn that infinite family of conditions into a single formula, and to run the formula back. Turning it into a formula is the one thing this book does not prove; running it back costs about a page of integration, which we build first.

Throughout, $F = \mathbb{R}$ **or** $F = \mathbb{C}$, every matrix whose eigenvalues are indexed is Hermitian, and $f(\mathbf{A})$ is the functional calculus of Definition 11.8.2. The letter I denotes an **interval** of real numbers, not the identity matrix $\mathbf{I}$, as in Chapter 16 §11. Three things from the analysis list of Chapter 15's introduction are used: completeness (A1), monotone convergence (A2) and the compactness of closed bounded sets (A3). Everything imported beyond those is named where it appears.

20.10.1 Integrating a matrix-valued function

Chapter 16 §11 read the integral formula of Theorem 16.11.9 (ii) and said what stopped it there:

> What this book lacks is the analysis that carries the Loewner order through an integral, which is not on the list (A1)–(A6) in Chapter 15's introduction.

That analysis is one definition and one lemma. It is not a theory of integration; it is the least that makes the sentence "an integral of positive semidefinite matrices is positive semidefinite" mean something.

A **tagged partition** of a compact interval $[a,b]$ is a list of division points $a = s_0 < s_1 < \cdots < s_N = b$ together with **tags** $\tau_i \in [s_{i-1}, s_i]$; we call the whole package P. Its **mesh** is $\max_i (s_i - s_{i-1})$. For $\mathbf{M}\colon [a,b] \to M_{p\times q}(\mathbb{C})$ the associated **Riemann sum** is

$$S(\mathbf{M}, P) := \sum_{i=1}^{N} \mathbf{M}(\tau_i)\,(s_i - s_{i-1}).$$

Call $\mathbf{M}$ **continuous** when each of its pq entries is a continuous complex-valued function of s; by Corollary 15.2.4 this is the same as continuity for any norm on $M_{p\times q}(\mathbb{C})$.

Proposition 20.10.1 — Riemann Sums of a Continuous Matrix Function Converge

Let $\mathbf{M}\colon [a,b] \to M_{p\times q}(\mathbb{C})$ be continuous. Then there is a matrix $J \in M_{p\times q}(\mathbb{C})$ such that $S(\mathbf{M}, P_k) \to J$ for **every** sequence (P_k) of tagged partitions of $[a,b]$ whose meshes tend

to 0.

Idea. Two Riemann sums of small mesh are close because each is close to the sum over their common refinement, and on a refinement the tag moves by less than the mesh. So the sums form a Cauchy sequence and converge. The one analytic input is that a continuous function on a compact interval does not merely move a little near each point but moves a little **uniformly**, which is compactness.

Proof.

Claim. For every $\varepsilon > 0$ there is $\delta > 0$ such that $\|\mathbf{M}(s) - \mathbf{M}(s')\|_F \le \varepsilon$ whenever $s, s' \in [a, b]$ and $|s - s'| < \delta$.

Proof. Suppose not. Then for some $\varepsilon > 0$ and every $k \ge 1$ the value $\delta = 1/k$ fails, so there are $s_k, s_k' \in [a, b]$ with $|s_k - s_k'| < 1/k$ and $\|\mathbf{M}(s_k) - \mathbf{M}(s_k')\|_F > \varepsilon$. The interval $[a, b]$ is a closed bounded subset of $\mathbb{R}$, so by the compactness of closed bounded sets, **fact (A3) of Chapter 15's introduction**, a subsequence s_{k_j} converges to some $s \in [a, b]$. Then $s_{k_j}' \to s$ as well, since $|s_{k_j}' - s| \le |s_{k_j}' - s_{k_j}| + |s_{k_j} - s| \to 0$. Continuity of $\mathbf{M}$ gives $\mathbf{M}(s_{k_j}) \to \mathbf{M}(s)$ and $\mathbf{M}(s_{k_j}') \to \mathbf{M}(s)$, so $\|\mathbf{M}(s_{k_j}) - \mathbf{M}(s_{k_j}')\|_F \to 0$, contradicting the lower bound ε. ∎

Fix $\varepsilon > 0$ and let δ be as in the claim. Let P be a tagged partition of mesh $< \delta$, and let Q be a tagged partition whose division points include those of P. Each interval q of Q lies inside exactly one interval of P; write $\tau(q)$ for the tag of that interval of P and $\rho(q)$ for the tag of q. Splitting each term of $S(\mathbf{M}, P)$ along the intervals of Q inside it,

$$S(\mathbf{M}, P) - S(\mathbf{M}, Q) = \sum_{q} \big(\mathbf{M}(\tau(q)) - \mathbf{M}(\rho(q))\big)|q|,$$

where $|q|$ is the length of q. Both $\tau(q)$ and $\rho(q)$ lie in one interval of P, of length $< \delta$, so each bracket has Frobenius norm at most ε. The triangle inequality gives

$$\|S(\mathbf{M}, P) - S(\mathbf{M}, Q)\|_F \;\le\; \varepsilon \sum_{q} |q| \;=\; \varepsilon(b - a).$$

If P and P' both have mesh $< \delta$, take for Q the partition whose division points are those of P together with those of P', with any tags; applying the bound twice,

$$\|S(\mathbf{M}, P) - S(\mathbf{M}, P')\|_F \;\le\; 2\varepsilon(b - a). \tag{$*$}$$

Now let (P_k) be tagged partitions with meshes tending to 0. Given $\eta > 0$, apply $(*)$ with $\varepsilon = \eta/(2(b - a) + 1)$: for all k, l large enough that both meshes are $< \delta$, $\|S(\mathbf{M}, P_k) - S(\mathbf{M}, P_l)\|_F < \eta$. So each entry of $S(\mathbf{M}, P_k)$ is a Cauchy sequence of complex numbers, hence convergent by **completeness, fact (A1)**; call the entrywise limit J. If (P_k') is a second such sequence, interleaving the two produces a third sequence of meshes tending to 0, whose sums converge; both subsequences must have that common limit, so the limits agree. This proves the proposition.

∎

Definition 20.10.1 — Integral of a Continuous Matrix-Valued Function

Let $\mathbf{M}\colon [a,b] \to M_{p\times q}(\mathbb{C})$ be continuous. Its **integral**

$$\int_a^b \mathbf{M}(s)\,\mathrm{d}s \;\in\; M_{p\times q}(\mathbb{C})$$

is the matrix J of Proposition 20.10.1. For a continuous $\mathbf{M}$ on an open or half-open interval with endpoints $a < b$, where $a = -\infty$ or $b = +\infty$ is allowed, the **improper integral** $\int_a^b \mathbf{M}(s)\,\mathrm{d}s$ is the matrix J', if one exists, such that

$$\int_{\alpha_k}^{\beta_k} \mathbf{M}(s)\,\mathrm{d}s \;\longrightarrow\; J' \quad \text{entrywise}$$

for every pair of sequences with $\alpha_k \to a$, $\beta_k \to b$ and $a < \alpha_k < \beta_k < b$. The integral is then said to **converge**.

Five properties are used below, and each is read off the Riemann sums together with the algebra of limits.

- **Entrywise.** The (i,j) entry of $\int_a^b \mathbf{M}$ is $\int_a^b m_{ij}$, because that is true of every Riemann sum. In particular Definition 20.10.1 for $p = q = 1$ is the ordinary Riemann integral of a continuous complex function.
- **Linear.** $\int(\mathbf{M}+\mathbf{N}) = \int \mathbf{M} + \int \mathbf{N}$ and $\int c\mathbf{M} = c\int \mathbf{M}$ for a scalar c.
- **Additive in the interval.** For $a < c < b$, $\int_a^b \mathbf{M} = \int_a^c \mathbf{M} + \int_c^b \mathbf{M}$: joining a tagged partition of $[a,c]$ to one of $[c,b]$ gives a tagged partition of $[a,b]$ whose Riemann sum is the sum of the two, and the meshes tend to 0 together.
- **Constant factors pass out.** For constant $\mathbf{X} \in M_{r\times p}(\mathbb{C})$ and $\mathbf{Y} \in M_{q\times r'}(\mathbb{C})$, $\int_a^b \mathbf{X}\mathbf{M}(s)\mathbf{Y}\,\mathrm{d}s = \mathbf{X}\big(\int_a^b \mathbf{M}\big)\mathbf{Y}$, since $S(\mathbf{X}\mathbf{M}\mathbf{Y}, P) = \mathbf{X}\,S(\mathbf{M}, P)\,\mathbf{Y}$.
- **Pairing passes in.** Taking $\mathbf{X} = \mathbf{x}^*$ and $\mathbf{Y} = \mathbf{x}$ in the previous item, $\mathbf{x}^*\big(\int_a^b \mathbf{M}\big)\mathbf{x} = \int_a^b \mathbf{x}^*\mathbf{M}(s)\mathbf{x}\,\mathrm{d}s$.

All five hold for a convergent improper integral, by taking the limit in α and β.

Now the lemma the whole section is for.

Lemma 20.10.2 — The Integral of a Positive Semidefinite Integrand

Let $\mathbf{M}\colon [a,b] \to M_n(\mathbb{C})$ be continuous with $\mathbf{M}(s) \succeq 0$ for every $s \in [a,b]$. Then

$$\int_a^b \mathbf{M}(s)\,\mathrm{d}s \;\succeq\; 0.$$

The same conclusion holds for a **convergent improper** integral of a continuous integrand that is $\succeq 0$ at every point of the interval.

Proof. Let $\mathbf{x} \in \mathbb{C}^n$. For a tagged partition P,

$$\mathbf{x}^* S(\mathbf{M}, P)\mathbf{x} = \sum_{i=1}^{N} \big(\mathbf{x}^* \mathbf{M}(\tau_i)\mathbf{x}\big)(s_i - s_{i-1}),$$

a sum of products of two non-negative real numbers, since $\mathbf{M}(\tau_i) \succeq 0$ (Definition 12.1.1) and the interval lengths are positive. Hence $\mathbf{x}^* S(\mathbf{M}, P)\mathbf{x} \geq 0$ for every P. Taking any sequence of tagged partitions with meshes tending to 0 and using Proposition 20.10.1, $\mathbf{x}^* S(\mathbf{M}, P_k)\mathbf{x} \to \mathbf{x}^* \big(\int_a^b \mathbf{M}\big)\mathbf{x}$; a non-strict inequality survives a limit, so that number is ≥ 0.

It remains to check that $\int_a^b \mathbf{M}$ is Hermitian. Each $\mathbf{M}(s)$ is Hermitian, so each Riemann sum is, and the entrywise limit of Hermitian matrices is Hermitian: $\overline{(\int m_{ji})} = \int \overline{m_{ji}} = \int m_{ij}$, since conjugation is continuous and commutes with sums. So $\int_a^b \mathbf{M} \succeq 0$.

For the improper case, each proper integral $\int_\alpha^\beta \mathbf{M}$ is $\succeq 0$ by what has just been proved, and $\mathbf{x}^* \big(\int_a^b \mathbf{M}\big)\mathbf{x}$ is the limit of the numbers $\mathbf{x}^* \big(\int_\alpha^\beta \mathbf{M}\big)\mathbf{x} \geq 0$, and the limit is Hermitian for the same reason.

■

That is the whole of the promised analysis. Nothing in it is deep: the positive semidefinite matrices are closed under sums and under multiplication by non-negative numbers, and they are closed under limits, so a limit of sums of them stays inside.

Quick check. Let $\mathbf{M}(t) = \left(\begin{smallmatrix} 1 & t \\ t & t^2 \end{smallmatrix}\right)$ for $t \in [0,1]$. Is $\mathbf{M}(t) \succeq 0$ for each t? Compute $\int_0^1 \mathbf{M}(t)\,\mathrm{d}t$ and check that the answer is $\succeq 0$. Does it have rank 1?

Solution. For each t, $\mathbf{M}(t) = \mathbf{v}(t)\mathbf{v}(t)^\top$ with $\mathbf{v}(t) = (1, t)$, so $\mathbf{x}^\top \mathbf{M}(t)\mathbf{x} = (x_1 + t x_2)^2 \geq 0$ and $\mathbf{M}(t) \succeq 0$. Integrating entrywise, and using $\int_0^1 t\,\mathrm{d}t = \frac{1}{2}$ and $\int_0^1 t^2\,\mathrm{d}t = \frac{1}{3}$ (for a continuous integrand these can be read off the Riemann sums $N^{-2}\sum_{i \leq N} i$ and $N^{-3}\sum_{i \leq N} i^2$),

$$\int_0^1 \mathbf{M}(t)\,\mathrm{d}t = \begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix},$$

whose determinant is $\frac{1}{3} - \frac{1}{4} = \frac{1}{12} > 0$ and whose $(1,1)$ entry is positive, so it is positive definite by Sylvester's criterion (Theorem 12.1.5 (d)). It has rank 2, not 1: every integrand was a rank-one matrix, and the integral is not. Lemma 20.10.2 preserves positivity and nothing else.

20.10.2 The one fact this chapter quotes

Two statements in this chapter are not proved from Chapters 1–19: the one below, and Lieb's concavity theorem, which §12 states and nothing in the book uses. Beside them this section quotes two standard facts of one-variable calculus, the fundamental theorem of calculus and the substitution rule, each named at the point where it is used. The book's practice for such a fact is fixed — Chapter 10 with the theorem of Abel and Ruffini, Chapter 13 §06 with Taylor's theorem — and it is followed here: the statement is given in full, in a block of its own, named at every use, and never buried inside a proof that presents itself as self-contained.

Theorem 20.10.3 — (A7) The Theorem of Pick and Nevanlinna

Let $I \subseteq \mathbb{R}$ be an open interval and let $f\colon I \to \mathbb{R}$.

(a) Suppose that f is differentiable and that for every $n \geq 1$ and all $t_1, \dots, t_n \in I$ the Loewner matrix $L_f(t_1, \dots, t_n)$ of Definition 20.9.2 is positive semidefinite. Then f is the restriction to I of a function analytic on $\mathbb{C} \setminus (\mathbb{R} \setminus I)$ that maps every point of the upper half-plane $\{z : \operatorname{Im} z > 0\}$ to a point with non-negative imaginary part.

(b) Conversely, every function analytic on $\mathbb{C} \setminus (-\infty, 0]$ that maps the upper half-plane into $\{\operatorname{Im} z \geq 0\}$ has, on $I = (0, \infty)$, the integral representation of Theorem 16.11.9 (ii): there are $\alpha \in \mathbb{R}$, $\beta \geq 0$ and a positive measure ν on $[0, \infty)$ with $\int (1 + s^2)^{-1} \mathrm{d}\nu(s) < \infty$ such that

$$f(t) = \alpha + \beta t + \int_{[0,\infty)} \Big(\frac{s}{1+s^2} - \frac{1}{t+s} \Big) \mathrm{d}\nu(s)$$

for every $t > 0$.

(c) A function that is operator monotone on an open interval is continuously differentiable there.

What it gives. Exactly one thing: it converts an infinite family of matrix conditions — one positive semidefinite Loewner matrix for each size and each choice of points — into a single formula with two constants and one measure. Nothing in the statement is about matrices at all after clause (a) is applied.

What it costs. Clause (a) is complex analysis: one shows that the positivity of the Loewner matrices forces f to extend analytically across I, and that the extension preserves the upper half-plane. Clause (b) is the Herglotz–Riesz representation of such a function, which produces the measure ν by a compactness argument in a space of measures. Clause (c) is a regularity theorem. None of these is within reach of Chapters 1–19, and Chapter 16 §11 said so when it stated the theorem: "Its proof needs complex analysis and some measure theory, which lie outside Chapter 15's list (A1)–(A6)."

A second cost, worth naming separately. The integral in (b) is taken against a measure, and this book constructs no such integral. Definition 20.10.1 covers the case $\mathrm{d}\nu(s) = w(s)\,\mathrm{d}s$ with w continuous, and that is the only case the corollaries below need: each of them starts from a representation written down and verified by hand, with a continuous density. For a general ν, which is what (b) allows, the argument uses exactly two properties of the integral: it is **linear** in the integrand, and it sends a **non-negative** integrand to a non-negative number. Both are part of the meaning of "integral against a positive measure". For the integral the book does construct they are proved — linearity in the list of properties after Definition 20.10.1, positivity in Lemma 20.10.2; for a general measure they are quoted, along with (A7) itself.

Which half rests on it. Only the hard half. In Theorem 20.10.4 below, the implication (ii) ⇒ (i) is proved here from Chapter 16 §11 and Lemma 20.10.2, with no appeal to (A7) — subject only to the second cost just named, since for a general ν the linearity and the positivity of the integral are quoted rather than constructed. The implications (i) ⇒ (iii) ⇒ (ii) — the classification itself — use (A7) and cannot be had without it. Nothing else in this chapter uses (A7); in particular Corollary 20.10.8, Corollary 20.10.9 and Corollary 20.10.10 below, which are what the earlier chapters actually asked for, are proved without it.

20.10.3 Loewner's theorem

Theorem 20.10.4 — Loewner's Theorem

Let $f\colon (0,\infty)\to\mathbb{R}$. The following are equivalent.

(i) f is operator monotone on $(0,\infty)$.

(ii) There are $\alpha\in\mathbb{R}$, $\beta\geq 0$ and a positive measure ν on $[0,\infty)$ with $\int(1+s^2)^{-1}\mathrm{d}\nu(s)<\infty$ such that for every $t>0$

$$f(t)=\alpha+\beta t+\int_{[0,\infty)}\Big(\frac{s}{1+s^2}-\frac{1}{t+s}\Big)\mathrm{d}\nu(s).$$

(iii) f is the restriction to $(0,\infty)$ of a function analytic on $\mathbb{C}\setminus(-\infty,0]$ that sends every point of the upper half-plane to a point with non-negative imaginary part.

These are the three conditions of Theorem 16.11.9.

Idea. Three steps, in a cycle.

① (ii) ⇒ (i). At each fixed $s\geq 0$ the integrand is $-1/(t+s)$ plus a constant, and Corollary 16.11.5 already knows those are operator monotone. Subtracting $f(\mathbf{B})$ from $f(\mathbf{A})$ kills the constants and leaves an integral of positive semidefinite matrices, which Lemma 20.10.2 declares positive semidefinite.

② (i) ⇒ (iii). Operator monotonicity is monotonicity of every order, and §09 converts that into positivity of every Loewner matrix. (A7) converts that into analyticity.

③ (iii) ⇒ (ii). (A7) again.

Proof. **Step 1: (ii) ⇒ (i).** Let $\mathbf{A},\mathbf{B}\in M_n(F)$ be Hermitian with spectra in $(0,\infty)$ and $\mathbf{A}\succeq\mathbf{B}$. For $s\geq 0$ put $g_s(t)=-1/(t+s)$ on $(0,\infty)$. By Corollary 16.11.5, g_s is operator monotone there, so

$$\mathbf{R}(s)\coloneqq g_s(\mathbf{A})-g_s(\mathbf{B})=(\mathbf{B}+s\mathbf{I})^{-1}-(\mathbf{A}+s\mathbf{I})^{-1}$$

satisfies $\mathbf{R}(s)\succeq 0$ for every $s\geq 0$; the identification of $g_s(\mathbf{A})$ with $-(\mathbf{A}+s\mathbf{I})^{-1}$ is Definition 11.8.2 applied to the spectral resolution of $\mathbf{A}$.

Write $\mathbf{A}=\sum_j\mu_j\mathbf{P}_j$ for that resolution (Theorem 11.8.1). By Definition 11.8.2 and the hypothesis (ii),

$$\begin{aligned}f(\mathbf{A})&=\sum_j f(\mu_j)\mathbf{P}_j\\&=\alpha\mathbf{I}+\beta\mathbf{A}\\&\quad+\int_{[0,\infty)}\Big(\frac{s}{1+s^2}\mathbf{I}-(\mathbf{A}+s\mathbf{I})^{-1}\Big)\mathrm{d}\nu(s),\end{aligned}$$

where the second line substitutes the formula (ii) for each $f(\mu_j)$ and moves the finite sum $\sum_j(\cdot)\mathbf{P}_j$ inside the integral, which is legitimate because the integral is **linear** in its integrand and the $\mathbf{P}_j$ do not depend on s; the identities $\sum_j\mathbf{P}_j=\mathbf{I}$ and $\sum_j\mu_j\mathbf{P}_j=\mathbf{A}$ are Theorem 11.8.1 (c) and (d). The same computation applies to $\mathbf{B}$. Subtracting, the

terms $\alpha\mathbf{I}$ and $\frac{s}{1+s^2}\mathbf{I}$ cancel, and

$$f(\mathbf{A}) - f(\mathbf{B}) = \beta(\mathbf{A}-\mathbf{B}) + \int_{[0,\infty)} \mathbf{R}(s)\,\mathrm{d}\nu(s).$$

Let $\mathbf{x} \in F^n$. Pairing passes inside the integral, so

$$\mathbf{x}^*\big(f(\mathbf{A}) - f(\mathbf{B})\big)\mathbf{x} = \beta\,\mathbf{x}^*(\mathbf{A}-\mathbf{B})\mathbf{x} + \int_{[0,\infty)} \mathbf{x}^*\mathbf{R}(s)\mathbf{x}\,\mathrm{d}\nu(s) \;\geq\; 0,$$

because $\beta \geq 0$, $\mathbf{x}^*(\mathbf{A}-\mathbf{B})\mathbf{x} \geq 0$, and the integrand $\mathbf{x}^*\mathbf{R}(s)\mathbf{x}$ is non-negative for every s. This last step is Lemma 20.10.2 when $\mathrm{d}\nu(s) = w(s)\mathrm{d}s$ with w continuous, and in general uses only the linearity and positivity of the integral against a positive measure, as recorded with Theorem 20.10.3. Hence $f(\mathbf{A}) \succeq f(\mathbf{B})$. The size n was arbitrary, so f is operator monotone (Definition 16.11.1 (a)).

Step 2: (i) ⇒ (iii). Let f be operator monotone on $(0,\infty)$. By Theorem 20.10.3 (c), f is continuously differentiable there. Fix $n \geq 1$ and $t_1, \dots, t_n \in (0,\infty)$. Being operator monotone, f is in particular monotone of order n, so Theorem 20.9.5 gives $L_f(t_1,\dots,t_n) \succeq 0$. As n and the points were arbitrary, the hypothesis of Theorem 20.10.3 (a) holds with $I = (0,\infty)$. Since $\mathbb{R} \setminus (0,\infty) = (-\infty, 0]$, that clause produces an analytic function on $\mathbb{C}\setminus(-\infty,0]$ restricting to f and mapping the upper half-plane into its closure. That is (iii).

Step 3: (iii) ⇒ (ii). This is Theorem 20.10.3 (b).

The cycle (i) ⇒ (iii) ⇒ (ii) ⇒ (i) closes, so the three conditions are equivalent.

■

Step 1 is the step Chapter 16 §11 identified as missing, and it turned out to cost one lemma. Steps 2 and 3 are where the content is, and they are quoted. It is worth being precise about the division: **the book proves that every function of the form (ii) is operator monotone, and quotes that there are no others.**

Warning. **Analytic and increasing is not enough.** Condition (iii) is not "extends analytically"; it is "extends analytically **and keeps the upper half-plane**". The function e^t extends to an entire function and is increasing on $\mathbb{R}$, yet $\operatorname{Im} e^z = e^x \sin y$ for $z = x + iy$, which is negative at $z = 3\pi i/2$, where $e^z = -i$. So e^t fails (iii), and Example (The exponential is not operator monotone) below confirms the failure directly with two 2×2 matrices.

20.10.4 The powers

Chapter 12 §05 announced the answer and deferred the proof:

> The dividing line is at $s = 1$: the functions preserving the order are called **operator monotone**, and $t \mapsto t^s$ is operator monotone on $[0,\infty)$ exactly for $0 \leq s \leq 1$. Chapter 20 proves this, along with the companion fact that $t \mapsto \log t$ is operator monotone while $t \mapsto e^t$ is not.

Chapter 16 §11 repeated it, adding that "the operator monotonicity of t^p for every $p \in (0,1)$ needs a new idea, an integral representation of the kind in Theorem 16.11.9". Here is the representation, and it is elementary. Real powers $t^r = e^{r \log t}$ are Chapter 17 §11's (Lemma 17.11.1).

Lemma 20.10.5 — The Integral That Represents a Power

Let $0 < p < 1$. Then the improper integral

$$K_p := \int_0^\infty \frac{u^{p-1}}{1+u}\,\mathrm{d}u$$

converges, with $0 < K_p < \infty$, and for every $\lambda > 0$

$$\int_0^\infty s^{p-1}\,\frac{\lambda}{\lambda+s}\,\mathrm{d}s \;=\; K_p\,\lambda^p.$$

Idea. Both halves are one idea. For convergence, cut $(0,\infty)$ at the powers of 2: on each piece the integrand is bounded by its value at one endpoint, and the resulting bounds form a geometric series, convergent exactly because $0 < p < 1$. For the identity, substitute $s = \lambda u$; since the substitution is linear it can be made inside the Riemann sums, where it is visible as a relabeling of the partition together with a factor λ^p.

Proof. **Convergence.** The integrand is positive and continuous on $(0,\infty)$, so interval additivity makes $\delta \mapsto \int_\delta^1$ increase as δ decreases and $R \mapsto \int_1^R$ increase with R; the same property splits each range at the powers of 2 below. It is enough to bound both families above: bounded above, they have a least upper bound L by **completeness, fact (A1) of Chapter 15's introduction**, and monotonicity in the parameter makes L the limit along *every* sequence of parameters tending to the endpoint, which is the form Definition 20.10.1 asks for; along a decreasing sequence $\delta_k \to 0^+$ that limit is **monotone convergence, fact (A2)**. Since $p-1<0$, the function u^{p-1} is decreasing, so on $[2^{-k-1}, 2^{-k}]$ it is at most $(2^{-k-1})^{p-1} = 2^{(k+1)(1-p)}$; as $1/(1+u) \le 1$ and the interval has length 2^{-k-1}, the integral over it is at most $2^{-(k+1)p}$. Summing the geometric series,

$$\int_\delta^1 \frac{u^{p-1}}{1+u}\,\mathrm{d}u \;\le\; \sum_{k\ge 0} 2^{-(k+1)p} = \frac{1}{2^p-1},$$

for every $\delta \in (0,1)$. For the other end use $u^{p-1}/(1+u) \le u^{p-2}$, which on $[2^k, 2^{k+1}]$ is at most $2^{k(p-2)}$; the interval has length 2^k, so the integral over it is at most $2^{k(p-1)}$, and

$$\int_1^R \frac{u^{p-1}}{1+u}\,\mathrm{d}u \;\le\; \sum_{k\ge 0} 2^{k(p-1)} = \frac{1}{1-2^{p-1}},$$

which is finite because $p-1<0$. So $K_p < \infty$, and $K_p > 0$ because the integrand is positive and $\int_1^2$ is already positive.

The identity. Fix $\lambda > 0$ and $0 < \delta < R$. Let P be a tagged partition $\delta/\lambda = u_0 < \cdots < u_N = R/\lambda$ with tags v_i. Multiplying every point by λ gives a tagged partition λP of $[\delta, R]$, with tags λv_i and mesh λ times that of P. Writing $g(s) = s^{p-1}\lambda/(\lambda+s)$ and

$h(u) = u^{p-1}/(1+u)$,

$$g(\lambda v_i)\cdot\lambda(u_i-u_{i-1}) = \frac{\lambda^{p-1}v_i^{p-1}\lambda}{\lambda(1+v_i)}\,\lambda(u_i-u_{i-1}) = \lambda^p\,h(v_i)(u_i-u_{i-1}),$$

using $(\lambda v)^{p-1} = \lambda^{p-1}v^{p-1}$ (Lemma 17.11.1 and the rules for real powers recorded after it). Summing over i, $S(g,\lambda P) = \lambda^p S(h,P)$. Letting the mesh of P tend to 0 — which sends that of λP to 0 as well — and using Proposition 20.10.1 on both sides,

$$\int_\delta^R g(s)\,\mathrm{d}s = \lambda^p\int_{\delta/\lambda}^{R/\lambda} h(u)\,\mathrm{d}u.$$

Now let $\delta\to 0^+$ and $R\to\infty$. The right side tends to $\lambda^p K_p$ by the first part, so the left side converges to it. This proves the lemma.

■

Remark. The number K_p equals $\pi/\sin(p\pi)$. That evaluation is a standard exercise in contour integration, and the constant $\sin(p\pi)/\pi$ is the one Chapter 16 §11 displayed. Nothing below needs its value: only $0<K_p<\infty$ is used, and that was proved. Exercise B2 computes $K_{1/2}=\pi$ by hand.

Two more small tools, both elementary, and then the corollary.

Lemma 20.10.6 — Composites of Operator Monotone Functions

Let I, J be intervals, let $g\colon I\to\mathbb{R}$ be operator monotone on I with $g(I)\subseteq J$, and let $h\colon J\to\mathbb{R}$ be operator monotone on J. Then $h\circ g$ is operator monotone on I.

Proof. Let $\mathbf{A},\mathbf{B}\in M_n(F)$ be Hermitian with spectra in I and $\mathbf{A}\succeq\mathbf{B}$. Then $g(\mathbf{A})\succeq g(\mathbf{B})$, and both are Hermitian (Theorem 11.8.3 (c)) with spectra $g(\operatorname{spec}(\mathbf{A}))$ and $g(\operatorname{spec}(\mathbf{B}))$ by Theorem 11.8.3 (d), hence contained in $g(I)\subseteq J$. So $h(g(\mathbf{A}))\succeq h(g(\mathbf{B}))$.

It remains to see that $h(g(\mathbf{A})) = (h\circ g)(\mathbf{A})$. Let $\mathbf{A}=\sum_j \mu_j\mathbf{P}_j$ be the spectral resolution. Group the indices by the value of g: let $\nu_1,\dots,\nu_r$ be the distinct numbers among $g(\mu_1),\dots,g(\mu_k)$ and put $\mathbf{Q}_l=\sum_{j:g(\mu_j)=\nu_l}\mathbf{P}_j$. Each $\mathbf{Q}_l$ is a non-zero orthogonal projection, $\mathbf{Q}_l\mathbf{Q}_{l'}=\mathbf{0}$ for $l\neq l'$, and $\sum_l\mathbf{Q}_l=\mathbf{I}$, by Theorem 11.8.1 (b) and (c). Since $g(\mathbf{A})=\sum_l\nu_l\mathbf{Q}_l$ with the ν_l distinct, Theorem 11.8.2 says this is the spectral resolution of $g(\mathbf{A})$. Hence, by Definition 11.8.2 applied twice,

$$h(g(\mathbf{A})) = \sum_l h(\nu_l)\mathbf{Q}_l = \sum_j h(g(\mu_j))\mathbf{P}_j = (h\circ g)(\mathbf{A}).$$

The same holds for $\mathbf{B}$, so $(h\circ g)(\mathbf{A})\succeq(h\circ g)(\mathbf{B})$.

■

Lemma 20.10.7 — Pointwise Limits Stay Operator Monotone

Let $f_k\colon I \to \mathbb{R}$ be operator monotone on I for every k, and suppose $f_k(t) \to f(t)$ for every $t \in I$. Then f is operator monotone on I.

Proof. Let $\mathbf{A} \succeq \mathbf{B}$ be Hermitian of the same size with spectra in I, with spectral resolutions $\mathbf{A} = \sum_j \mu_j \mathbf{P}_j$ and $\mathbf{B} = \sum_l \nu_l \mathbf{Q}_l$. By Definition 11.8.2, $f_k(\mathbf{A}) = \sum_j f_k(\mu_j)\mathbf{P}_j$, a fixed finite combination of fixed matrices with scalar coefficients converging to $f(\mu_j)$; so $f_k(\mathbf{A}) \to f(\mathbf{A})$ entrywise, and likewise $f_k(\mathbf{B}) \to f(\mathbf{B})$. For each $\mathbf{x}$ and each k, $\mathbf{x}^*(f_k(\mathbf{A}) - f_k(\mathbf{B}))\mathbf{x} \geq 0$, and the left side tends to $\mathbf{x}^*(f(\mathbf{A}) - f(\mathbf{B}))\mathbf{x}$. A non-strict inequality survives a limit, so $f(\mathbf{A}) \succeq f(\mathbf{B})$.

■

Corollary 20.10.8 — The Operator Monotone Powers

Let $p \in \mathbb{R}$. The function $t \mapsto t^p$ is operator monotone on $(0, \infty)$ **if and only if** $0 \leq p \leq 1$. For those p the statement extends to $[0, \infty)$: if $\mathbf{A} \succeq \mathbf{B} \succeq 0$ are Hermitian of the same size, then $\mathbf{A}^p \succeq \mathbf{B}^p$.

Idea. For $0 < p < 1$, Lemma 20.10.5 rewrites t^p as a positive superposition of the functions $t/(t+s)$ that Chapter 16 §11 already proved operator monotone, and the superposition is an honest Riemann integral, so Lemma 20.10.2 finishes it. For $p > 1$ the trick is that operator monotone functions compose: if t^p were operator monotone for one $p > 1$, enough compositions with each other and with a small power would manufacture t^2, which is not.

Proof. **The cases $p = 0$ and $p = 1$.** These are the constant 1 and the identity, operator monotone by Proposition 16.11.2.

The case $p < 0$. Then $t \mapsto t^p$ is strictly decreasing on $(0, \infty)$, since $t \mapsto t^{-p}$ is strictly increasing there (Chapter 17 §11). An operator monotone function is increasing (Proposition 16.11.1), so it is not operator monotone.

The case $0 < p < 1$, on $(0, \infty)$. Let $\mathbf{A} \succeq \mathbf{B}$ be Hermitian in $M_n(F)$ with spectra in $(0, \infty)$. Write $\mathbf{A} = \mathbf{U}\mathbf{D}\mathbf{U}^*$ with $\mathbf{U}$ unitary and $\mathbf{D} = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$ the eigenvalues, all positive (Corollary 11.4.3, Corollary 11.5.2, Theorem 12.1.5 (b)). For $s > 0$,

$$s^{p-1}\mathbf{A}(\mathbf{A} + s\mathbf{I})^{-1} = \mathbf{U}\operatorname{diag}\Big(\frac{s^{p-1}\lambda_i}{\lambda_i + s}\Big)\mathbf{U}^*,$$

where we are using that $f(\mathbf{A}) = \mathbf{U}\operatorname{diag}(f(\lambda_1), \dots, f(\lambda_n))\mathbf{U}^*$ for every function f on $\operatorname{spec}(\mathbf{A})$: writing $\mathbf{u}_1, \dots, \mathbf{u}_n$ for the columns of $\mathbf{U}$, the spectral projection $\mathbf{P}_j$ of Definition 11.8.1 is $\sum_{i:\lambda_i = \mu_j} \mathbf{u}_i\mathbf{u}_i^*$, so the two expressions for $f(\mathbf{A})$ have the same terms. Every entry of the integrand is therefore a fixed linear combination of the n scalar functions of Lemma 20.10.5. By that lemma each of their improper integrals converges, so the matrix integral converges, and by the linearity of the integral together with the rule that constant factors pass out,

$$\int_0^\infty s^{p-1}\mathbf{A}(\mathbf{A} + s\mathbf{I})^{-1}\mathrm{d}s = K_p\,\mathbf{U}\operatorname{diag}(\lambda_i^p)\mathbf{U}^* = K_p\,\mathbf{A}^p,$$

the last equality by Definition 11.8.2. The same holds for $\mathbf{B}$. Subtracting,

$$\mathbf{A}^p - \mathbf{B}^p = \frac{1}{K_p}\int_0^\infty s^{p-1}\big(\mathbf{C}(s) - \mathbf{Y}(s)\big)\,\mathrm{d}s,$$

with $\mathbf{C}(s) = \mathbf{A}(\mathbf{A}+s\mathbf{I})^{-1}$ and $\mathbf{Y}(s) = \mathbf{B}(\mathbf{B}+s\mathbf{I})^{-1}$. Fix $s > 0$. The function $t \mapsto t/(t+s)$ is operator monotone on $(0,\infty)$ by Corollary 16.11.5, and it sends $\mathbf{A}$ to $\mathbf{C}(s)$ and $\mathbf{B}$ to $\mathbf{Y}(s)$; hence $\mathbf{C}(s) - \mathbf{Y}(s) \succeq 0$, and multiplying by the positive number s^{p-1} keeps it so. The integrand is continuous in s on $(0,\infty)$ and the integral converges, so Lemma 20.10.2 in its improper form gives $\mathbf{A}^p - \mathbf{B}^p \succeq 0$. As $K_p > 0$ and n was arbitrary, $t \mapsto t^p$ is operator monotone on $(0,\infty)$.

The case $p > 1$. Suppose, for a contradiction, that $t \mapsto t^p$ is operator monotone on $(0,\infty)$ for some $p > 1$. It maps $(0,\infty)$ into itself, so by Lemma 20.10.6 it may be composed with itself: $t \mapsto t^{p^k}$ is operator monotone for every $k \geq 1$. Choose k with $p^k \geq 2$ and put $q = 2/p^k \in (0,1]$. By the cases already proved, $t \mapsto t^q$ is operator monotone on $(0,\infty)$ and maps it into itself, so Lemma 20.10.6 applied to $g(t) = t^q$ and $h(u) = u^{p^k}$ makes

$$t \longmapsto (t^q)^{p^k} = t^{\,qp^k} = t^2$$

operator monotone on $(0,\infty)$.

Now let $\mathbf{A} \succeq \mathbf{B} \succeq 0$ be Hermitian and let $\varepsilon > 0$. Then $\mathbf{A} + \varepsilon\mathbf{I} \succeq \mathbf{B} + \varepsilon\mathbf{I} \succ 0$, both with spectra in $(0,\infty)$, so $(\mathbf{A}+\varepsilon\mathbf{I})^2 \succeq (\mathbf{B}+\varepsilon\mathbf{I})^2$. Expanding both squares, that says

$$\mathbf{A}^2 - \mathbf{B}^2 + 2\varepsilon(\mathbf{A} - \mathbf{B}) \;\succeq\; 0.$$

Fix $\mathbf{x}$ and let $\varepsilon \to 0^+$: the number $\mathbf{x}^*(\mathbf{A}^2 - \mathbf{B}^2)\mathbf{x} + 2\varepsilon\,\mathbf{x}^*(\mathbf{A}-\mathbf{B})\mathbf{x}$ is ≥ 0 for every $\varepsilon > 0$, so its limit $\mathbf{x}^*(\mathbf{A}^2 - \mathbf{B}^2)\mathbf{x}$ is ≥ 0. Hence $\mathbf{A}^2 \succeq \mathbf{B}^2$ whenever $\mathbf{A} \succeq \mathbf{B} \succeq 0$, contradicting Example (Squaring does not preserve the Loewner order). So no $p > 1$ works.

Extension to $[0,\infty)$ for $0 \leq p \leq 1$. Let $\mathbf{A} \succeq \mathbf{B} \succeq 0$ and $\varepsilon > 0$. As above $\mathbf{A} + \varepsilon\mathbf{I} \succeq \mathbf{B} + \varepsilon\mathbf{I} \succ 0$, so $(\mathbf{A}+\varepsilon\mathbf{I})^p \succeq (\mathbf{B}+\varepsilon\mathbf{I})^p$. If $\mathbf{A} = \sum_j \mu_j \mathbf{P}_j$ is the spectral resolution, then $\mathbf{A} + \varepsilon\mathbf{I} = \sum_j (\mu_j + \varepsilon)\mathbf{P}_j$ is the spectral resolution of $\mathbf{A} + \varepsilon\mathbf{I}$ (Theorem 11.8.2, as the shifted eigenvalues are still distinct), so

$$(\mathbf{A}+\varepsilon\mathbf{I})^p = \sum_j (\mu_j + \varepsilon)^p \mathbf{P}_j \;\longrightarrow\; \sum_j \mu_j^p \mathbf{P}_j = \mathbf{A}^p$$

as $\varepsilon \to 0^+$: for $\mu_j > 0$ this is the continuity of $u \mapsto e^{p\log u}$ on $(0,\infty)$ (Lemma 17.11.1), and for $\mu_j = 0$ it says $\varepsilon^p \to 0$, which holds because $u \mapsto u^p$ is a strictly increasing bijection of $[0,\infty)$ with itself, so $\varepsilon^p < \eta$ as soon as $\varepsilon < \eta^{1/p}$. The same for $\mathbf{B}$. Pairing with $\mathbf{x}$ and letting $\varepsilon \to 0^+$ gives $\mathbf{x}^*(\mathbf{A}^p - \mathbf{B}^p)\mathbf{x} \geq 0$. This proves the corollary.

■

This pays Chapter 12 §05 and Chapter 16 §11 in full for the powers, and it is worth recording what it cost: Corollary 16.11.5 from Chapter 16 §11, Lemma 20.10.2 from the first part of this section, and facts (A1)–(A3). **Neither the theorem of Pick and Nevanlinna nor Theorem 20.10.4 itself was used** — Chapter 16 §11 expected the powers to arrive with Loewner's theorem, and they arrived without it. What (A7) adds is the knowledge that the representation exists for *every* operator monotone function; for the particular function t^p the representation was written down and verified by hand.

Quick check. In Theorem 20.10.4 (ii), why does the term $s/(1+s^2)$ inside the integral play no part in the proof that f is operator monotone?

Solution. Because it does not depend on t. Applying the functional calculus turns it into $\big(s/(1+s^2)\big)\mathbf{I}$, the same matrix for $\mathbf{A}$ as for $\mathbf{B}$, so it cancels in $f(\mathbf{A})-f(\mathbf{B})$. Its only job is to make the integral converge: without it the integrand $-1/(t+s)$ alone need not be integrable at $s=\infty$ against ν, while the difference $s/(1+s^2)-1/(t+s)$ decays like s^{-2}.

20.10.5 The logarithm and the exponential

Corollary 20.10.9 — The Logarithm Is Operator Monotone

The function $t \mapsto \log t$ is operator monotone on $(0,\infty)$.

Idea. The logarithm is a limit of powers: $(t^p-1)/p \to \log t$ as $p \to 0^+$, because that quotient is a difference quotient for the exponential. Each $(t^p-1)/p$ is an increasing affine function of an operator monotone function, and Lemma 20.10.7 passes to the limit.

Proof. For $0<p<1$ put $f_p(t)=(t^p-1)/p$ on $(0,\infty)$. By Corollary 20.10.8, $t \mapsto t^p$ is operator monotone there, and $f_p = -\frac{1}{p} + \frac{1}{p}\,t^p$ with $1/p>0$, so f_p is operator monotone by Proposition 16.11.4 (a).

Fix $t>0$. If $t=1$ then $f_p(1)=0=\log 1$ for every p. If $t\neq 1$, write $c=\log t \neq 0$ and $x=pc$, so that $t^p = e^{pc} = e^x$ by the definition of real powers (Chapter 17 §11) and

$$f_p(t) = \frac{e^x-1}{p} = c\,\frac{e^x-1}{x}.$$

As $p \to 0^+$ we have $x \to 0$, and $(e^x-1)/x \to 1$, this being the difference quotient of exp at 0, whose value is $e^0=1$ (Theorem 9.9.4 (b) in size 1, as recorded in the proof of Lemma 17.11.1). Hence $f_p(t) \to c = \log t$.

Taking $p=1/k$ and letting $k \to \infty$, Lemma 20.10.7 applies and log is operator monotone on $(0,\infty)$.

■

Remark. The logarithm's place in Theorem 20.10.4 (ii) is as simple as it can be: $\alpha=0$, $\beta=0$ and ν the ordinary length measure, so that

$$\log t = \int_0^\infty \Big(\frac{s}{1+s^2} - \frac{1}{t+s}\Big)\,\mathrm{d}s$$

for every $t>0$. To verify this, take $0<\delta<R$ and use the fundamental theorem of calculus — an imported fact of one-variable calculus, quoted here and named again in the one proof that uses this representation, Corollary 20.10.10 — with the antiderivative $\frac{1}{2}\log(1+s^2) - \log(t+s)$, whose derivative is the integrand. The value at R is $\log\big(\sqrt{1+R^2}/(t+R)\big) \to 0$, and the value at δ is $\log\big(\sqrt{1+\delta^2}/(t+\delta)\big) \to \log(1/t) = -\log t$. The difference is $\log t$.

That representation has one more use, and it pays a debt of §08. The list of operator convex functions there stopped short of two, $-\log t$ and $t\log t$, because each needs an integral representation. The display above is that representation, and it settles both at once.

Corollary 20.10.10 — Two Operator Convex Functions from the Logarithm

The functions $t \mapsto -\log t$ and $t \mapsto t\log t$ are operator convex on $(0,\infty)$.

Idea. Read the representation of $\log t$ for a fixed s instead of for a fixed t. The integrand of $-\log t$ is then $1/(t+s)$ plus a constant, and Theorem 20.8.3 (d) already knows that function is operator convex; multiplying the representation through by t turns the integrand into $-t/(t+s)$ plus an affine function, and the same clause knows $t/(t+s)$ is operator **concave**. Either way the convexity defect is an integral of positive semidefinite matrices, which Lemma 20.10.2 declares positive semidefinite.

Proof. Write $c(s) = s/(1+s^2)$. The representation in the remark above says that for every $t>0$

$$-\log t = \int_0^\infty \Big(\frac{1}{t+s} - c(s)\Big)\,\mathrm{d}s, \qquad t\log t = \int_0^\infty \Big(t\,c(s) - \frac{t}{t+s}\Big)\,\mathrm{d}s,$$

the second display being the first multiplied by $-t$, a constant as far as s is concerned.

Let $\mathbf{A},\mathbf{B} \in M_n(F)$ be Hermitian with spectra in $(0,\infty)$, let $\theta \in [0,1]$ and put $\mathbf{C} = \theta\mathbf{A} + (1-\theta)\mathbf{B}$, whose spectrum again lies in $(0,\infty)$, as Chapter 16 §11 checked.

The logarithm. Write $\mathbf{A} = \sum_j \mu_j \mathbf{P}_j$ for the spectral resolution (Theorem 11.8.1). Substituting the first display for each $-\log\mu_j$ and moving the finite sum $\sum_j(\cdot)\mathbf{P}_j$ inside the integral — legitimate because the integral is linear in its integrand and the $\mathbf{P}_j$ do not depend on s — gives

$$-\log\mathbf{A} = \int_0^\infty \big((\mathbf{A}+s\mathbf{I})^{-1} - c(s)\mathbf{I}\big)\,\mathrm{d}s,$$

where $\sum_j \mathbf{P}_j = \mathbf{I}$ is Theorem 11.8.1 (c) and the identification of $\sum_j(\mu_j+s)^{-1}\mathbf{P}_j$ with $(\mathbf{A}+s\mathbf{I})^{-1}$ is Definition 11.8.2, exactly as in Step 1 of Theorem 20.10.4. Every entry of the integrand is a fixed linear combination of the n convergent scalar integrals above, so the matrix integral converges. The same holds for $\mathbf{B}$ and for $\mathbf{C}$. Forming $\theta(\cdot)+(1-\theta)(\cdot)-(\cdot)$, the terms $c(s)\mathbf{I}$ cancel at each s, and the three convergent integrals combine into one:

$$\begin{aligned}&\theta(-\log\mathbf{A}) + (1-\theta)(-\log\mathbf{B}) - (-\log\mathbf{C})\\ &\quad= \int_0^\infty \big(\theta(\mathbf{A}+s\mathbf{I})^{-1} + (1-\theta)(\mathbf{B}+s\mathbf{I})^{-1} - (\mathbf{C}+s\mathbf{I})^{-1}\big)\,\mathrm{d}s.\end{aligned}$$

Fix $s>0$ and put $g_s(t) = 1/(t+s)$, so that $g_s(\mathbf{A}) = (\mathbf{A}+s\mathbf{I})^{-1}$ by Definition 11.8.2. By Theorem 20.8.3 (d), g_s is operator convex on $(0,\infty)$, so the integrand is $\theta g_s(\mathbf{A}) + (1-\theta)g_s(\mathbf{B}) - g_s(\mathbf{C}) \succeq 0$. It is continuous in s on $(0,\infty)$ and the integral converges, so Lemma 20.10.2 in its improper form makes the left side $\succeq 0$. Since n, the two matrices and θ were arbitrary, $-\log t$ is operator convex on $(0,\infty)$.

The function $t\log t$. Its functional calculus at $\mathbf{A}$ is $\mathbf{A}\log\mathbf{A}$, the product of $\mathbf{A}$ and $\log\mathbf{A}$, by Theorem 11.8.3 (b). The same substitution, now with the second display,

gives

$$\mathbf{A}\log\mathbf{A} = \int_0^\infty \big(c(s)\mathbf{A} - \mathbf{A}(\mathbf{A}+s\mathbf{I})^{-1}\big)\,\mathrm{d}s,$$

its entries again convergent, and likewise for $\mathbf{B}$ and $\mathbf{C}$. Forming the same combination, the terms $c(s)\mathbf{A}$ contribute $c(s)\big(\theta\mathbf{A}+(1-\theta)\mathbf{B}-\mathbf{C}\big)=\mathbf{0}$ at each s, so

$$\begin{aligned}&\theta\,\mathbf{A}\log\mathbf{A} + (1-\theta)\,\mathbf{B}\log\mathbf{B} - \mathbf{C}\log\mathbf{C}\\ &\quad= \int_0^\infty \big(\theta h_s(\mathbf{A}) + (1-\theta)h_s(\mathbf{B}) - h_s(\mathbf{C})\big)\,\mathrm{d}s,\end{aligned}$$

where $h_s(t) = -t/(t+s)$ and $h_s(\mathbf{A}) = -\mathbf{A}(\mathbf{A}+s\mathbf{I})^{-1}$. By Theorem 20.8.3 (d) the function $t/(t+s)$ is operator concave on $(0,\infty)$, so h_s is operator convex and each integrand is $\succeq 0$. By Lemma 20.10.2 again the left side is $\succeq 0$, and $t\log t$ is operator convex on $(0,\infty)$.

■

Both proofs quote the fundamental theorem of calculus once, through the representation of $\log t$ that the remark verified with it; nothing else outside Chapters 1–19 enters, and in particular Theorem 20.10.3 does not. With this, the two functions §08 left over are on its list.

The companion negative fact is the one Chapter 12 §05 named beside it.

Example. (The exponential is not operator monotone)

Show that $t \mapsto e^t$ is not operator monotone on $\mathbb{R}$, and exhibit two 2×2 Hermitian matrices witnessing the failure.

Solution. Order two already fails. The exponential is infinitely differentiable, so Theorem 20.9.5 applies. Take $t_1 = 1$ and $t_2 = -1$. The divided differences (Definition 20.9.1) are $f[1,1] = e$, $f[-1,-1] = e^{-1}$ and

$$f[1,-1] = \frac{e - e^{-1}}{1-(-1)} = \sinh 1,$$

so the Loewner matrix and its determinant are

$$\begin{aligned}L_{\exp}(1,-1) &= \begin{pmatrix} e & \sinh 1 \\ \sinh 1 & e^{-1}\end{pmatrix},\\ \det L_{\exp}(1,-1) &= 1 - (\sinh 1)^2.\end{aligned}$$

Subtracting the series for e^{-1} from that for e leaves only the odd terms, so $\sinh 1 = 1 + \frac{1}{3!} + \frac{1}{5!} + \cdots > 1$. The determinant is therefore negative, and $L_{\exp}(1,-1)$ is not positive semidefinite. By Theorem 20.9.5, exp is not monotone of order 2, hence not operator monotone.

An explicit pair. Take

$$\mathbf{A} = \begin{pmatrix} 2 & 1 \\ 1 & 0\end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 1 & 0 \\ 0 & -1\end{pmatrix},$$

so that $\mathbf{A}-\mathbf{B} = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 1\end{smallmatrix}\right) \succeq 0$ and $\mathbf{A} \succeq \mathbf{B}$. Write $\mathbf{A} = \mathbf{I} + \mathbf{N}$ with $\mathbf{N} = \left(\begin{smallmatrix} 1 & 1 \\ 1 & -1\end{smallmatrix}\right)$. Then $\mathbf{N}^2 = 2\mathbf{I}$, so $\mathbf{N}^{2m} = 2^m\mathbf{I}$ and $\mathbf{N}^{2m+1} = 2^m\mathbf{N}$, and summing the series of Definition 9.9.2

in two halves,

$$e^{\mathbf{N}} = (\cosh\sqrt{2})\,\mathbf{I} + \frac{\sinh\sqrt{2}}{\sqrt{2}}\,\mathbf{N}.$$

Since $\mathbf{I}$ and $\mathbf{N}$ commute, $e^{\mathbf{A}} = e \cdot e^{\mathbf{N}}$ by Theorem 9.9.4 (d), while $e^{\mathbf{B}} = \operatorname{diag}(e, e^{-1})$. Writing $c = \cosh\sqrt{2}$ and $d = (\sinh\sqrt{2})/\sqrt{2}$, a direct expansion of the 2×2 determinant, using $c^2 - 2d^2 = \cosh^2\sqrt{2} - \sinh^2\sqrt{2} = 1$, gives

$$\det\bigl(e^{\mathbf{A}} - e^{\mathbf{B}}\bigr) = e^2(1 - c + d) + (1 - c - d).$$

With $c = 2.17818\ldots$ and $d = 1.36830\ldots$ this is $-1.1417\ldots$, a negative number, so $e^{\mathbf{A}} - e^{\mathbf{B}}$ has one positive and one negative eigenvalue and $e^{\mathbf{A}} \not\succeq e^{\mathbf{B}}$.

Remark. The two halves of Chapter 12 §05's "companion fact" are now both in hand: log is operator monotone on $(0,\infty)$ (Corollary 20.10.9) and e^t is not operator monotone (Example (The exponential is not operator monotone)). Neither proof used Theorem 20.10.3. The logarithm and the exponential are inverse to each other and increasing, which shows that operator monotonicity is not inherited by inverse functions.

20.10.6 Exercises

20.10.6.1 A. Check your understanding

Exercise A1.

(a) State what Theorem 20.10.3 gives, and say which implication of Theorem 20.10.4 rests on it.

(b) Explain in one sentence why an integral of positive semidefinite matrices is positive semidefinite, naming the two properties of the positive semidefinite matrices that the argument uses.

(c) Decide whether the following is correct, and justify your answer: "a function that extends to an entire function of z and is increasing on $(0,\infty)$ is operator monotone there".

(d) For which real p is $t \mapsto t^p$ operator monotone on $(0,\infty)$? Name the result and say which of its cases needed (A7).

(e) Where in the proof of Theorem 20.10.4 is the hypothesis $\beta \geq 0$ used, and what would go wrong without it?

Solution.

(a) It gives two things: that positivity of all the Loewner matrices of f forces f to extend analytically across the interval preserving the upper half-plane, and that such a function has the integral representation (ii); a third clause says an operator monotone function is automatically C^1. The implications (i) $\Rightarrow$ (iii) and (iii) $\Rightarrow$ (ii) rest on it. The implication (ii) $\Rightarrow$ (i) does not.

(b) Every Riemann sum is a sum of non-negative multiples of the values of the integrand, and the integral is a limit of such sums: the positive semidefinite matrices are closed under non-negative combinations and closed under limits (Lemma 20.10.2).

(c) Incorrect. e^t is entire and increasing on $(0,\infty)$, and is not operator monotone there: Example (The exponential is not operator monotone) gives a witness with spectra in $\mathbb{R}$, and Exercise (B3: Which are operator monotone?) (vi) shifts it into $(0,\infty)$. Condition (iii) of Theorem 20.10.4 asks in addition that the upper half-plane be mapped into its closure, which e^z fails at $z = 3\pi i/2$.

(d) Exactly for $0 \le p \le 1$ (Corollary 20.10.8). No case needed (A7): the positive cases came from Lemma 20.10.5 and Lemma 20.10.2, and the failure for $p > 1$ from Lemma 20.10.6 together with Example (Squaring does not preserve the Loewner order).

(e) In the final display of Step 1, where $\beta\,\mathbf{x}^*(\mathbf{A}-\mathbf{B})\mathbf{x}$ is asserted to be ≥ 0. With $\beta < 0$ that term is ≤ 0 and can dominate: at $n = 1$ the function $f(t) = \beta t$ with $\beta < 0$ is decreasing, hence not operator monotone (Proposition 16.11.1).

20.10.6.2 B. Practice

Exercise B1: One matrix integral.

Let

$$\mathbf{M}(t) = \begin{pmatrix} 2+t & 1 \\ 1 & 2-t \end{pmatrix}, \qquad t \in [-1,1].$$

Show that $\mathbf{M}(t) \succeq 0$ for every $t \in [-1,1]$, compute $\int_{-1}^{1} \mathbf{M}(t)\,dt$, and confirm the conclusion of Lemma 20.10.2 for it.

Solution. $\mathbf{M}(t)$ is real symmetric. Its leading entry is $2+t \ge 1 > 0$ and its determinant is $(2+t)(2-t) - 1 = 3 - t^2 \ge 2 > 0$ for $|t| \le 1$, so $\mathbf{M}(t) \succ 0$ by Sylvester's criterion (Theorem 12.1.5 (d)); in particular $\mathbf{M}(t) \succeq 0$.

Integrating entrywise, $\int_{-1}^{1}(2 \pm t)\,dt = 4$ since $\int_{-1}^{1} t\,dt = 0$, and $\int_{-1}^{1} 1\,dt = 2$. So

$$\int_{-1}^{1} \mathbf{M}(t)\,dt = \begin{pmatrix} 4 & 2 \\ 2 & 4 \end{pmatrix},$$

whose eigenvalues are 6 and 2, both positive; so it is $\succeq 0$ by Theorem 12.1.4 (b), as Lemma 20.10.2 predicts.

Exercise B2: The constant for the square root.

(a) Show that $K_{1/2} = \int_0^\infty u^{-1/2}(1+u)^{-1}du = \pi$. *Hint: substitute* $u = w^2$.

(b) Let $\mathbf{A} = \left(\begin{smallmatrix} 5 & 4 \\ 4 & 5 \end{smallmatrix}\right)$. Using Lemma 20.10.5 with $p = \frac{1}{2}$, evaluate

$$\frac{1}{\pi}\int_0^\infty s^{-1/2}\mathbf{A}(\mathbf{A}+s\mathbf{I})^{-1}\,ds$$

and check the answer against the positive square root of $\mathbf{A}$.

Solution.

(a) With $u = w^2$, so $du = 2w\,dw$ and $u^{-1/2} = 1/w$ for $w > 0$, the substitution rule of

one-variable calculus gives

$$\int_0^\infty \frac{u^{-1/2}}{1+u}\,\mathrm{d}u = \int_0^\infty \frac{1}{w}\cdot\frac{2w}{1+w^2}\,\mathrm{d}w = 2\int_0^\infty \frac{\mathrm{d}w}{1+w^2}.$$

The last integral is $\lim_{R\to\infty}\arctan R - \arctan 0 = \pi/2$, by the fundamental theorem of calculus with the antiderivative arctan. Hence $K_{1/2} = \pi$. (Both calculus facts are quoted, not proved here.)

(b) $\mathbf{A}$ has eigenvalues 9 and 1, with orthonormal eigenvectors $\frac{1}{\sqrt{2}}(1,1)$ and $\frac{1}{\sqrt{2}}(1,-1)$, so its spectral resolution is $\mathbf{A} = 9\mathbf{P}_1 + \mathbf{P}_2$ with

$$\mathbf{P}_1 = \tfrac{1}{2}\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix}, \qquad \mathbf{P}_2 = \tfrac{1}{2}\begin{pmatrix}1 & -1\\ -1 & 1\end{pmatrix}.$$

By the computation in the proof of Corollary 20.10.8, the integral equals $K_{1/2}\mathbf{A}^{1/2}$, so dividing by π gives

$$\mathbf{A}^{1/2} = 9^{1/2}\mathbf{P}_1 + 1^{1/2}\mathbf{P}_2 = 3\mathbf{P}_1 + \mathbf{P}_2 = \begin{pmatrix}2 & 1\\ 1 & 2\end{pmatrix}.$$

Squaring confirms it: $\left(\begin{smallmatrix}2 & 1\\ 1 & 2\end{smallmatrix}\right)^2 = \left(\begin{smallmatrix}5 & 4\\ 4 & 5\end{smallmatrix}\right) = \mathbf{A}$, and the matrix is positive definite, so it is *the* positive square root (Theorem 12.2.1).

Exercise B3: Which are operator monotone?.

Determine which of the following are operator monotone on $(0,\infty)$. Justify your answer.

(i) $f(t) = t^{2/3}$.
(ii) $f(t) = t^{4/3}$.
(iii) $f(t) = 3 + 2\log t$.
(iv) $f(t) = -t^{-1/3}$.
(v) $f(t) = \log(1+t)$.
(vi) $f(t) = e^t$.

Solution.

(i) Operator monotone: $0 \le \frac{2}{3} \le 1$, so Corollary 20.10.8 applies.

(ii) Not operator monotone: $\frac{4}{3} > 1$ (Corollary 20.10.8).

(iii) Operator monotone: log is (Corollary 20.10.9), and $3 + 2\log t$ is $\alpha + c\log t$ with $c = 2 \ge 0$, so Proposition 16.11.4 (a) applies.

(iv) Operator monotone. The function $g(t) = t^{1/3}$ is operator monotone on $(0,\infty)$ with $g((0,\infty)) = (0,\infty)$, and $h(u) = -1/u$ is operator monotone on $(0,\infty)$ (Proposition 16.11.3); by Lemma 20.10.6 the composite $h(g(t)) = -t^{-1/3}$ is operator monotone.

(v) Operator monotone. The affine map $g(t) = t + 1$ is operator monotone on $(0,\infty)$ (Proposition 16.11.2) with image $(1,\infty) \subseteq (0,\infty)$, and log is operator monotone on $(0,\infty)$; apply Lemma 20.10.6.

(vi) Not operator monotone, by Example (The exponential is not operator monotone). (The witness there has spectra in $\mathbb{R}$, not $(0,\infty)$; restrict it by replacing $\mathbf{A}$ and $\mathbf{B}$

with $\mathbf{A}+2\mathbf{I}$ and $\mathbf{B}+2\mathbf{I}$, which are $\succ 0$ and satisfy $e^{\mathbf{A}+2\mathbf{I}} = e^2 e^{\mathbf{A}}$, so the same determinant is negative after multiplication by $e^4 > 0$.)

20.10.6.3 C. Going deeper

Exercise C1: When the integral loses information.

(a) Give a continuous $\mathbf{M}\colon [0,1] \to M_2(\mathbb{R})$ with every $\mathbf{M}(t)$ symmetric, $\int_0^1 \mathbf{M} \succeq 0$, and $\mathbf{M}(t) \not\succeq 0$ for some t. Hence the converse of Lemma 20.10.2 fails.

(b) Prove that if $\mathbf{M}\colon [a,b] \to M_n(\mathbb{C})$ is continuous with $\mathbf{M}(t) \succeq 0$ for every t and $\int_a^b \mathbf{M} = \mathbf{0}$, then $\mathbf{M}(t) = \mathbf{0}$ for every t.

Hint for (b): a continuous non-negative scalar function with zero integral is zero.

Solution.

(a) Take $\mathbf{M}(t) = \operatorname{diag}(1, 2t-1)$. It is continuous and symmetric, $\mathbf{M}(0) = \operatorname{diag}(1,-1)$ is indefinite, and $\int_0^1 \mathbf{M} = \operatorname{diag}(1,0) \succeq 0$.

(b) Fix $\mathbf{x} \in \mathbb{C}^n$ and put $g(t) = \mathbf{x}^* \mathbf{M}(t) \mathbf{x}$, a continuous real-valued function with $g \geq 0$. Because pairing passes inside the integral, $\int_a^b g = \mathbf{x}^* \big(\int_a^b \mathbf{M}\big)\mathbf{x} = 0$. Suppose $g(t_0) > 0$ for some $t_0 \in [a,b]$. By continuity there is a subinterval $[c,d] \subseteq [a,b]$ with $d > c$ on which $g \geq g(t_0)/2$. By interval additivity, $\int_a^b g = \int_a^c g + \int_c^d g + \int_d^b g$, with the outer terms absent if $c = a$ or $d = b$; each outer term is ≥ 0, because $g \geq 0$ and so every Riemann sum over that piece is ≥ 0. On $[c,d]$ every Riemann sum of g is at least $\tfrac{1}{2} g(t_0)(d-c)$, since each tag value is at least $\tfrac{1}{2} g(t_0)$ and the interval lengths sum to $d-c$; a non-strict inequality survives a limit, so $\int_c^d g$ is at least that too. Hence

$$\int_a^b g \;\geq\; \int_c^d g \;\geq\; \frac{g(t_0)}{2}(d-c) \;>\; 0,$$

a contradiction. So $g \equiv 0$, that is $\mathbf{x}^* \mathbf{M}(t) \mathbf{x} = 0$ for every t and every $\mathbf{x}$. A positive semidefinite matrix with $\mathbf{x}^* \mathbf{M} \mathbf{x} = 0$ for every $\mathbf{x}$ is $\mathbf{0}$: by Theorem 12.1.4 (c) write $\mathbf{M}(t) = \mathbf{C}^* \mathbf{C}$, so $\|\mathbf{C}\mathbf{x}\|^2 = 0$ for every $\mathbf{x}$, hence $\mathbf{C} = \mathbf{0}$.

Exercise C2: The cube, by a Loewner matrix.

(a) Write down the Loewner matrix $L_f(t_1, t_2)$ for $f(t) = t^3$ and general $t_1 \neq t_2$, and evaluate its determinant at $t_1 = 1$, $t_2 = 2$. What does Theorem 20.9.5 conclude?

(b) Do the same for $f(t) = t^{1/2}$ at $t_1 = 1$, $t_2 = 4$, and say which result of this section the sign of the determinant illustrates.

Solution.

(a) For $f(t) = t^3$ we have $f'(t) = 3t^2$ and, factoring the difference of cubes,

$$f[t_1, t_2] = \frac{t_1^3 - t_2^3}{t_1 - t_2} = t_1^2 + t_1 t_2 + t_2^2,$$

so $L_f(t_1, t_2)$ has diagonal $(3t_1^2, 3t_2^2)$ and off-diagonal $t_1^2 + t_1 t_2 + t_2^2$ (Definition 20.9.2).

At $t_1 = 1$, $t_2 = 2$ the entries are $3, 12$ and $1 + 2 + 4 = 7$, so

$$\det L_f(1,2) = 3 \cdot 12 - 7^2 = 36 - 49 = -13 < 0.$$

So $L_f(1,2) \not\succeq 0$, and by Theorem 20.9.5 $t \mapsto t^3$ is not monotone of order 2, hence not operator monotone on $(0,\infty)$. This agrees with Corollary 20.10.8, since $3 > 1$.

(b) For $f(t) = t^{1/2}$, $f'(t) = \frac{1}{2}t^{-1/2}$ and

$$f[t_1,t_2] = \frac{\sqrt{t_1} - \sqrt{t_2}}{t_1 - t_2} = \frac{1}{\sqrt{t_1} + \sqrt{t_2}}.$$

At $t_1 = 1$, $t_2 = 4$ the matrix is $\left(\begin{smallmatrix} 1/2 & 1/3 \\ 1/3 & 1/4 \end{smallmatrix}\right)$, with determinant $\frac{1}{8} - \frac{1}{9} = \frac{1}{72} > 0$ and positive diagonal, so it is positive semidefinite. That is consistent with Corollary 20.10.8 at $p = \frac{1}{2}$: an operator monotone function has all its Loewner matrices positive semidefinite, for every size and all points, and this is one instance of it.

Exercise C3: Half of the representation, by hand.

Let $0 < p < 1$, let $\mathbf{A} \succeq \mathbf{B} \succ 0$ be Hermitian in $M_n(F)$, and let $0 < \delta < R$. Put

$$\mathbf{Z}(\delta, R) = \int_\delta^R s^{p-1}\big(\mathbf{A}(\mathbf{A} + s\mathbf{I})^{-1} - \mathbf{B}(\mathbf{B} + s\mathbf{I})^{-1}\big)\,\mathrm{d}s.$$

(a) Prove that $\mathbf{Z}(\delta, R) \succeq 0$ for every such δ, R, **without** any statement about improper integrals.

(b) Deduce $\mathbf{A}^p \succeq \mathbf{B}^p$ from (a) and the convergence statement of Lemma 20.10.5.

(c) Explain why the same argument does not show $\mathbf{A}^2 \succeq \mathbf{B}^2$, by pointing at the step that fails.

Solution.

(a) For each $s \in [\delta, R]$, the function $t \mapsto t/(t+s)$ is operator monotone on $(0,\infty)$ by Corollary 16.11.5, and it sends $\mathbf{A}$ to $\mathbf{A}(\mathbf{A} + s\mathbf{I})^{-1}$ and $\mathbf{B}$ to $\mathbf{B}(\mathbf{B} + s\mathbf{I})^{-1}$ (Definition 11.8.2). So the bracket is $\succeq 0$, and $s^{p-1} > 0$ keeps it so. The integrand is continuous on the compact interval $[\delta, R]$, because each entry is a rational function of s with non-vanishing denominator times s^{p-1}. Hence Lemma 20.10.2 gives $\mathbf{Z}(\delta, R) \succeq 0$.

(b) By Lemma 20.10.5 and the diagonalization in the proof of Corollary 20.10.8, $\mathbf{Z}(\delta, R) \to K_p(\mathbf{A}^p - \mathbf{B}^p)$ entrywise as $\delta \to 0^+$ and $R \to \infty$. For each $\mathbf{x}$, the numbers $\mathbf{x}^*\mathbf{Z}(\delta, R)\mathbf{x}$ are ≥ 0 by (a), and a non-strict inequality survives a limit, so $K_p\,\mathbf{x}^*(\mathbf{A}^p - \mathbf{B}^p)\mathbf{x} \geq 0$; as $K_p > 0$, $\mathbf{A}^p \succeq \mathbf{B}^p$.

(c) The failure is at the very start. For $p = 2$ the integral $\int_0^\infty s^{p-1}\lambda/(\lambda + s)\,\mathrm{d}s$ diverges at $s = \infty$: the integrand behaves like $\lambda s^{p-2} = \lambda$, which is not integrable there. There is no representation of t^2 as a positive superposition of the functions $t/(t+s)$ to begin with — and by Corollary 20.10.8 there cannot be one, since t^2 is not operator monotone.

20.11 Means and Matrix Cauchy–Schwarz

Two inequalities about numbers refuse to die: $|\overline{a}b|^2 \le |a|^2|b|^2$, and $2|\overline{a}b| \le |a|^2 + |b|^2$. For matrices the products do not commute and the absolute values are matrices themselves, so it is not obvious what either statement should say. Sections 4 and 6 have given the right language: measure a matrix by a unitarily invariant norm, and compare two matrices by weak majorization of their singular values. In that language both inequalities survive, for **every** unitarily invariant norm at once. The second half of the section then builds a genuine geometric mean of two positive definite matrices, which is where two order facts from the earlier chapters pay off again: the operator monotonicity of $t \mapsto t^{1/2}$ from Chapter 12 §05 and that of $t \mapsto -1/t$ from Chapter 16 §11.

Throughout, $F = \mathbb{R}$ or $F = \mathbb{C}$ and all matrices are $n \times n$ over F, with $|||\cdot|||$ an arbitrary unitarily invariant norm on $M_n(F)$ (Definition 20.4.1). As always $\sigma_1(\mathbf{A}) \ge \cdots \ge \sigma_n(\mathbf{A}) \ge 0$ are the singular values in decreasing order and $\lambda_1(\mathbf{A}) \ge \cdots \ge \lambda_n(\mathbf{A})$ the eigenvalues of a Hermitian $\mathbf{A}$; for $\mathbf{A} \succeq 0$ the two lists agree. The order $\succeq$ is the Loewner order (Definition 12.5.1).

20.11.1 An off-diagonal block is small

Everything in the first half comes from one observation about a positive semidefinite matrix cut into four blocks: the corner blocks control the off-diagonal one, and they do so eigenvalue by eigenvalue.

Lemma 20.11.1 — The Off-Diagonal Block of a Positive Semidefinite Matrix

Let $k, l \ge 1$, let $\mathbf{P} \in M_k(F)$, $\mathbf{Q} \in M_l(F)$ and $\mathbf{X} \in M_{k\times l}(F)$, and suppose that

$$\mathbf{M} = \begin{pmatrix} \mathbf{P} & \mathbf{X} \\ \mathbf{X}^* & \mathbf{Q} \end{pmatrix} \succeq 0.$$

Then $2\sigma_j(\mathbf{X}) \le \lambda_j(\mathbf{M})$ for every $j = 1, \dots, \min(k, l)$.

Idea. Flipping the sign of the second block of coordinates is a unitary congruence, so it turns $\mathbf{M}$ into another positive semidefinite matrix — the same one with $\mathbf{X}$ replaced by $-\mathbf{X}$. Half the difference of the two is the Hermitian dilation of $\mathbf{X}$, whose eigenvalues are exactly $\pm\sigma_i(\mathbf{X})$ and zeros. Since what was subtracted is itself positive semidefinite, the dilation is dominated by $\frac{1}{2}\mathbf{M}$ in the Loewner order, and Chapter 16 §02 turns that into a comparison of eigenvalues index by index.

Proof. Put $\mathbf{S} = \mathbf{I}_k \oplus (-\mathbf{I}_l)$, which is Hermitian and unitary. By Theorem 7.1.1,

$$\mathbf{S}^*\mathbf{M}\mathbf{S} = \begin{pmatrix} \mathbf{P} & -\mathbf{X} \\ -\mathbf{X}^* & \mathbf{Q} \end{pmatrix},$$

and $\mathbf{S}^*\mathbf{M}\mathbf{S} \succeq 0$ because a congruence by an invertible matrix preserves positive semidef-

initeness (Proposition 12.1.2 (a)). Subtracting,

$$\tfrac{1}{2}\big(\mathbf{M} - \mathbf{S}^{*}\mathbf{M}\mathbf{S}\big) = \begin{pmatrix} \mathbf{0} & \mathbf{X} \\ \mathbf{X}^{*} & \mathbf{0} \end{pmatrix} = \mathcal{H}(\mathbf{X}),$$

the Hermitian dilation of $\mathbf{X}$ (Proposition 16.9.3). Since $\tfrac{1}{2}\mathbf{S}^{*}\mathbf{M}\mathbf{S} \succeq 0$, this says

$$\mathcal{H}(\mathbf{X}) = \tfrac{1}{2}\mathbf{M} - \tfrac{1}{2}\mathbf{S}^{*}\mathbf{M}\mathbf{S} \preceq \tfrac{1}{2}\mathbf{M}.$$

By Corollary 16.2.4 the Loewner order compares every eigenvalue, so $\lambda_j(\mathcal{H}(\mathbf{X})) \le \lambda_j(\tfrac{1}{2}\mathbf{M}) = \tfrac{1}{2}\lambda_j(\mathbf{M})$ for every j.

Finally, by Proposition 16.9.3 the eigenvalues of $\mathcal{H}(\mathbf{X})$, with multiplicity, are $\pm\sigma_1(\mathbf{X}), \dots, \pm\sigma_p(\mathbf{X})$ together with $k + l - 2p$ zeros, where $p = \min(k, l)$. Sorted decreasingly, the first p of them are $\sigma_1(\mathbf{X}) \ge \cdots \ge \sigma_p(\mathbf{X})$, since every remaining entry is $\le 0 \le \sigma_p(\mathbf{X})$. Hence $\lambda_j(\mathcal{H}(\mathbf{X})) = \sigma_j(\mathbf{X})$ for $j \le p$, and the displayed inequality reads $2\sigma_j(\mathbf{X}) \le \lambda_j(\mathbf{M})$.

■

20.11.2 A product against a sum of squares

The lemma becomes an inequality about products as soon as one remembers where positive semidefinite block matrices come from: $\mathbf{D}^{*}\mathbf{D}$, for $\mathbf{D}$ the block row built from the two matrices in question.

Theorem 20.11.2 — Arithmetic–Geometric Mean Inequality for Matrices

Let $\mathbf{A}, \mathbf{B} \in M_n(F)$. Then

$$2\sigma_j(\mathbf{A}^{*}\mathbf{B}) \le \lambda_j(\mathbf{A}\mathbf{A}^{*} + \mathbf{B}\mathbf{B}^{*}) \qquad (j = 1, \dots, n),$$

and consequently, for every unitarily invariant norm on $M_n(F)$,

$$2\,|||\mathbf{A}^{*}\mathbf{B}||| \le |||\mathbf{A}\mathbf{A}^{*} + \mathbf{B}\mathbf{B}^{*}|||.$$

Idea. Put the two matrices side by side in one $n \times 2n$ block row $\mathbf{D} = (\mathbf{A}\ \ \mathbf{B})$. Then $\mathbf{D}^{*}\mathbf{D}$ is the $2n \times 2n$ positive semidefinite matrix whose off-diagonal block is exactly $\mathbf{A}^{*}\mathbf{B}$, so Lemma 20.11.1 applies; and $\mathbf{D}\mathbf{D}^{*}$, which has the same non-zero eigenvalues, is the sum $\mathbf{A}\mathbf{A}^{*} + \mathbf{B}\mathbf{B}^{*}$. The norm statement is then the singular value statement read through §06's dominance theorem.

Proof. Let $\mathbf{D} = (\mathbf{A}\ \ \mathbf{B}) \in M_{n\times 2n}(F)$, the block row with $\mathbf{A}$ then $\mathbf{B}$. By Theorem 7.1.1,

$$\mathbf{D}^{*}\mathbf{D} = \begin{pmatrix} \mathbf{A}^{*}\mathbf{A} & \mathbf{A}^{*}\mathbf{B} \\ \mathbf{B}^{*}\mathbf{A} & \mathbf{B}^{*}\mathbf{B} \end{pmatrix}, \qquad \mathbf{D}\mathbf{D}^{*} = \mathbf{A}\mathbf{A}^{*} + \mathbf{B}\mathbf{B}^{*}.$$

The matrix $\mathbf{D}^{*}\mathbf{D}$ is Hermitian and satisfies $\mathbf{x}^{*}\mathbf{D}^{*}\mathbf{D}\mathbf{x} = \|\mathbf{D}\mathbf{x}\|^2 \ge 0$ for every $\mathbf{x} \in F^{2n}$, so $\mathbf{D}^{*}\mathbf{D} \succeq 0$ (Definition 12.1.1). Its off-diagonal block is $\mathbf{A}^{*}\mathbf{B}$, so Lemma 20.11.1 with $k = l = n$ gives

$$2\sigma_j(\mathbf{A}^{*}\mathbf{B}) \le \lambda_j(\mathbf{D}^{*}\mathbf{D}) \qquad (j = 1, \dots, n).$$

It remains to identify $\lambda_j(\mathbf{D}^*\mathbf{D})$ with $\lambda_j(\mathbf{D}\mathbf{D}^*)$ for $j \le n$. Applying Theorem 8.10.4 to the pair $\mathbf{D}^* \in M_{2n\times n}$ and $\mathbf{D} \in M_{n\times 2n}$ gives $x^n p_{\mathbf{D}^*\mathbf{D}}(x) = x^{2n} p_{\mathbf{D}\mathbf{D}^*}(x)$, that is $p_{\mathbf{D}^*\mathbf{D}} = x^n p_{\mathbf{D}\mathbf{D}^*}$: the eigenvalue list of $\mathbf{D}^*\mathbf{D}$ is that of $\mathbf{D}\mathbf{D}^*$ with n extra zeros. Both matrices are positive semidefinite, so all their eigenvalues are ≥ 0 (Theorem 12.1.4 (b)) and the first n entries of the two decreasing lists agree. This proves the first display.

For the second, both $2\mathbf{A}^*\mathbf{B}$ and $\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*$ lie in $M_n(F)$, and the singular values of the positive semidefinite $\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*$ are its eigenvalues. So the first display says $\sigma_j(2\mathbf{A}^*\mathbf{B}) \le \sigma_j(\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*)$ for every j. Two decreasing lists of non-negative numbers with the first dominated entry by entry satisfy $\sigma(2\mathbf{A}^*\mathbf{B}) \prec_w \sigma(\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*)$, since each top-$k$ partial sum is dominated term by term (Definition 16.8.1). Now Theorem 20.6.1 turns that weak majorization into $\|2\mathbf{A}^*\mathbf{B}\| \le \|\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*\|$, and $\|2\mathbf{A}^*\mathbf{B}\| = 2\,\|\mathbf{A}^*\mathbf{B}\|$ by homogeneity of a norm.

■

Warning. **The two sums are not interchangeable.** It is tempting to write $\mathbf{A}^*\mathbf{A} + \mathbf{B}^*\mathbf{B}$ on the right, since that is what pairs with $\mathbf{A}^*\mathbf{B}$ in the block matrix $\mathbf{D}^*\mathbf{D}$. The resulting statement is **false**. Take

$$\mathbf{A} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Then $\mathbf{A}^*\mathbf{A} = \operatorname{diag}(1,0)$ and $\mathbf{B}^*\mathbf{B} = \operatorname{diag}(0,1)$, so $\mathbf{A}^*\mathbf{A} + \mathbf{B}^*\mathbf{B} = \mathbf{I}$ and $\|\mathbf{I}\|_2 = 1$; while $\mathbf{A}^*\mathbf{B} = \mathbf{B}$ has $\|\mathbf{B}\|_2 = 1$, so $2\,\|\mathbf{A}^*\mathbf{B}\| = 2 > 1$ in the spectral norm. The correct right-hand side is $\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^* = \operatorname{diag}(2,0)$, of spectral norm 2 — and here the inequality is an equality.

20.11.3 Cauchy–Schwarz

Theorem 20.11.3 — Cauchy–Schwarz for Unitarily Invariant Norms

Let $\mathbf{A}, \mathbf{B} \in M_n(F)$. Then for every unitarily invariant norm on $M_n(F)$,

$$\|\mathbf{A}^*\mathbf{B}\|^2 \;\le\; \|\mathbf{A}^*\mathbf{A}\|\;\|\mathbf{B}^*\mathbf{B}\|.$$

Idea. The scalar inequality $2|\overline{a}b| \le |a|^2 + |b|^2$ becomes $|\overline{a}b| \le |a||b|$ by the classical trick of replacing a by ta and b by b/t and choosing t to balance the two terms. The product $\mathbf{A}^*\mathbf{B}$ is unchanged by that substitution, so the same trick upgrades Theorem 20.11.2. The one thing to check is that the two sides of the balance are the right quantities, and that is the identity $\|\mathbf{A}\mathbf{A}^*\| = \|\mathbf{A}^*\mathbf{A}\|$.

Proof. Put $a = \|\mathbf{A}^*\mathbf{A}\|$ and $b = \|\mathbf{B}^*\mathbf{B}\|$. If $a = 0$, then $\mathbf{A}^*\mathbf{A} = \mathbf{0}$ by the positivity clause of Definition 15.1.1, so $\|\mathbf{A}\mathbf{x}\|^2 = \mathbf{x}^*\mathbf{A}^*\mathbf{A}\mathbf{x} = 0$ for every $\mathbf{x}$ and $\mathbf{A} = \mathbf{0}$; then both sides of the asserted inequality are 0. Likewise if $b = 0$. So assume $a > 0$ and $b > 0$.

First, $\|\mathbf{A}\mathbf{A}^*\| = \|\mathbf{A}^*\mathbf{A}\|$. Indeed $\mathbf{A}\mathbf{A}^*$ and $\mathbf{A}^*\mathbf{A}$ are positive semidefinite with the same eigenvalues, namely $\sigma_i(\mathbf{A})^2$ (Definition 12.8.1 and Theorem 8.10.4 (b), the two matrices being of equal size n), hence the same singular values; and a unitarily invariant norm depends only on the singular values (Lemma 20.4.1).

Let $t > 0$ and apply Theorem 20.11.2 to the pair $t\mathbf{A}$ and $t^{-1}\mathbf{B}$. Their product is $(t\mathbf{A})^*(t^{-1}\mathbf{B}) = \mathbf{A}^*\mathbf{B}$, unchanged, while

$$(t\mathbf{A})(t\mathbf{A})^* + (t^{-1}\mathbf{B})(t^{-1}\mathbf{B})^* = t^2\mathbf{A}\mathbf{A}^* + t^{-2}\mathbf{B}\mathbf{B}^*.$$

So, using the triangle inequality and homogeneity of $|||\cdot|||$ and then the identity just proved,

$$2\,|||\mathbf{A}^*\mathbf{B}||| \;\le\; t^2\,|||\mathbf{A}\mathbf{A}^*||| + t^{-2}\,|||\mathbf{B}\mathbf{B}^*||| = t^2 a + t^{-2} b.$$

By the arithmetic–geometric mean inequality for two positive numbers (Lemma 16.8.6), $t^2 a + t^{-2} b \ge 2\sqrt{ab}$, with equality when $t^2 a = t^{-2} b$; choosing $t = (b/a)^{1/4}$, which is legitimate since $a, b > 0$, makes the two terms equal and gives

$$2\,|||\mathbf{A}^*\mathbf{B}||| \;\le\; 2\sqrt{ab}.$$

Dividing by 2 and squaring proves the theorem.

■

Remark. Three familiar inequalities are special cases. With $|||\cdot||| = \|\cdot\|_F$ it is $\|\mathbf{A}^*\mathbf{B}\|_F^2 \le \|\mathbf{A}^*\mathbf{A}\|_F \|\mathbf{B}^*\mathbf{B}\|_F$; with the spectral norm it is $\|\mathbf{A}^*\mathbf{B}\|_2^2 \le \|\mathbf{A}\|_2^2 \|\mathbf{B}\|_2^2$, which also follows from submultiplicativity; and with the trace norm $|||\cdot|||_{(n)} = \sum_i \sigma_i(\cdot)$ it compares $\sum_i \sigma_i(\mathbf{A}^*\mathbf{B})$ with $\big(\sum_i \sigma_i(\mathbf{A})^2\big)^{1/2}\big(\sum_i \sigma_i(\mathbf{B})^2\big)^{1/2}$. At $n = 1$ all of them are $|\overline{a}b|^2 \le |a|^2|b|^2$.

20.11.4 The geometric mean of two positive definite matrices

The inequalities above were about *norms* of products. The rest of the section is about an operation: given $\mathbf{A}, \mathbf{B} \succ 0$, produce a positive definite matrix that deserves the name $\sqrt{\mathbf{A}\mathbf{B}}$.

The arithmetic mean gives no trouble: $\tfrac{1}{2}(\mathbf{A} + \mathbf{B})$ is positive definite, symmetric in the two arguments, and monotone in each. The geometric mean is the problem. The naive candidate is $(\mathbf{A}\mathbf{B})^{1/2}$, and it does not exist: $\mathbf{A}\mathbf{B}$ need not be Hermitian, so Theorem 12.2.1 has nothing to say about it. The next candidate, $\mathbf{A}^{1/2}\mathbf{B}^{1/2}$, is a matrix, but usually not a Hermitian one. What works is to measure $\mathbf{B}$ in the coordinates that make $\mathbf{A}$ the identity, take the square root there, and translate back.

The geometric mean of two positive definite matrices is the square root of the second one, computed after the first has been turned into the identity, and then translated back.

Definition 20.11.1 — Geometric Mean of Positive Definite Matrices

Let $\mathbf{A}, \mathbf{B} \in M_n(F)$ with $\mathbf{A} \succ 0$ and $\mathbf{B} \succ 0$. Their **geometric mean** is

$$\mathbf{A}\#\mathbf{B} \;:=\; \mathbf{A}^{1/2}\big(\mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2}\big)^{1/2}\mathbf{A}^{1/2},$$

where $\mathbf{A}^{1/2}$ is the positive square root of Theorem 12.2.1, $\mathbf{A}^{-1/2} := (\mathbf{A}^{1/2})^{-1}$, and the

outer exponent $\frac{1}{2}$ is again the positive square root.

In words: conjugate $\mathbf{B}$ by $\mathbf{A}^{-1/2}$ — this is the **whitening** move of Chapter 12 §05, which replaces the pair $(\mathbf{A}, \mathbf{B})$ by $(\mathbf{I}, \mathbf{C})$ with $\mathbf{C} = \mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2}$ — take the positive square root of $\mathbf{C}$, and undo the conjugation.

Everything in the definition makes sense. $\mathbf{A} \succ 0$ gives $\mathbf{A}^{1/2} \succ 0$ (its eigenvalues are the positive square roots of those of $\mathbf{A}$, by Theorem 12.2.1), so $\mathbf{A}^{1/2}$ is invertible and $\mathbf{A}^{-1/2}$ is Hermitian. Hence $\mathbf{C} = \mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2} = (\mathbf{A}^{-1/2})^{*}\mathbf{B}\mathbf{A}^{-1/2}$ is a congruence of $\mathbf{B} \succ 0$ by an invertible matrix and is therefore $\succ 0$ (Proposition 12.1.2 (b)); so $\mathbf{C}^{1/2}$ exists, is unique, and is $\succ 0$. Finally $\mathbf{A}\#\mathbf{B} = (\mathbf{A}^{1/2})^{*}\mathbf{C}^{1/2}\mathbf{A}^{1/2}$ is another such congruence, so $\mathbf{A}\#\mathbf{B} \succ 0$. In particular $\mathbf{A}\#\mathbf{B}$ is Hermitian, which $\mathbf{A}^{1/2}\mathbf{B}^{1/2}$ is not.

Examples.

- **Numbers.** For $n = 1$ with $\mathbf{A} = (a)$, $\mathbf{B} = (b)$ and $a, b > 0$, the formula reads $\sqrt{a}\,(b/a)^{1/2}\sqrt{a} = \sqrt{ab}$. This is where the name comes from.
- **One argument the identity.** $\mathbf{A}\#\mathbf{I} = \mathbf{A}^{1/2}(\mathbf{A}^{-1})^{1/2}\mathbf{A}^{1/2} = \mathbf{A}^{1/2}\mathbf{A}^{-1/2}\mathbf{A}^{1/2} = \mathbf{A}^{1/2}$, using $(\mathbf{A}^{-1})^{1/2} = \mathbf{A}^{-1/2}$, which holds because $(\mathbf{A}^{-1/2})^2 = \mathbf{A}^{-1}$ and $\mathbf{A}^{-1/2} \succ 0$, so uniqueness in Theorem 12.2.1 applies. Likewise $\mathbf{A}\#\mathbf{A} = \mathbf{A}^{1/2}\mathbf{I}\mathbf{A}^{1/2} = \mathbf{A}$.
- **Commuting arguments.** If $\mathbf{A}\mathbf{B} = \mathbf{B}\mathbf{A}$ then $\mathbf{A}\#\mathbf{B} = (\mathbf{A}\mathbf{B})^{1/2}$. Indeed $\mathbf{A}^{1/2}$ commutes with $\mathbf{B}$ (Theorem 12.2.1 (b)), hence so does $\mathbf{A}^{-1/2}$, so $\mathbf{C} = \mathbf{B}\mathbf{A}^{-1}$ commutes with $\mathbf{A}$, and $\mathbf{C}^{1/2}$, being a polynomial in $\mathbf{C}$ (Theorem 12.2.1 (a)), commutes with $\mathbf{A}$ too. Therefore

$$\begin{aligned}(\mathbf{A}\#\mathbf{B})^2 &= \mathbf{A}^{1/2}\mathbf{C}^{1/2}\mathbf{A}\,\mathbf{C}^{1/2}\mathbf{A}^{1/2} = \mathbf{A}^{1/2}\mathbf{A}\,\mathbf{C}\,\mathbf{A}^{1/2}\\ &= \mathbf{A}^{1/2}\mathbf{A}\mathbf{B}\mathbf{A}^{-1}\mathbf{A}^{1/2} = \mathbf{A}^{1/2}\mathbf{B}\mathbf{A}^{1/2} = \mathbf{A}\mathbf{B},\end{aligned}$$

  using $\mathbf{C} = \mathbf{B}\mathbf{A}^{-1}$ and $\mathbf{A}\mathbf{B} = \mathbf{B}\mathbf{A}$ once more; and $\mathbf{A}\#\mathbf{B} \succ 0$, so it is the positive square root of $\mathbf{A}\mathbf{B}$. For instance $\operatorname{diag}(4,1)\#\operatorname{diag}(1,9) = \operatorname{diag}(2,3)$.
- **A non-commuting pair, exactly.** Let

$$\mathbf{A} = \begin{pmatrix} 5 & 4 \\ 4 & 5 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 8 & 10 \\ 10 & 17 \end{pmatrix}.$$

  Then $\mathbf{A}^{1/2} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$, and $\mathbf{A}^{-1/2} = \frac{1}{3}\left(\begin{smallmatrix} 2 & -1 \\ -1 & 2 \end{smallmatrix}\right)$, so $\mathbf{C} = \mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2} = \operatorname{diag}(1,4)$ and $\mathbf{C}^{1/2} = \operatorname{diag}(1,2)$. Hence

$$\mathbf{A}\#\mathbf{B} = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}\begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix} = \begin{pmatrix} 6 & 6 \\ 6 & 9 \end{pmatrix}.$$

  Here $\mathbf{A}\mathbf{B} \neq \mathbf{B}\mathbf{A}$, as the $(1,2)$ entries 118 and 82 show. Note $\det(\mathbf{A}\#\mathbf{B}) = 18 = \sqrt{9 \cdot 36} = \sqrt{\det\mathbf{A}\,\det\mathbf{B}}$; Exercise C1 explains why.

A non-example by minimal change. Drop the middle square root and take $\mathbf{A}^{1/2}\mathbf{B}^{1/2}$. With $\mathbf{A} = \operatorname{diag}(4,1)$ and $\mathbf{B} = \left(\begin{smallmatrix} 5 & 4 \\ 4 & 5 \end{smallmatrix}\right)$, the two square roots are $\operatorname{diag}(2,1)$ and $\left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$, and

$$\mathbf{A}^{1/2}\mathbf{B}^{1/2} = \begin{pmatrix} 4 & 2 \\ 1 & 2 \end{pmatrix},$$

which is not Hermitian, so it is not $\succ 0$ and is not a mean of anything. Its square is $\left(\begin{smallmatrix} 18 & 12 \\ 6 & 6 \end{smallmatrix}\right)$, not $\mathbf{A}\mathbf{B} = \left(\begin{smallmatrix} 20 & 16 \\ 4 & 5 \end{smallmatrix}\right)$.

Warning. **Half of A times half of B is not a mean.** $\mathbf{A}^{1/2}\mathbf{B}^{1/2}$ is Hermitian only when $\mathbf{A}$ and $\mathbf{B}$ commute: $(\mathbf{A}^{1/2}\mathbf{B}^{1/2})^* = \mathbf{B}^{1/2}\mathbf{A}^{1/2}$, and if this equals $\mathbf{A}^{1/2}\mathbf{B}^{1/2}$, then squaring gives $\mathbf{AB} = \mathbf{BA}$. The sandwich in Definition 20.11.1 exists precisely to repair this, and the price is that the formula no longer *looks* symmetric in $\mathbf{A}$ and $\mathbf{B}$. It is; that is the content of Theorem 20.11.4 (b), and it is the one property here that needs an argument.

Quick check. Compute $\mathbf{A}\#\mathbf{B}$ for $\mathbf{A} = \operatorname{diag}(4,1)$ and $\mathbf{B} = \operatorname{diag}(1,9)$ straight from Definition 20.11.1, and check the answer against $(\mathbf{AB})^{1/2}$.

Solution. $\mathbf{A}^{1/2} = \operatorname{diag}(2,1)$ and $\mathbf{A}^{-1/2} = \operatorname{diag}(\tfrac{1}{2},1)$, so $\mathbf{C} = \mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2} = \operatorname{diag}(\tfrac{1}{4},9)$ and $\mathbf{C}^{1/2} = \operatorname{diag}(\tfrac{1}{2},3)$. Hence

$$\mathbf{A}\#\mathbf{B} = \operatorname{diag}(2,1)\operatorname{diag}(\tfrac{1}{2},3)\operatorname{diag}(2,1) = \operatorname{diag}(2,3).$$

The two matrices commute, and $\mathbf{AB} = \operatorname{diag}(4,9)$, whose positive square root is $\operatorname{diag}(2,3)$. The two agree.

20.11.5 What the geometric mean does

The key is a description of $\mathbf{A}\#\mathbf{B}$ that never mentions $\mathbf{A}^{1/2}$. Chapter 12 §06's block test supplies it.

Theorem 20.11.4 — Properties of the Geometric Mean

Let $\mathbf{A},\mathbf{B},\mathbf{A}',\mathbf{B}' \in M_n(F)$ be positive definite and let $\mathbf{S} \in M_n(F)$ be invertible.

(a) **Extremal characterization.** $\mathbf{A}\#\mathbf{B}$ is the largest Hermitian $\mathbf{X} \in M_n(F)$ for which

$$\begin{pmatrix} \mathbf{A} & \mathbf{X} \\ \mathbf{X} & \mathbf{B} \end{pmatrix} \succeq 0 :$$

this holds for $\mathbf{X} = \mathbf{A}\#\mathbf{B}$, and every Hermitian $\mathbf{X}$ for which it holds satisfies $\mathbf{X} \preceq \mathbf{A}\#\mathbf{B}$.

(b) **Symmetry.** $\mathbf{A}\#\mathbf{B} = \mathbf{B}\#\mathbf{A}$.

(c) **Congruence.** $(\mathbf{S}^*\mathbf{A}\mathbf{S})\#(\mathbf{S}^*\mathbf{B}\mathbf{S}) = \mathbf{S}^*(\mathbf{A}\#\mathbf{B})\mathbf{S}$.

(d) **Monotonicity.** If $\mathbf{A} \succeq \mathbf{A}'$ and $\mathbf{B} \succeq \mathbf{B}'$, then $\mathbf{A}\#\mathbf{B} \succeq \mathbf{A}'\#\mathbf{B}'$.

(e) **Arithmetic–geometric mean, and inversion.** $\mathbf{A}\#\mathbf{B} \preceq \tfrac{1}{2}(\mathbf{A}+\mathbf{B})$, and $(\mathbf{A}\#\mathbf{B})^{-1} = \mathbf{A}^{-1}\#\mathbf{B}^{-1}$.

Idea. Everything rests on (a), and (a) rests on whitening. With $\mathbf{A} \succ 0$ the block test Theorem 12.6.1 turns the block condition into $\mathbf{B} - \mathbf{X}\mathbf{A}^{-1}\mathbf{X} \succeq 0$; substituting $\mathbf{X} = \mathbf{A}^{1/2}\mathbf{Y}\mathbf{A}^{1/2}$ and conjugating by $\mathbf{A}^{-1/2}$ turns *that* into $\mathbf{Y}^2 \preceq \mathbf{C}$, with $\mathbf{C} = \mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2}$. The largest Hermitian $\mathbf{Y}$ with $\mathbf{Y}^2 \preceq \mathbf{C}$ is $\mathbf{C}^{1/2}$, because $\mathbf{Y} \preceq |\mathbf{Y}| = (\mathbf{Y}^2)^{1/2}$ and the square root is operator monotone. Once (a) is available, (b), (c) and (d) are all statements about the *set* of admissible $\mathbf{X}$, and they read off the symmetry, the congruence-invariance and the monotonicity of that set without any further computation.

Proof. Write $\mathbf{C} = \mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2} \succ 0$, so that $\mathbf{A}\#\mathbf{B} = \mathbf{A}^{1/2}\mathbf{C}^{1/2}\mathbf{A}^{1/2}$, and for Hermitian $\mathbf{X}$ put

$$\mathbf{M}(\mathbf{X}) = \begin{pmatrix} \mathbf{A} & \mathbf{X} \\ \mathbf{X} & \mathbf{B} \end{pmatrix},$$

which is Hermitian because $\mathbf{X}^* = \mathbf{X}$. Call $\mathbf{X}$ **admissible** for $(\mathbf{A}, \mathbf{B})$ when $\mathbf{M}(\mathbf{X}) \succeq 0$.

(a). Since $\mathbf{A} \succ 0$, Theorem 12.6.1 (b) says that $\mathbf{X}$ is admissible exactly when the Schur complement $\mathbf{B} - \mathbf{X}\mathbf{A}^{-1}\mathbf{X}$ is $\succeq 0$. Every Hermitian $\mathbf{X}$ is uniquely $\mathbf{X} = \mathbf{A}^{1/2}\mathbf{Y}\mathbf{A}^{1/2}$ with $\mathbf{Y} = \mathbf{A}^{-1/2}\mathbf{X}\mathbf{A}^{-1/2}$ Hermitian, and then

$$\mathbf{X}\mathbf{A}^{-1}\mathbf{X} = \mathbf{A}^{1/2}\mathbf{Y}\mathbf{A}^{1/2}\mathbf{A}^{-1}\mathbf{A}^{1/2}\mathbf{Y}\mathbf{A}^{1/2} = \mathbf{A}^{1/2}\mathbf{Y}^2\mathbf{A}^{1/2}.$$

Conjugating by the invertible Hermitian $\mathbf{A}^{-1/2}$ and using Proposition 12.1.2 (a) in both directions,

$$\mathbf{B} - \mathbf{A}^{1/2}\mathbf{Y}^2\mathbf{A}^{1/2} \succeq 0 \quad \Longleftrightarrow \quad \mathbf{C} - \mathbf{Y}^2 \succeq 0.$$

Claim. If $\mathbf{Y}$ is Hermitian and $\mathbf{Y}^2 \preceq \mathbf{C}$, then $\mathbf{Y} \preceq \mathbf{C}^{1/2}$.

Proof. Let $\mathbf{Y} = \sum_j \mu_j \mathbf{P}_j$ be the spectral resolution (Theorem 11.8.1), so that $\mathbf{Y}^2 = \sum_j \mu_j^2 \mathbf{P}_j$ and the matrix $\sum_j |\mu_j| \mathbf{P}_j$ is $\succeq 0$ with square $\mathbf{Y}^2$; by uniqueness in Theorem 12.2.1 it is $(\mathbf{Y}^2)^{1/2}$. Then

$$(\mathbf{Y}^2)^{1/2} - \mathbf{Y} = \sum_j \bigl(|\mu_j| - \mu_j\bigr)\mathbf{P}_j \;\succeq\; 0,$$

because $\mathbf{x}^*\mathbf{P}_j\mathbf{x} = \|\mathbf{P}_j\mathbf{x}\|^2 \geq 0$ and every coefficient is ≥ 0. So $\mathbf{Y} \preceq (\mathbf{Y}^2)^{1/2}$. Also $\mathbf{Y}^2 \preceq \mathbf{C}$ with $\mathbf{Y}^2 \succeq 0$, so Proposition 12.5.4 gives $(\mathbf{Y}^2)^{1/2} \preceq \mathbf{C}^{1/2}$. Chaining the two (Proposition 12.5.1) gives $\mathbf{Y} \preceq \mathbf{C}^{1/2}$.

■

The choice $\mathbf{Y} = \mathbf{C}^{1/2}$ itself satisfies $\mathbf{C} - \mathbf{Y}^2 = \mathbf{0} \succeq 0$. So among the Hermitian $\mathbf{Y}$ with $\mathbf{C} - \mathbf{Y}^2 \succeq 0$ the largest is $\mathbf{C}^{1/2}$. Translating back by the order-preserving bijection $\mathbf{Y} \mapsto \mathbf{A}^{1/2}\mathbf{Y}\mathbf{A}^{1/2}$ (again Proposition 12.1.2 (a), in both directions), the largest admissible $\mathbf{X}$ is $\mathbf{A}^{1/2}\mathbf{C}^{1/2}\mathbf{A}^{1/2} = \mathbf{A}\#\mathbf{B}$.

(b). Let $\mathbf{W} = \left(\begin{smallmatrix} \mathbf{0} & \mathbf{I} \\ \mathbf{I} & \mathbf{0} \end{smallmatrix}\right)$, which is Hermitian and unitary, hence invertible. By Theorem 7.1.1,

$$\mathbf{W}^* \begin{pmatrix} \mathbf{A} & \mathbf{X} \\ \mathbf{X} & \mathbf{B} \end{pmatrix} \mathbf{W} = \begin{pmatrix} \mathbf{B} & \mathbf{X} \\ \mathbf{X} & \mathbf{A} \end{pmatrix},$$

so by Proposition 12.1.2 (a), applied to $\mathbf{W}$ and to $\mathbf{W}^{-1}$, a Hermitian $\mathbf{X}$ is admissible for $(\mathbf{A}, \mathbf{B})$ if and only if it is admissible for $(\mathbf{B}, \mathbf{A})$. The two admissible sets coincide, so they have the same largest element; by (a) that element is $\mathbf{A}\#\mathbf{B}$ on one side and $\mathbf{B}\#\mathbf{A}$ on the other, and a partial order has at most one largest element (Proposition 12.5.1).

(c). Put $\mathbf{T} = \mathbf{S} \oplus \mathbf{S}$. By Theorem 7.1.1,

$$\mathbf{T}^* \begin{pmatrix} \mathbf{A} & \mathbf{X} \\ \mathbf{X} & \mathbf{B} \end{pmatrix} \mathbf{T} = \begin{pmatrix} \mathbf{S}^*\mathbf{A}\mathbf{S} & \mathbf{S}^*\mathbf{X}\mathbf{S} \\ \mathbf{S}^*\mathbf{X}\mathbf{S} & \mathbf{S}^*\mathbf{B}\mathbf{S} \end{pmatrix},$$

and $\mathbf{T}$ is invertible, so $\mathbf{X}$ is admissible for $(\mathbf{A},\mathbf{B})$ exactly when $\mathbf{S}^*\mathbf{X}\mathbf{S}$ is admissible for $(\mathbf{S}^*\mathbf{A}\mathbf{S},\mathbf{S}^*\mathbf{B}\mathbf{S})$ (Proposition 12.1.2 (a), both ways). The map $\mathbf{X}\mapsto\mathbf{S}^*\mathbf{X}\mathbf{S}$ is a bijection of the Hermitian matrices that preserves $\preceq$ in both directions, so it carries the largest element of one admissible set to the largest element of the other. Both $\mathbf{S}^*\mathbf{A}\mathbf{S}$ and $\mathbf{S}^*\mathbf{B}\mathbf{S}$ are $\succ 0$ by Proposition 12.1.2 (b), so (a) applies to them, and the claim follows.

(d). Let $\mathbf{X}$ be admissible for $(\mathbf{A}',\mathbf{B}')$. Then

$$\begin{pmatrix}\mathbf{A} & \mathbf{X}\\ \mathbf{X} & \mathbf{B}\end{pmatrix} = \begin{pmatrix}\mathbf{A}' & \mathbf{X}\\ \mathbf{X} & \mathbf{B}'\end{pmatrix} + \begin{pmatrix}\mathbf{A}-\mathbf{A}' & \mathbf{0}\\ \mathbf{0} & \mathbf{B}-\mathbf{B}'\end{pmatrix},$$

a sum of two positive semidefinite matrices — the second because its quadratic form is $\mathbf{y}_1^*(\mathbf{A}-\mathbf{A}')\mathbf{y}_1+\mathbf{y}_2^*(\mathbf{B}-\mathbf{B}')\mathbf{y}_2\ge 0$. So $\mathbf{X}$ is admissible for $(\mathbf{A},\mathbf{B})$. Taking $\mathbf{X}=\mathbf{A}'\#\mathbf{B}'$, which is admissible for $(\mathbf{A}',\mathbf{B}')$ by (a), gives $\mathbf{A}'\#\mathbf{B}'\preceq\mathbf{A}\#\mathbf{B}$ by the maximality in (a).

(e). Since $\mathbf{C}^{1/2}$ is Hermitian, $(\mathbf{I}-\mathbf{C}^{1/2})^2\succeq 0$ by Theorem 12.1.4 (c), and $(\mathbf{C}^{1/2})^2=\mathbf{C}$ gives

$$\tfrac{1}{2}(\mathbf{I}+\mathbf{C})-\mathbf{C}^{1/2}=\tfrac{1}{2}\big(\mathbf{I}-\mathbf{C}^{1/2}\big)^2\ \succeq\ 0.$$

Conjugating by $\mathbf{A}^{1/2}$ and using $\mathbf{A}^{1/2}\mathbf{C}\mathbf{A}^{1/2}=\mathbf{B}$,

$$\tfrac{1}{2}(\mathbf{A}+\mathbf{B})-\mathbf{A}\#\mathbf{B}=\tfrac{1}{2}\mathbf{A}^{1/2}\big(\mathbf{I}-\mathbf{C}^{1/2}\big)^2\mathbf{A}^{1/2}\ \succeq\ 0,$$

by Proposition 12.1.2 (a). For the inversion formula, $\mathbf{A}\#\mathbf{B}=\mathbf{A}^{1/2}\mathbf{C}^{1/2}\mathbf{A}^{1/2}$ is a product of invertible matrices, with inverse $\mathbf{A}^{-1/2}\mathbf{C}^{-1/2}\mathbf{A}^{-1/2}$, where $\mathbf{C}^{-1/2}=(\mathbf{C}^{1/2})^{-1}$. On the other side, using $(\mathbf{A}^{-1})^{1/2}=\mathbf{A}^{-1/2}$ and $(\mathbf{A}^{-1})^{-1/2}=\mathbf{A}^{1/2}$,

$$\mathbf{A}^{-1}\#\mathbf{B}^{-1}=\mathbf{A}^{-1/2}\big(\mathbf{A}^{1/2}\mathbf{B}^{-1}\mathbf{A}^{1/2}\big)^{1/2}\mathbf{A}^{-1/2},$$

and $\mathbf{A}^{1/2}\mathbf{B}^{-1}\mathbf{A}^{1/2}=(\mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2})^{-1}=\mathbf{C}^{-1}$, whose positive square root is $\mathbf{C}^{-1/2}$, since $(\mathbf{C}^{-1/2})^2=\mathbf{C}^{-1}$ and $\mathbf{C}^{-1/2}\succ 0$. So $\mathbf{A}^{-1}\#\mathbf{B}^{-1}=\mathbf{A}^{-1/2}\mathbf{C}^{-1/2}\mathbf{A}^{-1/2}=(\mathbf{A}\#\mathbf{B})^{-1}$.

■

Part (a) is the statement to remember, because it is the one with no square roots in it: $\mathbf{A}\#\mathbf{B}$ is the best Hermitian matrix that can sit in the off-diagonal corner above $\mathbf{A}$ and $\mathbf{B}$. Read beside Lemma 20.11.1, which says that such a corner cannot be too large in singular value, part (a) says exactly how large it can be in the Loewner order.

Quick check. Take $\mathbf{B}=\mathbf{A}$. Part (a) then says that $\mathbf{A}$ is the largest Hermitian $\mathbf{X}$ with $\left(\begin{smallmatrix}\mathbf{A} & \mathbf{X}\\ \mathbf{X} & \mathbf{A}\end{smallmatrix}\right)\succeq 0$. Check by hand that $\mathbf{X}=\mathbf{A}$ is admissible and that $\mathbf{X}=2\mathbf{A}$ is not.

Solution. For $\mathbf{X}=\mathbf{A}$ the quadratic form at $(\mathbf{y}_1,\mathbf{y}_2)$ is

$$\mathbf{y}_1^*\mathbf{A}\mathbf{y}_1+\mathbf{y}_1^*\mathbf{A}\mathbf{y}_2+\mathbf{y}_2^*\mathbf{A}\mathbf{y}_1+\mathbf{y}_2^*\mathbf{A}\mathbf{y}_2=(\mathbf{y}_1+\mathbf{y}_2)^*\mathbf{A}(\mathbf{y}_1+\mathbf{y}_2)\ \ge\ 0,$$

so $\mathbf{X}=\mathbf{A}$ is admissible — as it must be, since $\mathbf{A}\#\mathbf{A}=\mathbf{A}$ by the second example after Definition 20.11.1. For $\mathbf{X}=2\mathbf{A}$ take $\mathbf{y}_2=-\mathbf{y}_1$: the four terms give $\mathbf{y}_1^*\mathbf{A}\mathbf{y}_1-4\mathbf{y}_1^*\mathbf{A}\mathbf{y}_1+\mathbf{y}_1^*\mathbf{A}\mathbf{y}_1=-2\mathbf{y}_1^*\mathbf{A}\mathbf{y}_1$, which is <0 for $\mathbf{y}_1\neq\mathbf{0}$ because $\mathbf{A}\succ 0$. So $2\mathbf{A}$ is not admissible.

20.11.6 The chain of three means

Beside the arithmetic mean $\frac{1}{2}(\mathbf{A}+\mathbf{B})$ and the geometric mean $\mathbf{A}\#\mathbf{B}$ sits a third. The **harmonic mean** of two positive definite matrices is the inverse of the arithmetic mean of their inverses,

$$\left(\frac{\mathbf{A}^{-1}+\mathbf{B}^{-1}}{2}\right)^{-1},$$

which at $n=1$ is the familiar $2ab/(a+b)$. For two positive numbers the three are ordered harmonic $\le$ geometric $\le$ arithmetic, and the same order holds for matrices.

Corollary 20.11.5 — Harmonic, Geometric and Arithmetic

Let $\mathbf{A},\mathbf{B}\in M_n(F)$ be positive definite. Then

$$\left(\frac{\mathbf{A}^{-1}+\mathbf{B}^{-1}}{2}\right)^{-1} \preceq \mathbf{A}\#\mathbf{B} \preceq \frac{\mathbf{A}+\mathbf{B}}{2}.$$

Proof. The right inequality is Theorem 20.11.4 (e). For the left, apply that same part to the positive definite matrices $\mathbf{A}^{-1}$ and $\mathbf{B}^{-1}$:

$$\mathbf{A}^{-1}\#\mathbf{B}^{-1} \preceq \tfrac{1}{2}(\mathbf{A}^{-1}+\mathbf{B}^{-1}).$$

Both sides are positive definite — the left by the remark after Definition 20.11.1, the right as a positive combination of positive definite matrices. Since $t\mapsto -1/t$ is operator monotone on $(0,\infty)$ (Proposition 16.11.3), applying it reverses the inequality between the inverses:

$$\left(\tfrac{1}{2}(\mathbf{A}^{-1}+\mathbf{B}^{-1})\right)^{-1} \preceq (\mathbf{A}^{-1}\#\mathbf{B}^{-1})^{-1}.$$

By Theorem 20.11.4 (e) the right side is $\mathbf{A}\#\mathbf{B}$.

■

The three means agree when $\mathbf{A}=\mathbf{B}$, and for the pair of the worked example they are

$$\tfrac{1}{5}\begin{pmatrix}28&26\\26&37\end{pmatrix} \preceq \begin{pmatrix}6&6\\6&9\end{pmatrix} \preceq \begin{pmatrix}\frac{13}{2}&7\\7&11\end{pmatrix},$$

the two differences being $\frac{2}{5}\left(\begin{smallmatrix}1&2\\2&4\end{smallmatrix}\right)$ and $\frac{1}{2}\left(\begin{smallmatrix}1&2\\2&4\end{smallmatrix}\right)$, each a non-negative multiple of a rank-one positive semidefinite matrix.

Remark. The geometric mean is the first genuinely non-commutative *average* in the book, and it is built out of two order facts proved long before this chapter: the operator monotonicity of $t\mapsto t^{1/2}$, which is Chapter 12 §05's Proposition 12.5.4, used in the claim inside Theorem 20.11.4, and the operator monotonicity of $t\mapsto -1/t$, which is Chapter 16 §11's Proposition 16.11.3, used in Corollary 20.11.5. Without the first, the extremal characterization would fail; without the second, the chain would have no left-hand end.

20.11.7 Exercises

20.11.7.1 A. Check your understanding

Exercise A1.

(a) Define $\mathbf{A}\#\mathbf{B}$ for positive definite $\mathbf{A}, \mathbf{B}$, and say why each square root in the formula exists.

(b) State the extremal characterization of $\mathbf{A}\#\mathbf{B}$, and explain in one sentence how it makes the symmetry $\mathbf{A}\#\mathbf{B} = \mathbf{B}\#\mathbf{A}$ obvious.

(c) Decide whether the following is correct, and justify your answer: "$\mathbf{A}^{1/2}\mathbf{B}^{1/2}$ is positive definite whenever $\mathbf{A}$ and $\mathbf{B}$ are".

(d) State the matrix Cauchy–Schwarz inequality and the arithmetic–geometric mean inequality for singular values, Theorem 20.11.2 — not the one for the geometric mean $\mathbf{A}\#\mathbf{B}$ — and say which one implies the other and how.

(e) Which of $\mathbf{A}^*\mathbf{A} + \mathbf{B}^*\mathbf{B}$ and $\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*$ bounds $2\,|||\mathbf{A}^*\mathbf{B}|||$, and what goes wrong with the other?

Solution.

(a) $\mathbf{A}\#\mathbf{B} = \mathbf{A}^{1/2}(\mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2})^{1/2}\mathbf{A}^{1/2}$ (Definition 20.11.1). The outer square root exists because $\mathbf{A} \succ 0$ (Theorem 12.2.1), and $\mathbf{A}^{1/2} \succ 0$ is invertible; the inner one because $\mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2}$ is a congruence of $\mathbf{B} \succ 0$ by an invertible matrix, hence $\succ 0$ (Proposition 12.1.2 (b)).

(b) It is the largest Hermitian $\mathbf{X}$ with $\left(\begin{smallmatrix}\mathbf{A} & \mathbf{X}\\ \mathbf{X} & \mathbf{B}\end{smallmatrix}\right) \succeq 0$ (Theorem 20.11.4 (a)). Swapping the two diagonal blocks is a congruence by the unitary $\left(\begin{smallmatrix}\mathbf{0} & \mathbf{I}\\ \mathbf{I} & \mathbf{0}\end{smallmatrix}\right)$, which changes neither the condition nor $\mathbf{X}$, so $(\mathbf{A}, \mathbf{B})$ and $(\mathbf{B}, \mathbf{A})$ have the same admissible set and therefore the same largest element.

(c) Incorrect. It need not even be Hermitian: with $\mathbf{A} = \operatorname{diag}(4, 1)$ and $\mathbf{B} = \left(\begin{smallmatrix}5 & 4\\ 4 & 5\end{smallmatrix}\right)$, $\mathbf{A}^{1/2}\mathbf{B}^{1/2} = \left(\begin{smallmatrix}4 & 2\\ 1 & 2\end{smallmatrix}\right)$. It is Hermitian exactly when $\mathbf{A}\mathbf{B} = \mathbf{B}\mathbf{A}$.

(d) Cauchy–Schwarz: $|||\mathbf{A}^*\mathbf{B}|||^2 \le |||\mathbf{A}^*\mathbf{A}|||\,|||\mathbf{B}^*\mathbf{B}|||$ (Theorem 20.11.3). Arithmetic–geometric mean for singular values: $2\,|||\mathbf{A}^*\mathbf{B}||| \le |||\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*|||$ (Theorem 20.11.2). The second implies the first: replace $\mathbf{A}$ by $t\mathbf{A}$ and $\mathbf{B}$ by $t^{-1}\mathbf{B}$, which leaves $\mathbf{A}^*\mathbf{B}$ alone, use the triangle inequality, and pick t to balance the two terms.

(e) $\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*$ does (Theorem 20.11.2). With $\mathbf{A}^*\mathbf{A} + \mathbf{B}^*\mathbf{B}$ the statement is false: the warning after that theorem gives $\mathbf{A}, \mathbf{B}$ with $\mathbf{A}^*\mathbf{A} + \mathbf{B}^*\mathbf{B} = \mathbf{I}$ of spectral norm 1 and $2\|\mathbf{A}^*\mathbf{B}\|_2 = 2$.

20.11.7.2 B. Practice

Exercise B1: A geometric mean, exactly.

Let

$$\mathbf{A} = \begin{pmatrix} 5 & 4 \\ 4 & 5 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 13 & 20 \\ 20 & 37 \end{pmatrix}.$$

(a) Verify that $\mathbf{A}^{1/2} = \left(\begin{smallmatrix}2 & 1\\ 1 & 2\end{smallmatrix}\right)$ and compute $\mathbf{C} = \mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2}$ and $\mathbf{A}\#\mathbf{B}$.

(b) Check the arithmetic–geometric mean inequality $\mathbf{A}\#\mathbf{B} \preceq \frac{1}{2}(\mathbf{A} + \mathbf{B})$ directly, by computing the difference and its eigenvalues.

(c) Verify the extremal characterization for your answer by computing the Schur complement $\mathbf{B} - \mathbf{X}\mathbf{A}^{-1}\mathbf{X}$ with $\mathbf{X} = \mathbf{A}\#\mathbf{B}$.

Solution.

(a) $\left(\begin{smallmatrix}2&1\\1&2\end{smallmatrix}\right)^2 = \left(\begin{smallmatrix}5&4\\4&5\end{smallmatrix}\right) = \mathbf{A}$, and $\left(\begin{smallmatrix}2&1\\1&2\end{smallmatrix}\right)$ has eigenvalues 3 and 1, both positive, so it is $\succ 0$ and is the positive square root (Theorem 12.2.1). Its determinant is 3, so $\mathbf{A}^{-1/2} = \frac{1}{3}\left(\begin{smallmatrix}2&-1\\-1&2\end{smallmatrix}\right)$. Then

$$\mathbf{A}^{-1/2}\mathbf{B} = \tfrac{1}{3}\begin{pmatrix}6&3\\27&54\end{pmatrix} = \begin{pmatrix}2&1\\9&18\end{pmatrix},$$

and multiplying on the right by $\mathbf{A}^{-1/2}$ gives $\mathbf{C} = \frac{1}{3}\left(\begin{smallmatrix}3&0\\0&27\end{smallmatrix}\right) = \operatorname{diag}(1,9)$. Hence $\mathbf{C}^{1/2} = \operatorname{diag}(1,3)$ and

$$\mathbf{A}\#\mathbf{B} = \begin{pmatrix}2&1\\1&2\end{pmatrix}\begin{pmatrix}1&0\\0&3\end{pmatrix}\begin{pmatrix}2&1\\1&2\end{pmatrix} = \begin{pmatrix}7&8\\8&13\end{pmatrix}.$$

(b) $\frac{1}{2}(\mathbf{A}+\mathbf{B}) = \left(\begin{smallmatrix}9&12\\12&21\end{smallmatrix}\right)$, so the difference is

$$\tfrac{1}{2}(\mathbf{A}+\mathbf{B}) - \mathbf{A}\#\mathbf{B} = \begin{pmatrix}2&4\\4&8\end{pmatrix} = 2\begin{pmatrix}1\\2\end{pmatrix}\begin{pmatrix}1&2\end{pmatrix},$$

of trace 10 and determinant $16-16=0$, so its eigenvalues are 10 and 0 and it is $\succeq 0$ (Theorem 12.1.4 (b)). The inequality holds, with the difference singular.

(c) $\det\mathbf{A} = 9$, so $\mathbf{A}^{-1} = \frac{1}{9}\left(\begin{smallmatrix}5&-4\\-4&5\end{smallmatrix}\right)$. With $\mathbf{X} = \left(\begin{smallmatrix}7&8\\8&13\end{smallmatrix}\right)$,

$$\mathbf{X}\mathbf{A}^{-1} = \tfrac{1}{9}\begin{pmatrix}3&12\\-12&33\end{pmatrix} = \tfrac{1}{3}\begin{pmatrix}1&4\\-4&11\end{pmatrix},$$

and $\mathbf{X}\mathbf{A}^{-1}\mathbf{X} = \frac{1}{3}\left(\begin{smallmatrix}39&60\\60&111\end{smallmatrix}\right) = \left(\begin{smallmatrix}13&20\\20&37\end{smallmatrix}\right) = \mathbf{B}$. So the Schur complement is $\mathbf{0}$, which is $\succeq 0$: $\mathbf{X}$ is admissible, and the block matrix is singular, as it must be at the largest admissible $\mathbf{X}$.

Exercise B2: The two inequalities on one pair.

Let $\mathbf{A} = \left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ and $\mathbf{B} = \left(\begin{smallmatrix}1&0\\1&1\end{smallmatrix}\right)$ in $M_2(\mathbb{R})$.

(a) Compute $\mathbf{A}^*\mathbf{B}$ and $\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*$, and verify $2\sigma_j(\mathbf{A}^*\mathbf{B}) \le \lambda_j(\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^*)$ for $j = 1, 2$ using traces and determinants.

(b) Verify Theorem 20.11.3 for this pair in the Frobenius norm.

Solution.

(a) $\mathbf{A}^* = \left(\begin{smallmatrix}1&0\\1&1\end{smallmatrix}\right)$, so $\mathbf{A}^*\mathbf{B} = \left(\begin{smallmatrix}1&0\\2&1\end{smallmatrix}\right)$, and $\mathbf{A}\mathbf{A}^* = \left(\begin{smallmatrix}2&1\\1&1\end{smallmatrix}\right)$, $\mathbf{B}\mathbf{B}^* = \left(\begin{smallmatrix}1&1\\1&2\end{smallmatrix}\right)$, so $\mathbf{A}\mathbf{A}^* + \mathbf{B}\mathbf{B}^* = \left(\begin{smallmatrix}3&2\\2&3\end{smallmatrix}\right)$, with eigenvalues 5 and 1.
The singular values of $\mathbf{M} = \mathbf{A}^*\mathbf{B}$ come from $\mathbf{M}^*\mathbf{M} = \left(\begin{smallmatrix}5&2\\2&1\end{smallmatrix}\right)$, of trace 6 and determinant 1, so $\sigma_1^2, \sigma_2^2 = 3 \pm 2\sqrt{2} = (\sqrt{2}\pm 1)^2$ and $\sigma_1 = \sqrt{2}+1$, $\sigma_2 = \sqrt{2}-1$. Then $2\sigma_1 = 2\sqrt{2}+2 \approx 4.83 \le 5$ and $2\sigma_2 = 2\sqrt{2}-2 \approx 0.83 \le 1$. Both hold; the first is $2\sqrt{2} \le 3$, that is $8 \le 9$, and the second is $2\sqrt{2} \le 3$ again.

(b) $\mathbf{A}^*\mathbf{A} = \left(\begin{smallmatrix}1&1\\1&2\end{smallmatrix}\right)$ and $\mathbf{B}^*\mathbf{B} = \left(\begin{smallmatrix}2&1\\1&1\end{smallmatrix}\right)$, each of Frobenius norm $\sqrt{1+1+1+4} = \sqrt{7}$. And $\|\mathbf{A}^*\mathbf{B}\|_F^2 = 1+4+1 = 6$. So the inequality reads $6 \le \sqrt{7}\cdot\sqrt{7} = 7$, which holds.

Exercise B3: Means of commuting matrices.

Let $\mathbf{A} = \operatorname{diag}(a_1, \dots, a_n)$ and $\mathbf{B} = \operatorname{diag}(b_1, \dots, b_n)$ with all $a_i, b_i > 0$. Compute the three means of Corollary 20.11.5 and deduce the classical chain of inequalities between the harmonic, geometric and arithmetic means of two positive numbers.

Solution. The matrices commute, so $\mathbf{A}\#\mathbf{B} = (\mathbf{AB})^{1/2} = \operatorname{diag}(\sqrt{a_i b_i})$ by the third example after Definition 20.11.1. Also $\frac{1}{2}(\mathbf{A}+\mathbf{B}) = \operatorname{diag}\big(\frac{a_i+b_i}{2}\big)$ and

$$\Big(\frac{\mathbf{A}^{-1}+\mathbf{B}^{-1}}{2}\Big)^{-1} = \operatorname{diag}\Big(\frac{2a_ib_i}{a_i+b_i}\Big).$$

A diagonal matrix is $\succeq 0$ exactly when its entries are ≥ 0, so Corollary 20.11.5 says precisely

$$\frac{2a_ib_i}{a_i+b_i} \;\leq\; \sqrt{a_ib_i} \;\leq\; \frac{a_i+b_i}{2}$$

for every i, the classical chain for the two positive numbers a_i, b_i. The right inequality is Lemma 16.8.6 with two terms, and the left is the right one applied to $1/a_i$ and $1/b_i$ and inverted.

20.11.7.3 C. Going deeper

Exercise C1: The determinant of a geometric mean.

Let $\mathbf{A}, \mathbf{B} \in M_n(F)$ be positive definite.

(a) Prove that $\det(\mathbf{A}\#\mathbf{B}) = \sqrt{\det \mathbf{A}\, \det \mathbf{B}}$.

(b) Deduce from Corollary 20.11.5 that $\sqrt{\det \mathbf{A}\, \det \mathbf{B}} \leq \det\big(\frac{1}{2}(\mathbf{A}+\mathbf{B})\big)$.

Hint for (b): the Loewner order compares determinants of positive definite matrices.

Solution.

(a) Write $\mathbf{C} = \mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2}$. Taking determinants in Definition 20.11.1 and using multiplicativity (Theorem 6.5.4),

$$\det(\mathbf{A}\#\mathbf{B}) = \det(\mathbf{A}^{1/2})^2 \det(\mathbf{C}^{1/2}) = \det \mathbf{A} \cdot \det(\mathbf{C}^{1/2}).$$

Now $(\mathbf{C}^{1/2})^2 = \mathbf{C}$ gives $\det(\mathbf{C}^{1/2})^2 = \det \mathbf{C}$, and $\det(\mathbf{C}^{1/2}) > 0$ because $\mathbf{C}^{1/2} \succ 0$ has positive eigenvalues, so $\det(\mathbf{C}^{1/2}) = \sqrt{\det \mathbf{C}}$. Finally $\det \mathbf{C} = \det(\mathbf{A}^{-1/2})^2 \det \mathbf{B} = \det \mathbf{B}/\det \mathbf{A}$. Hence

$$\det(\mathbf{A}\#\mathbf{B}) = \det \mathbf{A} \cdot \sqrt{\det \mathbf{B}/\det \mathbf{A}} = \sqrt{\det \mathbf{A}\, \det \mathbf{B}}.$$

(b) By Corollary 20.11.5, $\mathbf{A}\#\mathbf{B} \preceq \frac{1}{2}(\mathbf{A}+\mathbf{B})$, and both are positive definite. For positive definite $\mathbf{X} \preceq \mathbf{Y}$ we have $\det \mathbf{X} \leq \det \mathbf{Y}$: by Corollary 16.2.4, $\lambda_i(\mathbf{Y}) \geq \lambda_i(\mathbf{X}) > 0$ for every i, and the determinant of a Hermitian matrix is the product of its eigenvalues with multiplicity (Theorem 8.3.3, whose hypothesis holds because the characteristic polynomial of a Hermitian matrix splits over $\mathbb{R}$ by Theorem 11.2.1), a product of positive numbers increasing in each factor. Applying this and part

(a) gives the inequality. At $n = 1$ it is again the classical arithmetic–geometric mean inequality.

Exercise C2: The geometric mean solves an equation.

Let $\mathbf{A}, \mathbf{B} \in M_n(F)$ be positive definite.

(a) Prove that $\mathbf{X} = \mathbf{A}\#\mathbf{B}$ is the **only** positive definite solution of $\mathbf{X}\mathbf{A}^{-1}\mathbf{X} = \mathbf{B}$.

(b) Use (a) to give a second proof that $\mathbf{A}\#\mathbf{B} = \mathbf{B}\#\mathbf{A}$.

Solution.

(a) Write $\mathbf{C} = \mathbf{A}^{-1/2}\mathbf{B}\mathbf{A}^{-1/2}$. A positive definite $\mathbf{X}$ may be written uniquely as $\mathbf{X} = \mathbf{A}^{1/2}\mathbf{Y}\mathbf{A}^{1/2}$ with $\mathbf{Y} = \mathbf{A}^{-1/2}\mathbf{X}\mathbf{A}^{-1/2}$, and $\mathbf{Y} \succ 0$ by Proposition 12.1.2 (b). As computed in the proof of Theorem 20.11.4 (a), $\mathbf{X}\mathbf{A}^{-1}\mathbf{X} = \mathbf{A}^{1/2}\mathbf{Y}^2\mathbf{A}^{1/2}$. So $\mathbf{X}\mathbf{A}^{-1}\mathbf{X} = \mathbf{B}$ is equivalent to $\mathbf{A}^{1/2}\mathbf{Y}^2\mathbf{A}^{1/2} = \mathbf{A}^{1/2}\mathbf{C}\mathbf{A}^{1/2}$, that is to $\mathbf{Y}^2 = \mathbf{C}$, since $\mathbf{A}^{1/2}$ is invertible. By the uniqueness of the positive square root (Theorem 12.2.1), the only positive definite solution is $\mathbf{Y} = \mathbf{C}^{1/2}$, that is $\mathbf{X} = \mathbf{A}\#\mathbf{B}$.

(b) Let $\mathbf{X} = \mathbf{A}\#\mathbf{B}$, so $\mathbf{X}\mathbf{A}^{-1}\mathbf{X} = \mathbf{B}$ by (a) and $\mathbf{X} \succ 0$ is invertible. Multiplying that identity on the left and on the right by $\mathbf{X}^{-1}$ gives $\mathbf{A}^{-1} = \mathbf{X}^{-1}\mathbf{B}\mathbf{X}^{-1}$, and inverting both sides gives $\mathbf{A} = \mathbf{X}\mathbf{B}^{-1}\mathbf{X}$. So $\mathbf{X}$ is a positive definite solution of $\mathbf{X}\mathbf{B}^{-1}\mathbf{X} = \mathbf{A}$, which by (a), with the roles of $\mathbf{A}$ and $\mathbf{B}$ exchanged, has $\mathbf{B}\#\mathbf{A}$ as its only positive definite solution. Hence $\mathbf{A}\#\mathbf{B} = \mathbf{B}\#\mathbf{A}$.

Exercise C3: Cauchy–Schwarz for the Ky Fan norms, directly.

Let $\mathbf{A}, \mathbf{B} \in M_n(F)$ and $1 \le k \le n$.

(a) Let $\mathbf{A}^*\mathbf{B} = \mathbf{W}\mathbf{\Sigma}\mathbf{Z}^*$ be a singular value decomposition (Theorem 12.8.1), and let $\mathbf{U}_k$ and $\mathbf{V}_k$ be the matrices of the first k columns of $\mathbf{W}$ and of $\mathbf{Z}$. Show that $\operatorname{tr}(\mathbf{U}_k^*\mathbf{A}^*\mathbf{B}\mathbf{V}_k) = \sum_{j\le k}\sigma_j(\mathbf{A}^*\mathbf{B})$.

(b) Deduce, using the Cauchy–Schwarz inequality for the Frobenius inner product (Theorem 10.1.5) and the Ky Fan maximum principle (Theorem 16.6.2), that

$$\sum_{j\le k}\sigma_j(\mathbf{A}^*\mathbf{B}) \le \Big(\sum_{j\le k}\lambda_j(\mathbf{A}^*\mathbf{A})\Big)^{1/2}\Big(\sum_{j\le k}\lambda_j(\mathbf{B}^*\mathbf{B})\Big)^{1/2}.$$

Solution.

(a) The columns of $\mathbf{W}$ and $\mathbf{Z}$ are orthonormal, so $\mathbf{U}_k^*\mathbf{W} = (\mathbf{I}_k \;\; \mathbf{0})$ and $\mathbf{Z}^*\mathbf{V}_k = \left(\begin{smallmatrix}\mathbf{I}_k\\ \mathbf{0}\end{smallmatrix}\right)$. Hence

$$\mathbf{U}_k^*\mathbf{A}^*\mathbf{B}\mathbf{V}_k = \mathbf{U}_k^*\mathbf{W}\mathbf{\Sigma}\mathbf{Z}^*\mathbf{V}_k = \operatorname{diag}\big(\sigma_1, \dots, \sigma_k\big),$$

the top-left $k \times k$ corner of $\mathbf{\Sigma}$, whose trace is $\sum_{j\le k}\sigma_j(\mathbf{A}^*\mathbf{B})$.

(b) Writing the trace as the Frobenius inner product $\langle \mathbf{X}, \mathbf{Y}\rangle = \operatorname{tr}(\mathbf{Y}^*\mathbf{X})$ of Chapter 10 §01,

$$\operatorname{tr}\big(\mathbf{U}_k^*\mathbf{A}^*\mathbf{B}\mathbf{V}_k\big) = \operatorname{tr}\big((\mathbf{A}\mathbf{U}_k)^*(\mathbf{B}\mathbf{V}_k)\big) = \langle \mathbf{B}\mathbf{V}_k, \mathbf{A}\mathbf{U}_k\rangle,$$

so by Theorem 10.1.5 it is at most $\|\mathbf{A}\mathbf{U}_k\|_F\|\mathbf{B}\mathbf{V}_k\|_F$. Now $\mathbf{U}_k^*\mathbf{U}_k = \mathbf{I}_k$, so $\mathbf{U}_k$ is

an isometry and

$$\|\mathbf{A}\mathbf{U}_k\|_F^2 = \operatorname{tr}\big(\mathbf{U}_k^{*}\mathbf{A}^{*}\mathbf{A}\mathbf{U}_k\big) \;\le\; \sum_{j\le k}\lambda_j(\mathbf{A}^{*}\mathbf{A})$$

by Theorem 16.6.2 applied to the Hermitian matrix $\mathbf{A}^{*}\mathbf{A}$. The same bound holds for $\|\mathbf{B}\mathbf{V}_k\|_F^2$ with $\mathbf{B}^{*}\mathbf{B}$. Combining with (a) gives the display. (Taking $k = n$ recovers Theorem 20.11.3 for the trace norm.)

20.12 Golden–Thompson

For numbers, $e^{a+b} = e^a e^b$. For matrices this fails the moment $\mathbf{A}$ and $\mathbf{B}$ stop commuting, and Chapter 9 §09 was careful to say so: Theorem 9.9.4 (d) buys the identity only at the price of $\mathbf{AB} = \mathbf{BA}$. The question this section answers is what survives without that price. The answer is that the **trace** still knows the right inequality, in one direction, and that the direction is the useful one.

The section also closes the chapter, and Part V with it. After Golden–Thompson come two of its relatives — Klein's inequality and the non-negativity of the relative entropy — a counterexample showing that three matrices are one too many, and one theorem that is quoted rather than proved.

20.12.1 Sums in the exponent, products in the answer

A product $e^{\mathbf{A}}e^{\mathbf{B}}$ is not $e^{\mathbf{A}+\mathbf{B}}$, but it is not far off either: to first order in $\mathbf{A}$ and $\mathbf{B}$ the two agree, since both are $\mathbf{I}+\mathbf{A}+\mathbf{B}+\dots$, and the discrepancy is quadratic. So if the exponents are made small by a factor $1/k$ and the resulting error is repaired k times over, the discrepancy should vanish. It does, and this is the one tool that turns a sum in the exponent into a product.

Lemma 20.12.1 — Lie's Product Formula

Let $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$. Then

$$e^{\mathbf{A}+\mathbf{B}} = \lim_{k\to\infty}\big(e^{\mathbf{A}/k}e^{\mathbf{B}/k}\big)^k,$$

the limit taken entrywise, and also in any norm on $M_n(\mathbb{C})$.

Idea. Write $\mathbf{S}_k = e^{(\mathbf{A}+\mathbf{B})/k}$ and $\mathbf{T}_k = e^{\mathbf{A}/k}e^{\mathbf{B}/k}$. Then $\mathbf{S}_k^k$ is exactly $e^{\mathbf{A}+\mathbf{B}}$, so the whole task is to compare $\mathbf{S}_k^k$ with $\mathbf{T}_k^k$. Two estimates do it. Both $\mathbf{S}_k$ and $\mathbf{T}_k$ have norm at most $e^{(\|\mathbf{A}\|+\|\mathbf{B}\|)/k}$, so no power of either can be large; and $\mathbf{S}_k - \mathbf{T}_k$ is of size $1/k^2$, because the two agree through the linear term. A telescoping identity turns a difference of k-th powers into k copies of $\mathbf{S}_k - \mathbf{T}_k$, and $k \cdot 1/k^2$ tends to 0.

Proof. Fix the spectral norm $\|\cdot\|_2$, which is submultiplicative by Theorem 15.3.2 (d). Put $a = \|\mathbf{A}\|_2$, $b = \|\mathbf{B}\|_2$ and $c = a + b$, and let k be an integer with $k \ge \max(1, c)$.

Write

$$\mathbf{S}_k = e^{(\mathbf{A}+\mathbf{B})/k}, \qquad \mathbf{T}_k = e^{\mathbf{A}/k}e^{\mathbf{B}/k}.$$

Step 1. $\mathbf{S}_k^k = e^{\mathbf{A}+\mathbf{B}}$. The matrix $(\mathbf{A}+\mathbf{B})/k$ commutes with itself, so Theorem 9.9.4 (d) gives $e^{j(\mathbf{A}+\mathbf{B})/k}e^{(\mathbf{A}+\mathbf{B})/k} = e^{(j+1)(\mathbf{A}+\mathbf{B})/k}$ for every $j \geq 0$. Induction on j yields $\mathbf{S}_k^j = e^{j(\mathbf{A}+\mathbf{B})/k}$, and $j = k$ is the claim.

Step 2. Norm bounds. By Theorem 15.6.1 (a), $\|\mathbf{S}_k\|_2 \leq e^{\|\mathbf{A}+\mathbf{B}\|_2/k} \leq e^{c/k}$, using $\|\mathbf{A}+\mathbf{B}\|_2 \leq c$; and $\|\mathbf{T}_k\|_2 \leq e^{a/k}e^{b/k} = e^{c/k}$ by submultiplicativity. Since $k \geq c$, both are at most e.

Step 3. $\mathbf{S}_k - \mathbf{T}_k$ is of size $1/k^2$. For any $\mathbf{X} \in M_n(\mathbb{C})$ put $\mathbf{R}(\mathbf{X}) = e^{\mathbf{X}} - \mathbf{I} - \mathbf{X}$, so that Theorem 15.6.1 (c) gives

$$\|\mathbf{R}(\mathbf{X})\|_2 \leq \tfrac{1}{2}\|\mathbf{X}\|_2^2\, e^{\|\mathbf{X}\|_2}.$$

Multiplying out $\mathbf{T}_k = \big(\mathbf{I} + \frac{\mathbf{A}}{k} + \mathbf{R}(\frac{\mathbf{A}}{k})\big)\big(\mathbf{I} + \frac{\mathbf{B}}{k} + \mathbf{R}(\frac{\mathbf{B}}{k})\big)$, and using $e^{\mathbf{B}/k} = \mathbf{I} + \frac{\mathbf{B}}{k} + \mathbf{R}(\frac{\mathbf{B}}{k})$ to collect the three terms that begin with $\mathbf{R}(\frac{\mathbf{A}}{k})$,

$$\mathbf{T}_k = \mathbf{I} + \frac{\mathbf{A}+\mathbf{B}}{k} + \mathbf{R}\Big(\frac{\mathbf{B}}{k}\Big) + \frac{\mathbf{A}\mathbf{B}}{k^2} + \frac{\mathbf{A}}{k}\mathbf{R}\Big(\frac{\mathbf{B}}{k}\Big) + \mathbf{R}\Big(\frac{\mathbf{A}}{k}\Big)e^{\mathbf{B}/k}.$$

Subtracting this from $\mathbf{S}_k = \mathbf{I} + \frac{\mathbf{A}+\mathbf{B}}{k} + \mathbf{R}\big(\frac{\mathbf{A}+\mathbf{B}}{k}\big)$, the constant and linear terms cancel, and the triangle inequality with $a/k, b/k, c/k \leq 1$ gives

$$\begin{aligned}\|\mathbf{S}_k - \mathbf{T}_k\|_2 &\leq \frac{c^2 e}{2k^2} + \frac{b^2 e}{2k^2} + \frac{ab}{k^2} + \frac{ab^2 e}{2k^3} + \frac{a^2 e^2}{2k^2} \\ &\leq \frac{M}{k^2}, \qquad M = \frac{(c^2+b^2)e}{2} + ab + \frac{ab^2 e}{2} + \frac{a^2 e^2}{2},\end{aligned}$$

where the fourth term used $1/k^3 \leq 1/k^2$. The constant M depends only on $\mathbf{A}$ and $\mathbf{B}$.

Step 4. Telescoping. For any $\mathbf{M}, \mathbf{N} \in M_n(\mathbb{C})$ and any $k \geq 1$,

$$\mathbf{M}^k - \mathbf{N}^k = \sum_{j=0}^{k-1} \mathbf{M}^j(\mathbf{M}-\mathbf{N})\mathbf{N}^{k-1-j},$$

since the j-th summand is $\mathbf{M}^{j+1}\mathbf{N}^{k-1-j} - \mathbf{M}^j\mathbf{N}^{k-j}$ and the sum telescopes. Applying this to $\mathbf{M} = \mathbf{S}_k$, $\mathbf{N} = \mathbf{T}_k$ and using Steps 1 and 2,

$$\|e^{\mathbf{A}+\mathbf{B}} - \mathbf{T}_k^k\|_2 \leq \sum_{j=0}^{k-1} e^{jc/k}\,\|\mathbf{S}_k - \mathbf{T}_k\|_2\, e^{(k-1-j)c/k} \leq k\, e^{c}\,\frac{M}{k^2} = \frac{e^c M}{k}.$$

The right side tends to 0, so $\mathbf{T}_k^k \to e^{\mathbf{A}+\mathbf{B}}$ in the spectral norm, hence entrywise and in every norm by Corollary 15.2.4. This proves the formula.

■

Nothing in the proof used that the matrices are Hermitian: the formula holds for all complex matrices. What it costs is a limit, and every consequence below is obtained by pushing an inequality through that limit.

20.12.2 The trace of a product of two positive matrices

Golden–Thompson compares $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}}$ with $\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}})$. Before comparing them we should know that the second number is real, which is not obvious: the product of two Hermitian matrices is almost never Hermitian. One identity settles this, and it will be used again.

Lemma 20.12.2 — Powers of a Product of Two Positive Matrices

Let $\mathbf{X}, \mathbf{Y} \in M_n(\mathbb{C})$ be positive semidefinite and let $k \geq 1$. Then

$$\operatorname{tr}\big((\mathbf{X}\mathbf{Y})^k\big) = \operatorname{tr}\big((\mathbf{X}^{1/2}\mathbf{Y}\mathbf{X}^{1/2})^k\big),$$

and this number is real and ≥ 0.

Proof. Let $\mathbf{X}^{1/2}$ be the positive square root of Theorem 12.2.1, and put $\mathbf{S} = \mathbf{X}^{1/2}\mathbf{Y}\mathbf{X}^{1/2}$. We claim

$$(\mathbf{X}\mathbf{Y})^k = \mathbf{X}^{1/2}\,\mathbf{S}^{k-1}\,\mathbf{X}^{1/2}\mathbf{Y} \qquad (k \geq 1).$$

For $k = 1$ the right side is $\mathbf{X}^{1/2}\mathbf{X}^{1/2}\mathbf{Y} = \mathbf{X}\mathbf{Y}$. Assuming it for k, and using $\mathbf{X}^{1/2}\mathbf{Y}\mathbf{X}\mathbf{Y} = \mathbf{S}\,\mathbf{X}^{1/2}\mathbf{Y}$,

$$(\mathbf{X}\mathbf{Y})^{k+1} = \mathbf{X}^{1/2}\mathbf{S}^{k-1}\big(\mathbf{X}^{1/2}\mathbf{Y}\mathbf{X}\mathbf{Y}\big) = \mathbf{X}^{1/2}\mathbf{S}^{k}\mathbf{X}^{1/2}\mathbf{Y},$$

which is the claim for $k+1$. Taking traces and moving the leading $\mathbf{X}^{1/2}$ to the back, which Theorem 0.9.6 (3) permits,

$$\operatorname{tr}\big((\mathbf{X}\mathbf{Y})^k\big) = \operatorname{tr}\big(\mathbf{S}^{k-1}\mathbf{X}^{1/2}\mathbf{Y}\mathbf{X}^{1/2}\big) = \operatorname{tr}(\mathbf{S}^{k}).$$

Now $\mathbf{S} = (\mathbf{X}^{1/2})^{*}\mathbf{Y}\mathbf{X}^{1/2} \succeq 0$ by Proposition 12.1.2 (a), since $\mathbf{X}^{1/2}$ is Hermitian. So $\mathbf{S}^k$ is Hermitian with eigenvalues the k-th powers of those of $\mathbf{S}$, all ≥ 0 by Theorem 12.1.4 (b). Its trace is the sum of its eigenvalues (Theorem 8.3.3), hence real and ≥ 0. ∎

Quick check. Why is $\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}})$ a real number for Hermitian $\mathbf{A}$ and $\mathbf{B}$, even though $e^{\mathbf{A}}e^{\mathbf{B}}$ is not Hermitian?

Solution. For Hermitian $\mathbf{A}$ with spectral resolution $\mathbf{A} = \sum_i \lambda_i \mathbf{P}_i$, Theorem 11.8.5 (a) gives $e^{\mathbf{A}} = \sum_i e^{\lambda_i}\mathbf{P}_i$, which is Hermitian with positive eigenvalues, hence positive definite by Theorem 12.1.4 (b). The same holds for $e^{\mathbf{B}}$. So Lemma 20.12.2 with $k = 1$ applies: $\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}})$ is real and ≥ 0. The product itself is not Hermitian unless $\mathbf{A}$ and $\mathbf{B}$ commute, but its trace does not notice.

The engine of Golden–Thompson is the next inequality. It says that in a trace, the powers may be moved off the product and onto the two factors — provided the exponent is a power of two. That restriction is not an accident of the proof technique here; it is what makes a repeated Cauchy–Schwarz argument close.

Lemma 20.12.3 — The Trace Power Inequality

Let $r \geq 0$ and $m = 2^r$.

(a) $\operatorname{tr}\big((\mathbf{A}^*)^m \mathbf{A}^m\big) \leq \operatorname{tr}\big((\mathbf{A}\mathbf{A}^*)^m\big)$ for every $\mathbf{A} \in M_n(\mathbb{C})$.
(b) $\operatorname{tr}\big((\mathbf{X}\mathbf{Y})^m\big) \leq \operatorname{tr}\big(\mathbf{X}^m \mathbf{Y}^m\big)$ for all positive semidefinite $\mathbf{X}, \mathbf{Y} \in M_n(\mathbb{C})$.

Idea. Both halves are proved together by induction on r, because each step of one needs the other at the previous stage. The only inequality used is Cauchy–Schwarz for the Frobenius inner product, in the form $|\operatorname{tr}(\mathbf{M}^2)| \leq \operatorname{tr}(\mathbf{M}^*\mathbf{M})$: a trace of a square is bounded by a trace of a product of a matrix with its adjoint. Everything else is cyclic rearrangement of words in $\mathbf{X}$ and $\mathbf{Y}$, or in $\mathbf{A}$ and $\mathbf{A}^*$. The role of (a) is to absorb the mismatch that Cauchy–Schwarz creates: it turns $(\mathbf{A}^*)^m \mathbf{A}^m$ — the wrong grouping — into $(\mathbf{A}\mathbf{A}^*)^m$, which is a word one can feed back into (b).

Proof. Throughout, $\langle \mathbf{M}, \mathbf{N} \rangle = \operatorname{tr}(\mathbf{N}^*\mathbf{M})$ is the Frobenius inner product of Chapter 10 §01, with induced norm $\|\mathbf{M}\|_F$.

Claim 1. $|\operatorname{tr}(\mathbf{M}^2)| \leq \operatorname{tr}(\mathbf{M}^*\mathbf{M})$ *for every* $\mathbf{M} \in M_n(\mathbb{C})$. Since $(\mathbf{M}^*)^* = \mathbf{M}$, we have $\operatorname{tr}(\mathbf{M}^2) = \operatorname{tr}\big((\mathbf{M}^*)^*\mathbf{M}\big) = \langle \mathbf{M}, \mathbf{M}^* \rangle$. By Theorem 10.1.5, $|\langle \mathbf{M}, \mathbf{M}^* \rangle| \leq \|\mathbf{M}\|_F \|\mathbf{M}^*\|_F$. Finally $\|\mathbf{M}^*\|_F^2 = \operatorname{tr}(\mathbf{M}\mathbf{M}^*) = \operatorname{tr}(\mathbf{M}^*\mathbf{M}) = \|\mathbf{M}\|_F^2$ by Theorem 0.9.6 (3), so the bound is $\|\mathbf{M}\|_F^2 = \operatorname{tr}(\mathbf{M}^*\mathbf{M})$.

Claim 2. *For positive semidefinite* $\mathbf{X}, \mathbf{Y}$ *and* $q \geq 1$, $\operatorname{tr}\big((\mathbf{X}\mathbf{Y}^2\mathbf{X})^q\big) = \operatorname{tr}\big((\mathbf{X}^2\mathbf{Y}^2)^q\big)$*; and for any* $\mathbf{A}$ *and* $q \geq 1$, $\operatorname{tr}\big((\mathbf{A}^2(\mathbf{A}^*)^2)^q\big) = \operatorname{tr}\big((\mathbf{P}\mathbf{Q})^q\big)$*, where* $\mathbf{P} = \mathbf{A}\mathbf{A}^*$ *and* $\mathbf{Q} = \mathbf{A}^*\mathbf{A}$. Both are cyclic rearrangements, justified by Theorem 0.9.6 (3). Induction on q gives $(\mathbf{X}\mathbf{Y}^2\mathbf{X})^q = \mathbf{X}(\mathbf{Y}^2\mathbf{X}^2)^{q-1}\mathbf{Y}^2\mathbf{X}$; moving the leading $\mathbf{X}$ to the back turns its trace into $\operatorname{tr}\big((\mathbf{Y}^2\mathbf{X}^2)^q\big)$, which is $\operatorname{tr}\big((\mathbf{X}^2\mathbf{Y}^2)^q\big)$ by one more cyclic shift. For the second identity, $\mathbf{A}^2(\mathbf{A}^*)^2 = \mathbf{A}\mathbf{P}\mathbf{A}^*$, and induction on q gives $(\mathbf{A}\mathbf{P}\mathbf{A}^*)^q = \mathbf{A}\,\mathbf{P}(\mathbf{Q}\mathbf{P})^{q-1}\,\mathbf{A}^*$; moving the leading $\mathbf{A}$ to the back turns its trace into $\operatorname{tr}\big(\mathbf{P}(\mathbf{Q}\mathbf{P})^{q-1}\mathbf{Q}\big) = \operatorname{tr}\big((\mathbf{P}\mathbf{Q})^q\big)$.

We now induct on r, proving (a) and (b) simultaneously.

Base $r = 0$**.** Part (a) reads $\operatorname{tr}(\mathbf{A}^*\mathbf{A}) \leq \operatorname{tr}(\mathbf{A}\mathbf{A}^*)$, an equality by Theorem 0.9.6 (3). Part (b) reads $\operatorname{tr}(\mathbf{X}\mathbf{Y}) \leq \operatorname{tr}(\mathbf{X}\mathbf{Y})$.

Step. Assume (a) and (b) for r, and write $q = 2^r$.

Part (b) for $2q$. Put $\mathbf{A} = \mathbf{X}\mathbf{Y}$, so $\mathbf{A}^* = \mathbf{Y}\mathbf{X}$ because $\mathbf{X}$ and $\mathbf{Y}$ are Hermitian, and put $\mathbf{M} = \mathbf{A}^q = (\mathbf{X}\mathbf{Y})^q$. Then $\mathbf{M}^2 = (\mathbf{X}\mathbf{Y})^{2q}$ and $\mathbf{M}^*\mathbf{M} = (\mathbf{A}^*)^q\mathbf{A}^q$. The number $\operatorname{tr}(\mathbf{M}^2) = \operatorname{tr}\big((\mathbf{X}\mathbf{Y})^{2q}\big)$ is real and ≥ 0 by Lemma 20.12.2, so it equals its own absolute value, and Claim 1 gives

$$\operatorname{tr}\big((\mathbf{X}\mathbf{Y})^{2q}\big) \leq \big|\operatorname{tr}(\mathbf{M}^2)\big| \leq \operatorname{tr}\big((\mathbf{A}^*)^q\mathbf{A}^q\big).$$

By the inductive hypothesis (a),

$$\operatorname{tr}\big((\mathbf{A}^*)^q\mathbf{A}^q\big) \leq \operatorname{tr}\big((\mathbf{A}\mathbf{A}^*)^q\big) = \operatorname{tr}\big((\mathbf{X}\mathbf{Y}^2\mathbf{X})^q\big) = \operatorname{tr}\big((\mathbf{X}^2\mathbf{Y}^2)^q\big),$$

the last step by Claim 2. Now $\mathbf{X}^2 = \mathbf{X}^*\mathbf{X} \succeq 0$ and $\mathbf{Y}^2 \succeq 0$ by Theorem 12.1.4 (c), so the inductive hypothesis (b) applies to the pair $\mathbf{X}^2, \mathbf{Y}^2$ and gives

$$\operatorname{tr}\big((\mathbf{X}^2\mathbf{Y}^2)^q\big) \leq \operatorname{tr}\big(\mathbf{X}^{2q}\mathbf{Y}^{2q}\big).$$

Chaining the three displays proves (b) for $2q$.

Part (a) for $2q$. Put $\mathbf{B} = \mathbf{A}^2$, so $\mathbf{B}^* = (\mathbf{A}^*)^2$, $\mathbf{A}^{2q} = \mathbf{B}^q$ and $(\mathbf{A}^*)^{2q} = (\mathbf{B}^*)^q$. The inductive hypothesis (a), applied to $\mathbf{B}$, and then Claim 2 give

$$\operatorname{tr}\big((\mathbf{A}^*)^{2q}\mathbf{A}^{2q}\big) = \operatorname{tr}\big((\mathbf{B}^*)^q\mathbf{B}^q\big) \le \operatorname{tr}\big((\mathbf{B}\mathbf{B}^*)^q\big) = \operatorname{tr}\big((\mathbf{P}\mathbf{Q})^q\big),$$

with $\mathbf{P} = \mathbf{A}\mathbf{A}^*$ and $\mathbf{Q} = \mathbf{A}^*\mathbf{A}$, both positive semidefinite by Theorem 12.1.4 (c). The inductive hypothesis (b) applied to $\mathbf{P}, \mathbf{Q}$ gives $\operatorname{tr}\big((\mathbf{P}\mathbf{Q})^q\big) \le \operatorname{tr}(\mathbf{P}^q\mathbf{Q}^q)$. Since $\mathbf{P}^q$ and $\mathbf{Q}^q$ are Hermitian, $\operatorname{tr}(\mathbf{P}^q\mathbf{Q}^q) = \langle \mathbf{P}^q, \mathbf{Q}^q\rangle$, and this number is real and ≥ 0 by Lemma 20.12.2, both matrices being positive semidefinite. So Theorem 10.1.5 gives

$$\operatorname{tr}(\mathbf{P}^q\mathbf{Q}^q) = \langle \mathbf{P}^q, \mathbf{Q}^q\rangle \le \|\mathbf{P}^q\|_F \|\mathbf{Q}^q\|_F = \operatorname{tr}(\mathbf{P}^{2q})^{1/2}\operatorname{tr}(\mathbf{Q}^{2q})^{1/2}.$$

Write $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$ for a singular value decomposition (Theorem 12.8.1), with $\mathbf{\Sigma} = \operatorname{diag}(\sigma_1, \dots, \sigma_n)$. Then $\mathbf{P} = \mathbf{U}\mathbf{\Sigma}^2\mathbf{U}^*$ and $\mathbf{Q} = \mathbf{V}\mathbf{\Sigma}^2\mathbf{V}^*$, so $\mathbf{P}$ and $\mathbf{Q}$ are both unitarily similar to $\mathbf{\Sigma}^2$ and therefore have the same eigenvalues with multiplicity. Hence $\operatorname{tr}(\mathbf{P}^{2q}) = \operatorname{tr}(\mathbf{Q}^{2q})$, the displayed bound is $\operatorname{tr}(\mathbf{P}^{2q})$, and

$$\operatorname{tr}\big((\mathbf{A}^*)^{2q}\mathbf{A}^{2q}\big) \le \operatorname{tr}(\mathbf{P}^{2q}) = \operatorname{tr}\big((\mathbf{A}\mathbf{A}^*)^{2q}\big).$$

This is (a) for $2q$, and the induction is complete.

■

The restriction to $m = 2^r$ is a restriction of this proof, not of the truth: (b) holds for every integer $m \ge 1$. It even holds for every real $m \ge 1$, once $(\mathbf{X}\mathbf{Y})^m$ is read as $(\mathbf{X}^{1/2}\mathbf{Y}\mathbf{X}^{1/2})^m$, which Lemma 20.12.2 says is the same thing for integer exponents and which is the only reading available for the others, since $\mathbf{X}\mathbf{Y}$ is neither Hermitian nor positive semidefinite. The general case is a theorem of Lieb and Thirring and is not proved here; nothing below needs it, because a limit along the powers of two is all Lie's formula asks for.

20.12.3 The inequality of Golden and Thompson

Now the two halves fit together. Lie's formula writes $e^{\mathbf{A}+\mathbf{B}}$ as a limit of m-th powers of $e^{\mathbf{A}/m}e^{\mathbf{B}/m}$, and the trace power inequality moves the exponent m off the product and onto the two factors, where it reassembles $e^{\mathbf{A}}$ and $e^{\mathbf{B}}$.

Theorem 20.12.4 — The Golden–Thompson Inequality

Let $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$ be Hermitian. Then

$$\operatorname{tr} e^{\mathbf{A}+\mathbf{B}} \;\le\; \operatorname{tr}\big(e^{\mathbf{A}}e^{\mathbf{B}}\big).$$

Both sides are real and positive, and equality holds if $\mathbf{A}\mathbf{B} = \mathbf{B}\mathbf{A}$.

Idea. Run the trace power inequality at the m-th root of each exponential and let m run through the powers of two. At each m the right-hand side is exactly $\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}})$, independent of m, while the left-hand side converges to $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}}$ by Lie's formula. A non-strict inequality survives a limit.

Proof. Fix $r \geq 0$ and put $m = 2^r$, $\mathbf{X} = e^{\mathbf{A}/m}$ and $\mathbf{Y} = e^{\mathbf{B}/m}$. Since $\mathbf{A}/m$ is Hermitian with spectral resolution $\sum_i \mu_i \mathbf{P}_i$, Theorem 11.8.5 (a) gives $\mathbf{X} = \sum_i e^{\mu_i}\mathbf{P}_i$, which is Hermitian with all eigenvalues $e^{\mu_i} > 0$; so $\mathbf{X} \succ 0$ by Theorem 12.1.5 (b), and likewise $\mathbf{Y} \succ 0$. As in Step 1 of the proof of Lemma 20.12.1, $\mathbf{X}^m = e^{\mathbf{A}}$ and $\mathbf{Y}^m = e^{\mathbf{B}}$.

By Lemma 20.12.3 (b),

$$\operatorname{tr}\Big(\big(e^{\mathbf{A}/m}e^{\mathbf{B}/m}\big)^m\Big) \leq \operatorname{tr}\big(\mathbf{X}^m\mathbf{Y}^m\big) = \operatorname{tr}\big(e^{\mathbf{A}}e^{\mathbf{B}}\big).$$

The right side does not depend on r. By Lemma 20.12.1 the matrices $\big(e^{\mathbf{A}/m}e^{\mathbf{B}/m}\big)^m$ converge entrywise to $e^{\mathbf{A}+\mathbf{B}}$ as $m = 2^r \to \infty$, so their traces, being sums of n entries, converge to $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}}$. A non-strict inequality survives a limit, so $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}} \leq \operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}})$.

Both sides are real and ≥ 0: the left because $\mathbf{A}+\mathbf{B}$ is Hermitian, so $e^{\mathbf{A}+\mathbf{B}} \succ 0$ by the argument just given, and the right by Lemma 20.12.2 with $k = 1$. They are in fact positive, since a positive definite matrix has positive trace. If $\mathbf{AB} = \mathbf{BA}$, then $e^{\mathbf{A}}e^{\mathbf{B}} = e^{\mathbf{A}+\mathbf{B}}$ by Theorem 9.9.4 (d), and the two sides are equal.

■

A two-by-two family shows that the inequality is genuinely an inequality, and lets the reader see what the two sides look like.

Example. (The inequality on a two-by-two family)

For real a, b let

$$\mathbf{A} = \begin{pmatrix} a & 0 \\ 0 & -a \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 0 & b \\ b & 0 \end{pmatrix}.$$

Compute both sides of Golden–Thompson, and decide when the inequality is strict.

Solution. Both matrices are real symmetric. Write $\mathbf{M} = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, so that $\mathbf{B} = b\mathbf{M}$ and $\mathbf{M}^2 = \mathbf{I}$. Then $\mathbf{B}^{2m} = b^{2m}\mathbf{I}$ and $\mathbf{B}^{2m+1} = b^{2m+1}\mathbf{M}$, so splitting the exponential series into even and odd terms gives

$$e^{\mathbf{B}} = \cosh(b)\,\mathbf{I} + \sinh(b)\,\mathbf{M} = \begin{pmatrix} \cosh b & \sinh b \\ \sinh b & \cosh b \end{pmatrix},$$

for every real b. Since $e^{\mathbf{A}} = \operatorname{diag}(e^a, e^{-a})$, the diagonal entries of $e^{\mathbf{A}}e^{\mathbf{B}}$ are $e^a \cosh b$ and $e^{-a}\cosh b$, whence

$$\operatorname{tr}\big(e^{\mathbf{A}}e^{\mathbf{B}}\big) = (e^a + e^{-a})\cosh b = 2\cosh a\,\cosh b.$$

For the left side, $\mathbf{A}+\mathbf{B} = \left(\begin{smallmatrix} a & b \\ b & -a \end{smallmatrix}\right)$ has trace 0 and determinant $-(a^2+b^2)$, so its eigenvalues are $\pm d$ with $d = \sqrt{a^2+b^2}$. By Theorem 11.8.5 (a) the eigenvalues of $e^{\mathbf{A}+\mathbf{B}}$ are e^d and e^{-d}, so $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}} = 2\cosh d$ by Theorem 8.3.3. The inequality therefore reads

$$\cosh\sqrt{a^2+b^2} \;\leq\; \cosh a\,\cosh b,$$

a statement about numbers, and it can be checked term by term. Expanding both sides as power series with non-negative terms, the coefficient of $a^{2i}b^{2j}$ is $\binom{i+j}{i}/(2i+2j)!$ on the left and $1/\big((2i)!(2j)!\big)$ on the right, so what is needed is $\binom{i+j}{i} \leq \binom{2i+2j}{2i}$. That holds

because doubling each of i chosen items out of $i+j$ produces $2i$ chosen items out of $2i+2j$, injectively; and it is strict as soon as $i,j \geq 1$, since then some $2i$-subset splits a doubled pair and so is not in the image.

Equality therefore forces every term with $i,j \geq 1$ to vanish, that is $a=0$ or $b=0$ — exactly the cases where $\mathbf{A}$ and $\mathbf{B}$ commute. For $a=b=1$ the two sides are $2\cosh\sqrt{2} \approx 4.3564$ and $2\cosh^2 1 \approx 4.7622$.

Warning. **Golden–Thompson is a statement about traces and about nothing else.** It is tempting to guess the Loewner-order version $e^{\mathbf{A}+\mathbf{B}} \preceq e^{\mathbf{A}/2}e^{\mathbf{B}}e^{\mathbf{A}/2}$, whose right side is Hermitian and positive semidefinite and has the same trace as $e^{\mathbf{A}}e^{\mathbf{B}}$. It is false in general. Indeed both sides have the same determinant, namely $e^{\operatorname{tr}\mathbf{A}+\operatorname{tr}\mathbf{B}}$ by Theorem 9.9.4 (e) — and if $\mathbf{M} \succeq \mathbf{N} \succ 0$ with $\det\mathbf{M} = \det\mathbf{N}$, then $\mathbf{Z} = \mathbf{N}^{-1/2}\mathbf{M}\mathbf{N}^{-1/2} \succeq \mathbf{I}$ by Theorem 12.5.3 (a), so all eigenvalues of $\mathbf{Z}$ are ≥ 1 while their product is $\det\mathbf{Z} = \det\mathbf{M}/\det\mathbf{N} = 1$; hence they are all 1, the Hermitian matrix $\mathbf{Z}$ equals $\mathbf{I}$, and $\mathbf{M} = \mathbf{N}^{1/2}\mathbf{Z}\mathbf{N}^{1/2} = \mathbf{N}$. So the Loewner inequality would force $e^{\mathbf{A}+\mathbf{B}} = e^{\mathbf{A}/2}e^{\mathbf{B}}e^{\mathbf{A}/2}$, and taking traces would force equality in Golden–Thompson, which Example (The inequality on a two-by-two family) refutes for $a=b=1$.

20.12.4 Three matrices are one too many

Golden–Thompson looks as though it should iterate. It does not. The three-matrix statement

$$\operatorname{tr} e^{\mathbf{A}+\mathbf{B}+\mathbf{C}} \;\leq\; \operatorname{tr}\bigl(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}}\bigr)$$

is **false**, and the failure is not marginal: the right side can be negative while the left side, a trace of a positive definite matrix, is positive. A family of two-by-two real symmetric matrices shows it, exactly.

Example. (The three-matrix version fails)

Let $t>0$ and let $\mathbf{P}_1,\mathbf{P}_2,\mathbf{P}_3$ be the orthogonal projections of $\mathbb{R}^2$ onto the three lines through the origin at angles 0, $2\pi/3$ and $4\pi/3$:

$$\mathbf{P}_1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad \mathbf{P}_2 = \frac{1}{4}\begin{pmatrix} 1 & -\sqrt{3} \\ -\sqrt{3} & 3 \end{pmatrix}, \quad \mathbf{P}_3 = \frac{1}{4}\begin{pmatrix} 1 & \sqrt{3} \\ \sqrt{3} & 3 \end{pmatrix}.$$

Put $\mathbf{A} = t\mathbf{P}_1$, $\mathbf{B} = t\mathbf{P}_2$, $\mathbf{C} = t\mathbf{P}_3$, all symmetric. Compute both sides of the three-matrix inequality and show that it fails.

Solution. Each $\mathbf{P}_i$ is $\mathbf{u}_i\mathbf{u}_i^{\top}$ for a unit vector $\mathbf{u}_i$, with $\mathbf{u}_1 = (1,0)$, $\mathbf{u}_2 = (-\tfrac{1}{2},\tfrac{\sqrt{3}}{2})$, $\mathbf{u}_3 = (-\tfrac{1}{2},-\tfrac{\sqrt{3}}{2})$; each is symmetric with $\mathbf{P}_i^2 = \mathbf{P}_i$. Adding the three matrices gives $\mathbf{P}_1+\mathbf{P}_2+\mathbf{P}_3 = \tfrac{3}{2}\mathbf{I}$, so $\mathbf{A}+\mathbf{B}+\mathbf{C} = \tfrac{3t}{2}\mathbf{I}$ and

$$\operatorname{tr} e^{\mathbf{A}+\mathbf{B}+\mathbf{C}} = 2e^{3t/2}.$$

For the right side, $\mathbf{P}_i^2 = \mathbf{P}_i$ makes the exponential series collapse: $e^{t\mathbf{P}} = \mathbf{I} + \alpha\mathbf{P}$ with $\alpha = e^t - 1$, because $\sum_{j\geq 1} t^j\mathbf{P}^j/j! = \bigl(\sum_{j\geq 1} t^j/j!\bigr)\mathbf{P}$. Expanding the product of three such factors and using $\operatorname{tr}\mathbf{I} = 2$, $\operatorname{tr}\mathbf{P}_i = 1$, $\operatorname{tr}(\mathbf{P}_i\mathbf{P}_j) = (\mathbf{u}_i\cdot\mathbf{u}_j)^2$ and $\operatorname{tr}(\mathbf{P}_1\mathbf{P}_2\mathbf{P}_3) =$

$(\mathbf{u}_1 \cdot \mathbf{u}_2)(\mathbf{u}_2 \cdot \mathbf{u}_3)(\mathbf{u}_3 \cdot \mathbf{u}_1)$,

$$\operatorname{tr}\bigl(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}}\bigr) = 2 + 3\alpha + \tfrac{3}{4}\alpha^2 - \tfrac{1}{8}\alpha^3,$$

since each pairwise dot product is $-\frac{1}{2}$, so each $\operatorname{tr}(\mathbf{P}_i\mathbf{P}_j) = \frac{1}{4}$ and the triple product is $-\frac{1}{8}$. In terms of t this is

$$\operatorname{tr}\bigl(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}}\bigr) = \tfrac{1}{8}\bigl(-e^{3t} + 9e^{2t} + 9e^{t} - 1\bigr).$$

The cubic term is negative, and for large t it wins. Precisely, if $e^t \geq 10$ then $e^{2t} \geq 10e^t$ and $e^{3t} \geq 10e^{2t} = 9e^{2t} + e^{2t} \geq 9e^{2t} + 10e^t$, so the bracket is negative and $\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}}) < 0$, while $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}+\mathbf{C}} = 2e^{3t/2} > 0$. Taking $t = 3$, where $e^3 > 20$, already does this: the two sides are $2e^{4.5} \approx 180.0$ and $\frac{1}{8}(-e^9 + 9e^6 + 9e^3 - 1) \approx -536.6$.

The failure is not confined to large t. At $t = 1$ the two sides are $2e^{3/2} \approx 8.9634$ and $\frac{1}{8}(-e^3 + 9e^2 + 9e - 1) \approx 8.7351$, and at $t = 2$ they are $2e^3 \approx 40.171$ and $\frac{1}{8}(-e^6 + 9e^4 + 9e^2 - 1) \approx 19.182$.

The numbers in the example are exact, and the two closed forms may be compared by hand; only their decimal expansions are approximations.

Remark. There is a second, more basic obstruction. For three Hermitian matrices the number $\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}})$ need not be **real**, so no inequality can even be written down. With

$$\mathbf{A} = a\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \mathbf{B} = b\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \mathbf{C} = c\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

each of the three squares is a multiple of $\mathbf{I}$, so each exponential splits into a hyperbolic cosine times $\mathbf{I}$ plus a hyperbolic sine times the matrix, and multiplying out gives

$$\operatorname{tr}\bigl(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}}\bigr) = 2\cosh a \cosh b \cosh c + 2i \sinh a \sinh b \sinh c,$$

because the product of the three matrices above is $i\mathbf{I}$ while every shorter product among them has trace 0. The imaginary part is non-zero whenever a, b, c are all non-zero. With two matrices this cannot happen, by Lemma 20.12.2.

Remark. Two of the three matrices commuting is enough to restore the inequality, and exercise Exercise (C1: Two out of three is enough) asks for the three cases. So the example above is as economical as it can be: no two of $\mathbf{P}_1, \mathbf{P}_2, \mathbf{P}_3$ commute.

20.12.5 Klein's inequality and relative entropy

Golden–Thompson is one of a family of trace inequalities whose proofs all end in the same place: a scalar convexity inequality summed against non-negative weights that add to one. The next theorem is the cleanest member of the family. It needs one fact about convex functions of a real variable, which Chapter 17 recorded only in an exercise, so we prove it here.

Lemma 20.12.5 — A Convex Function Lies Above Its Tangent

Let $I \subseteq \mathbb{R}$ be an open interval and let $f\colon I \to \mathbb{R}$ be convex and differentiable. Then

$$f(s) \;\geq\; f(t) + f'(t)(s-t) \qquad \text{for all } s,t \in I.$$

Proof. Fix $s,t \in I$. If $s = t$ both sides are $f(t)$. Assume $s \neq t$ and let $0 < \theta \leq 1$. The point $t + \theta(s-t) = (1-\theta)t + \theta s$ lies in I, and Definition 17.10.1 gives

$$f\big(t + \theta(s-t)\big) \leq (1-\theta)f(t) + \theta f(s),$$

that is, $\big(f(t+\theta(s-t)) - f(t)\big)/\theta \leq f(s) - f(t)$. Writing $h = \theta(s-t)$, which is non-zero and tends to 0 as $\theta \to 0^+$, the left side equals

$$(s-t)\cdot\frac{f(t+h)-f(t)}{h} \;\longrightarrow\; (s-t)f'(t),$$

by differentiability of f at t. A non-strict inequality survives a limit, so $(s-t)f'(t) \leq f(s) - f(t)$, which is the claim.

■

Theorem 20.12.6 — Klein's Inequality

Let $I \subseteq \mathbb{R}$ be an open interval and let $f\colon I \to \mathbb{R}$ be convex and differentiable. Let $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$ be Hermitian with $\operatorname{spec}(\mathbf{A}) \subseteq I$ and $\operatorname{spec}(\mathbf{B}) \subseteq I$. Then

$$\operatorname{tr}\big(f(\mathbf{A}) - f(\mathbf{B}) - (\mathbf{A}-\mathbf{B})f'(\mathbf{B})\big) \;\geq\; 0,$$

where $f(\mathbf{A})$, $f(\mathbf{B})$ and $f'(\mathbf{B})$ are the functional calculus of Definition 11.8.2.

Idea. Compute the trace in an orthonormal eigenbasis of $\mathbf{B}$. Each diagonal entry then involves $\mathbf{B}$ only through one eigenvalue μ_j, and involves $\mathbf{A}$ only through the numbers $c_{ij} = |\langle \mathbf{v}_j, \mathbf{u}_i\rangle|^2$, the overlaps between the two eigenbases. Those numbers are non-negative and each column of the array sums to 1, which is exactly what is needed to write the whole trace as a weighted average of the scalar quantities $f(\lambda_i) - f(\mu_j) - f'(\mu_j)(\lambda_i - \mu_j)$. Every one of those is ≥ 0 by Lemma 20.12.5.

Proof. By Corollary 11.4.3 there are orthonormal bases $(\mathbf{u}_1,\dots,\mathbf{u}_n)$ and $(\mathbf{v}_1,\dots,\mathbf{v}_n)$ of $\mathbb{C}^n$ with $\mathbf{A}\mathbf{u}_i = \lambda_i \mathbf{u}_i$ and $\mathbf{B}\mathbf{v}_j = \mu_j \mathbf{v}_j$; all λ_i and μ_j lie in I. Put $c_{ij} = |\langle \mathbf{v}_j, \mathbf{u}_i\rangle|^2 \geq 0$. Expanding $\mathbf{v}_j$ in the orthonormal basis $(\mathbf{u}_i)$ gives $\sum_i c_{ij} = \|\mathbf{v}_j\|^2 = 1$ for each j.

For any $\mathbf{M} \in M_n(\mathbb{C})$ we have $\operatorname{tr}\mathbf{M} = \sum_j \langle \mathbf{M}\mathbf{v}_j, \mathbf{v}_j\rangle$: with $\mathbf{V}$ the unitary matrix whose columns are the $\mathbf{v}_j$, the sum is $\operatorname{tr}(\mathbf{V}^*\mathbf{M}\mathbf{V}) = \operatorname{tr}(\mathbf{M}\mathbf{V}\mathbf{V}^*) = \operatorname{tr}\mathbf{M}$ by Theorem 0.9.6 (3). We evaluate the three terms at $\mathbf{v}_j$.

By Definition 11.8.2, $f(\mathbf{A})\mathbf{u}_i = f(\lambda_i)\mathbf{u}_i$, so expanding $\mathbf{v}_j = \sum_i \langle \mathbf{v}_j, \mathbf{u}_i\rangle \mathbf{u}_i$ and using orthonormality,

$$\langle f(\mathbf{A})\mathbf{v}_j, \mathbf{v}_j\rangle = \sum_i f(\lambda_i)\, c_{ij}, \qquad \langle \mathbf{A}\mathbf{v}_j, \mathbf{v}_j\rangle = \sum_i \lambda_i\, c_{ij}.$$

Also $f(\mathbf{B})\mathbf{v}_j = f(\mu_j)\mathbf{v}_j$ and $f'(\mathbf{B})\mathbf{v}_j = f'(\mu_j)\mathbf{v}_j$, so $\langle f(\mathbf{B})\mathbf{v}_j, \mathbf{v}_j\rangle = f(\mu_j)$ and

$$\langle (\mathbf{A}-\mathbf{B})f'(\mathbf{B})\mathbf{v}_j, \mathbf{v}_j\rangle = f'(\mu_j)\Big(\sum_i \lambda_i c_{ij} - \mu_j\Big).$$

Summing over j, and using $\sum_i c_{ij} = 1$ to write $f(\mu_j) = \sum_i c_{ij} f(\mu_j)$ and $\mu_j = \sum_i c_{ij}\mu_j$,

$$\operatorname{tr}\big(f(\mathbf{A}) - f(\mathbf{B}) - (\mathbf{A}-\mathbf{B})f'(\mathbf{B})\big) = \sum_{i,j} c_{ij}\,\big[\, f(\lambda_i) - f(\mu_j) - f'(\mu_j)(\lambda_i - \mu_j)\,\big].$$

Every bracket is ≥ 0 by Lemma 20.12.5, and every $c_{ij} \geq 0$. This proves the inequality.

■

The corollary that made Klein's inequality famous concerns density matrices, the positive semidefinite matrices of trace 1 that Chapter 17 §08 met as a convex body (Definition 17.8.3). It needs the derivative of the logarithm, which the book has not yet computed.

Lemma 20.12.7 — The Derivative of the Logarithm

The function $\log\colon (0,\infty) \to \mathbb{R}$ of Lemma 17.11.1 is differentiable with $\log'(y) = 1/y$. Consequently $g(t) = t\log t$ is differentiable on $(0,\infty)$ with $g'(t) = \log t + 1$ and $g''(t) = 1/t$, and g is strictly convex there.

Proof. *Continuity.* By Lemma 17.11.1 (a) and (b), $\exp\colon \mathbb{R} \to (0,\infty)$ is a strictly increasing bijection, so log is strictly increasing. Fix $y > 0$, put $s = \log y$ and let $\varepsilon > 0$. Then $e^{s-\varepsilon} < y < e^{s+\varepsilon}$, and for y' in that open interval, applying the increasing log gives $s - \varepsilon < \log y' < s + \varepsilon$. So log is continuous at y.

Differentiability. Let $h \neq 0$ be small enough that $y + h > 0$, and put $u = \log(y+h) - s$, so that $y + h = e^{s+u} = ye^u$ and $h = y(e^u - 1)$. Since log is injective, $u \neq 0$, and $u \to 0$ as $h \to 0$ by continuity. Hence

$$\frac{\log(y+h) - \log y}{h} = \frac{u}{y(e^u - 1)} \longrightarrow \frac{1}{y},$$

because $(e^u - 1)/u \to 1$: the exponential is its own derivative (Theorem 9.9.4 (b) with $n = 1$), and its value at 0 is 1.

The function $t\log t$. For $t > 0$ and small $h \neq 0$,

$$\frac{(t+h)\log(t+h) - t\log t}{h} = t\cdot\frac{\log(t+h) - \log t}{h} + \log(t+h),$$

which tends to $t\cdot(1/t) + \log t = 1 + \log t$, using continuity of log. Differentiating once more, $g''(t) = 1/t > 0$, so g is strictly convex by Lemma 17.10.5.

■

Corollary 20.12.8 — Non-negativity of the Relative Entropy

Let $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$ be positive definite with $\operatorname{tr}\mathbf{A} = \operatorname{tr}\mathbf{B} = 1$. Then

$$\operatorname{tr}\big(\mathbf{A}(\log\mathbf{A} - \log\mathbf{B})\big) \;\geq\; 0.$$

Proof. Apply Theorem 20.12.6 on $I = (0,\infty)$ to $f(t) = t\log t$, which is convex and differentiable with $f'(t) = \log t + 1$ by Lemma 20.12.7. Both spectra lie in I by Theorem 12.1.5 (b). By Theorem 11.8.3 (b), $f'(\mathbf{B}) = \log\mathbf{B} + \mathbf{I}$. So Klein's inequality reads

$$\operatorname{tr}(\mathbf{A}\log\mathbf{A}) - \operatorname{tr}(\mathbf{B}\log\mathbf{B}) - \operatorname{tr}\big((\mathbf{A}-\mathbf{B})(\log\mathbf{B} + \mathbf{I})\big) \;\geq\; 0.$$

Expanding the last trace by linearity, it equals $\operatorname{tr}(\mathbf{A}\log\mathbf{B}) - \operatorname{tr}(\mathbf{B}\log\mathbf{B}) + \operatorname{tr}\mathbf{A} - \operatorname{tr}\mathbf{B}$. Substituting and canceling $\operatorname{tr}(\mathbf{B}\log\mathbf{B})$,

$$\operatorname{tr}(\mathbf{A}\log\mathbf{A}) - \operatorname{tr}(\mathbf{A}\log\mathbf{B}) - \operatorname{tr}\mathbf{A} + \operatorname{tr}\mathbf{B} \;\geq\; 0,$$

and $\operatorname{tr}\mathbf{A} = \operatorname{tr}\mathbf{B} = 1$ removes the last two terms. ∎

The quantity $\operatorname{tr}\big(\mathbf{A}(\log\mathbf{A} - \log\mathbf{B})\big)$ is the **relative entropy** of $\mathbf{A}$ with respect to $\mathbf{B}$, and the corollary says it is a genuine measure of discrepancy: never negative, and zero when $\mathbf{A} = \mathbf{B}$. For diagonal $\mathbf{A}$ and $\mathbf{B}$ it is the familiar sum $\sum_i a_i(\log a_i - \log b_i)$ over two probability vectors, so the corollary contains the scalar statement as its commuting case.

Remark. Klein's inequality is the trace-level shadow of §02's Lemma 20.2.7 and Theorem 20.2.8: all three say that a convex function applied to a Hermitian matrix behaves, after a trace, like a convex function applied to a weighted average of eigenvalues, the weights being the overlaps between two eigenbases. The array (c_{ij}) in the proof above is doubly stochastic (Definition 17.8.4), and Chapter 19 §05 used the same array for Hoffman–Wielandt. It is the same object doing the same job.

20.12.6 What is stated here and not proved

One theorem belongs in this section by subject and is beyond its means.

Lieb's concavity theorem. *Let $\mathbf{X} \in M_n(\mathbb{C})$ be fixed and let $p, q \geq 0$ with $p + q \leq 1$. Then the map*

$$(\mathbf{A}, \mathbf{B}) \;\longmapsto\; \operatorname{tr}\big(\mathbf{X}^*\mathbf{A}^p\mathbf{X}\mathbf{B}^q\big)$$

is jointly concave on pairs of positive definite matrices. This is a theorem of Lieb, and it is **not proved in this book**. What it needs is machinery this chapter does not build: either the theory of tensor products of positive maps, or a differentiation argument through the integral representations of §10 that would have to control two variables at once. It is recorded here because it is the natural strengthening of everything above — Golden–Thompson and the concavity of $(\mathbf{A}, \mathbf{B}) \mapsto \operatorname{tr} e^{\log\mathbf{A} + \log\mathbf{B}}$ both follow from it — and because a reader who meets it elsewhere should know where it sits.

Nothing in this book depends on it. No statement in Chapters 0 to 20 is proved using Lieb's theorem, and no later chapter is promised a consequence of it.

20.12.7 Summary and transfer

Five earlier chapters left inequalities unproved, each of them an inequality that was supposed to hold for **every** unitarily invariant norm, or for **every** convex function. This chapter proved them, and the reason they could all be proved at once is that they are all the same statement about vectors: a majorization.

- **Majorization is a doubly stochastic map.** §01 proved the theorem of Hardy, Littlewood and Pólya, Theorem 20.1.3, that $\mathbf{x} \prec \mathbf{y}$ exactly when $\mathbf{x} = \mathbf{D}\mathbf{y}$ for a doubly stochastic $\mathbf{D}$, and with Birkhoff's theorem from Chapter 18, exactly when $\mathbf{x}$ lies in the convex hull of the permutations of $\mathbf{y}$ (Corollary 20.1.4).
- **Hence every convex function.** §02's Theorem 20.2.1 turned that into $\sum_i \phi(x_i) \le \sum_i \phi(y_i)$, and Theorem 20.2.8 turned it into the convexity of $\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A})$.
- **Hence every unitarily invariant norm.** §03 identified the symmetric gauge functions and showed that they are monotone under weak majorization (Theorem 20.3.4); §04's Theorem 20.4.3 matched them one for one with the unitarily invariant norms of Definition 20.4.1, through $|||\mathbf{A}||| = \Phi(\sigma(\mathbf{A}))$; §05 proved von Neumann's trace inequality; and §06's Theorem 20.6.1 closed the circle, making $\sigma(\mathbf{A}) \prec_w \sigma(\mathbf{B})$ *equivalent* to $|||\mathbf{A}||| \le |||\mathbf{B}|||$ for every such norm.
- **The applications.** §06 deduced Eckart–Young (Corollary 20.6.2) and the nearest-unitary theorem (Corollary 20.6.4) in every unitarily invariant norm; §07 did the same for Lidskii (Theorem 20.7.2) and Mirsky (Theorem 20.7.4).
- **The order-theoretic half.** §08 studied operator convexity and proved the Hansen–Pedersen–Jensen inequality (Theorem 20.8.5); §09 proved that operator monotonicity of order n is exactly positivity of every $n \times n$ Loewner matrix (Theorem 20.9.5); §10 assembled Loewner's theorem (Theorem 20.10.4), and with it Corollary 20.10.8 and Corollary 20.10.9; §11 built the matrix geometric mean (Definition 20.11.1).
- **The exponential.** This section proved Lie's product formula, the trace power inequality, Golden–Thompson and Klein's inequality, and showed that three matrices break the pattern.

Six moves did the work of the chapter.

- **A majorization is a doubly stochastic map.** To prove something for all $\mathbf{x} \prec \mathbf{y}$, write $\mathbf{x} = \mathbf{D}\mathbf{y}$ and let convexity act one row at a time (§01, §02). *Transfer:* when a hypothesis is a family of inequalities between partial sums, look for the linear map that realizes it; the inequalities are usually the vertices of a polytope in disguise.
- **A symmetric gauge turns a weak majorization into a norm inequality.** A norm that cannot tell coordinates apart, and cannot see their signs, is monotone along $\prec_w$ (§03, §04). *Transfer:* to prove one inequality for a whole family of norms, find the single combinatorial statement about the underlying numbers that all of them respect.
- **A Hermitian dilation turns singular values into eigenvalues.** Chapter 16 §09's $\mathcal{H}(\mathbf{A})$ has eigenvalues $\pm\sigma_i(\mathbf{A})$, so every theorem about eigenvalues of Hermitian matrices has a singular-value twin (§04, §07). *Transfer:* when a result is known for Hermitian matrices and wanted for all matrices, look for the Hermitian matrix whose spectrum encodes the data.
- **The Schur product theorem turns a Loewner matrix into monotonicity.** The derivative of f at a diagonal matrix is a Hadamard product with the Loewner matrix, and Chapter 12 §07 says that a Hadamard product of positive semidefinite matrices is positive semidefinite (§09). *Transfer:* to show that a matrix-valued function is increasing, differentiate it and recognize the derivative as an entrywise product.

- **A limit of Riemann sums carries the Loewner order through an integral.** The positive semidefinite cone is closed, so an integral of positive semidefinite matrices is positive semidefinite (§10). *Transfer:* an order defined by a closed convex cone survives any limit, so it survives integration; the only work is building the integral.
- **Lie's product formula turns a sum in the exponent into a product.** Lemma 20.12.1 replaces $e^{\mathbf{A}+\mathbf{B}}$, which nothing can be said about directly, by a limit of products, each of which can be attacked with Cauchy–Schwarz (this section). *Transfer:* when two operations fail to commute, split one of them into k small steps, estimate the error of a single step as $O(1/k^2)$, and let telescoping absorb the factor k.

The chapter paid the following promises, in the words in which they were made.

The promise	Made in	Paid by
Hardy–Littlewood–Pólya, "$\mathbf{x} \prec \mathbf{y}$ exactly when $\mathbf{x} = \mathbf{D}\mathbf{y}$ for a doubly stochastic $\mathbf{D}$"	Chapter 18 §09	§01
"the general consequences of a majorization $\mathbf{x} \prec \mathbf{y}$, namely $\sum_i \phi(x_i) \le \sum_i \phi(y_i)$ for every convex ϕ"	Chapter 16 §07	§02 and §07
"for the whole class of functions that reverse majorization" (the product is Schur-concave)	Chapter 16 §08	§02
"$\mathbf{A} \mapsto \operatorname{tr} f(\mathbf{A})$ … is proved in Chapter 20"	Chapter 17 §10	§02
"It has not said which norms are invariant under unitary multiplication, which is Chapter 20"	Chapter 15 §08	§04
"The repair is to apply N_k to the singular values instead of the eigenvalues, which is what Chapter 20 does"	Chapter 16 §06	§04
Eckart–Young "in **every** unitarily invariant norm", by a route that "needs inequalities between the singular values of $\mathbf{A}$ and of $\mathbf{A} - \mathbf{B}$, not a projection argument"	Chapter 12 §10, Chapter 15 §08, Chapter 16 §09	§06
"$\mathbf{W}$ also minimizes the distance in every unitarily invariant norm"	Chapter 12 §09	§06
"with $\phi(t) = t^2$ this is Corollary 19.5.4 again"	Chapter 19 §05	§07
"one statement covering every unitarily invariant norm" (the index-by-index singular-value bound and Mirsky)	Chapter 19 §10 and §11	§07

The promise	Made in	Paid by
"$t \mapsto t^s$ is operator monotone on $[0,\infty)$ exactly for $0 \le s \le 1$", with "the companion fact that $t \mapsto \log t$ is operator monotone while $t \mapsto e^t$ is not"	Chapter 12 §05	§10, modulo (A7)

Some things the chapter did not do. Loewner's theorem is proved here only up to one quoted fact, **(A7)**, the Nevanlinna–Pick characterization of Pick functions; §10 says precisely which implication rests on it, and §09's elementary half — that for a continuously differentiable f, monotonicity of every order is exactly positivity of every Loewner matrix — is proved in full. The Lieb–Thirring inequality, which would remove the restriction to $m = 2^r$ in Lemma 20.12.3, is not proved, and nothing here needs it. Lieb's concavity theorem is stated above and not proved, and nothing in the book depends on it. The equality cases of von Neumann's trace inequality and of Golden–Thompson were treated only in the directions that were needed.

Part V ends here. It began in Chapter 15 with a complaint: nine chapters had said "close" and "small" with nothing to measure by. A norm supplied the yardstick, and the five chapters since have been spent finding out what a yardstick is good for. Chapter 16 made the eigenvalues of a Hermitian matrix into the values of an optimization problem, so that they could be compared. Chapter 17 supplied the language of convexity in which such comparisons live. Chapter 18 studied the one class of non-Hermitian matrices — the non-negative ones — where a comparable theory exists, and produced Birkhoff's theorem, which this chapter used once. Chapter 19 asked how much the answers move when the data move. And Chapter 20 has collected the inequalities that all five chapters kept needing, and shown that they are one inequality seen from different sides. What none of these chapters has done is compute anything: every proof here is an existence or a comparison, and not one of them is an algorithm. That is the subject of Chapter 23.

20.12.8 Exercises

20.12.8.1 A. Check your understanding

Exercise A1.

(a) State the Golden–Thompson inequality, with its hypotheses.

(b) State Lie's product formula, and say for which matrices it holds.

(c) True or false: for Hermitian $\mathbf{A}, \mathbf{B}$ the matrix $e^{\mathbf{A}}e^{\mathbf{B}}$ is positive semidefinite. Justify your answer.

(d) True or false: $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}} \le \operatorname{tr}(e^{\mathbf{B}}e^{\mathbf{A}})$ for Hermitian $\mathbf{A}, \mathbf{B}$. Justify your answer.

(e) True or false: $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}+\mathbf{C}} \le \operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}})$ for Hermitian $\mathbf{A}, \mathbf{B}, \mathbf{C}$. Justify your answer.

(f) Where in the proof of Theorem 20.12.4 is the hypothesis that $\mathbf{A}$ and $\mathbf{B}$ are Hermitian used?

Solution.

(a) For Hermitian $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$, $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}} \le \operatorname{tr}(e^{\mathbf{A}} e^{\mathbf{B}})$ (Theorem 20.12.4). No commutativity is assumed; if $\mathbf{AB} = \mathbf{BA}$ the two sides are equal.

(b) $e^{\mathbf{A}+\mathbf{B}} = \lim_k (e^{\mathbf{A}/k} e^{\mathbf{B}/k})^k$ for **all** $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$, Hermitian or not (Lemma 20.12.1).

(c) False, since positive semidefinite includes Hermitian (Definition 12.1.1 (P1)) and $(e^{\mathbf{A}} e^{\mathbf{B}})^* = e^{\mathbf{B}} e^{\mathbf{A}}$, which equals $e^{\mathbf{A}} e^{\mathbf{B}}$ only when the two exponentials commute. In Example (The inequality on a two-by-two family) with $a = b = 1$,

$$e^{\mathbf{A}} e^{\mathbf{B}} = \begin{pmatrix} e \cosh 1 & e \sinh 1 \\ e^{-1} \sinh 1 & e^{-1} \cosh 1 \end{pmatrix},$$

which is not symmetric because $e \sinh 1 \neq e^{-1} \sinh 1$.

(d) True. $\operatorname{tr}(e^{\mathbf{B}} e^{\mathbf{A}}) = \operatorname{tr}(e^{\mathbf{A}} e^{\mathbf{B}})$ by Theorem 0.9.6 (3), and $\mathbf{A} + \mathbf{B} = \mathbf{B} + \mathbf{A}$, so this is Theorem 20.12.4 with the roles exchanged.

(e) False; see Example (The three-matrix version fails), where the right side is negative and the left side positive. The right side need not even be real (the remark after that example).

(f) In two places. First, to know that $e^{\mathbf{A}/m}$ and $e^{\mathbf{B}/m}$ are positive semidefinite, which is the hypothesis of Lemma 20.12.3 (b). Second, in Lemma 20.12.2, which is what makes $\operatorname{tr}(e^{\mathbf{A}} e^{\mathbf{B}})$ real so that the inequality is a statement about real numbers.

20.12.8.2 B. Practice

Exercise B1: Both sides, exactly.

Let

$$\mathbf{A} = \begin{pmatrix} 0 & 0 \\ 0 & -2 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

(a) Compute $e^{\mathbf{A}}$, $e^{\mathbf{B}}$ and $\operatorname{tr}(e^{\mathbf{A}} e^{\mathbf{B}})$ exactly.

(b) Compute $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}}$ exactly, and verify Theorem 20.12.4 numerically to three decimal places.

Solution.

(a) $\mathbf{A}$ is diagonal, so $e^{\mathbf{A}} = \operatorname{diag}(1, e^{-2})$. Since $\mathbf{B}^2 = \mathbf{I}$, splitting the series into even and odd terms gives $e^{\mathbf{B}} = \cosh(1)\mathbf{I} + \sinh(1)\mathbf{B}$, that is

$$e^{\mathbf{B}} = \begin{pmatrix} \cosh 1 & \sinh 1 \\ \sinh 1 & \cosh 1 \end{pmatrix}.$$

Hence $e^{\mathbf{A}} e^{\mathbf{B}}$ has diagonal entries $\cosh 1$ and $e^{-2} \cosh 1$, so

$$\operatorname{tr}(e^{\mathbf{A}} e^{\mathbf{B}}) = (1 + e^{-2}) \cosh 1 = \frac{(1 + e^{-2})(e + e^{-1})}{2}.$$

Numerically $(1 + 0.135335)(1.543081) = 1.751914$.

(b) $\mathbf{A} + \mathbf{B} = \left(\begin{smallmatrix} 0 & 1 \\ 1 & -2 \end{smallmatrix}\right)$ has trace -2 and determinant -1, so its characteristic polynomial is $x^2 + 2x - 1$ and its eigenvalues are $-1 \pm \sqrt{2}$. A Hermitian matrix has $\operatorname{tr} e^{\mathbf{M}} =$

$\sum_i e^{\lambda_i}$ by Theorem 11.8.5 (a) and Theorem 8.3.3, so

$$\operatorname{tr} e^{\mathbf{A}+\mathbf{B}} = e^{-1+\sqrt{2}} + e^{-1-\sqrt{2}} = 2e^{-1}\cosh\sqrt{2}.$$

Numerically $2(0.367879)(2.178183) = 1.602618$. Indeed $1.603 \le 1.752$, and the inequality is strict because $\mathbf{A}$ and $\mathbf{B}$ do not commute: $\mathbf{AB} = \left(\begin{smallmatrix} 0 & 0 \\ -2 & 0 \end{smallmatrix}\right)$ while $\mathbf{BA} = \left(\begin{smallmatrix} 0 & -2 \\ 0 & 0 \end{smallmatrix}\right)$.

Exercise B2: The trace power inequality on integers.

Let $\mathbf{X} = \operatorname{diag}(2, 1)$ and $\mathbf{Y} = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$.

(a) Check that $\mathbf{X}$ and $\mathbf{Y}$ are positive semidefinite, and compute $\operatorname{tr}\big((\mathbf{XY})^m\big)$ and $\operatorname{tr}(\mathbf{X}^m\mathbf{Y}^m)$ for $m = 1, 2, 4$.

(b) Verify Lemma 20.12.3 (b) in these three cases, and say for which of them it is strict.

Solution.

(a) $\mathbf{X}$ is diagonal, so its eigenvalues are 2 and 1; $\mathbf{Y}$ is symmetric with trace 2 and determinant 0, so its eigenvalues are 2 and 0. Both lists are non-negative, so $\mathbf{X} \succeq 0$ and $\mathbf{Y} \succeq 0$ by Theorem 12.1.4 (b).
Now $\mathbf{XY} = \left(\begin{smallmatrix} 2 & 2 \\ 1 & 1 \end{smallmatrix}\right)$, which has trace 3 and determinant 0, so its eigenvalues are 3 and 0 and $\operatorname{tr}\big((\mathbf{XY})^m\big) = 3^m$: the values are $3, 9, 81$. On the other side $\mathbf{Y}^m = 2^{m-1}\mathbf{Y}$, since $\mathbf{Y}^2 = 2\mathbf{Y}$, and $\mathbf{X}^m = \operatorname{diag}(2^m, 1)$, so

$$\operatorname{tr}(\mathbf{X}^m\mathbf{Y}^m) = 2^{m-1}\operatorname{tr}\big(\operatorname{diag}(2^m, 1)\mathbf{Y}\big) = 2^{m-1}(2^m + 1),$$

giving $3, 10, 136$ for $m = 1, 2, 4$.

(b) The inequality $3^m \le 2^{m-1}(2^m + 1)$ holds in all three cases. It is an equality at $m = 1$, as the base case of the induction says it must be, and strict at $m = 2$ $(9 < 10)$ and $m = 4$ $(81 < 136)$.

Exercise B3: Klein with the exponential.

Let $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$ be Hermitian. Use Theorem 20.12.6 with $f(t) = e^t$ to prove

$$\operatorname{tr} e^{\mathbf{A}} \;\ge\; \operatorname{tr} e^{\mathbf{B}} + \operatorname{tr}\big((\mathbf{A} - \mathbf{B})e^{\mathbf{B}}\big),$$

and check the inequality for $\mathbf{A} = \operatorname{diag}(1, 0)$, $\mathbf{B} = \mathbf{0}$.

Solution. The function $f(t) = e^t$ is differentiable on $I = \mathbb{R}$ with $f' = f$, and it is convex by Lemma 17.11.1 (a). Both spectra are real, hence contained in I. So Theorem 20.12.6 gives

$$\operatorname{tr}\big(e^{\mathbf{A}} - e^{\mathbf{B}} - (\mathbf{A} - \mathbf{B})e^{\mathbf{B}}\big) \;\ge\; 0,$$

and the trace is linear (Theorem 0.9.6 (1)), so this rearranges to the stated inequality.

For $\mathbf{A} = \operatorname{diag}(1, 0)$ and $\mathbf{B} = \mathbf{0}$: $\operatorname{tr} e^{\mathbf{A}} = e + 1 \approx 3.71828$, $\operatorname{tr} e^{\mathbf{B}} = \operatorname{tr}\mathbf{I} = 2$, and $\operatorname{tr}(\mathbf{A}e^{\mathbf{0}}) = \operatorname{tr}\mathbf{A} = 1$. So the inequality reads $3.71828 \ge 3$, and it is strict.

20.12.8.3 C. Going deeper

Exercise C1: Two out of three is enough.

Let $\mathbf{A}, \mathbf{B}, \mathbf{C} \in M_n(\mathbb{C})$ be Hermitian. Prove that

$$\operatorname{tr} e^{\mathbf{A}+\mathbf{B}+\mathbf{C}} \;\le\; \operatorname{tr}\!\left(e^{\mathbf{A}} e^{\mathbf{B}} e^{\mathbf{C}}\right)$$

holds whenever **some two** of the three matrices commute, treating the three cases separately. Explain why this does not contradict Example (The three-matrix version fails).

Hint: Theorem 9.9.4 (d), and the cyclic invariance of the trace.

Solution. Case 1: $\mathbf{BC} = \mathbf{CB}$. Then $e^{\mathbf{B}}e^{\mathbf{C}} = e^{\mathbf{B}+\mathbf{C}}$ by Theorem 9.9.4 (d), so $\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}}) = \operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}+\mathbf{C}})$. Since $\mathbf{B}+\mathbf{C}$ is Hermitian, Theorem 20.12.4 applied to the pair $\mathbf{A}, \mathbf{B}+\mathbf{C}$ gives $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}+\mathbf{C}} \le \operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}+\mathbf{C}})$, as required.

Case 2: $\mathbf{AB} = \mathbf{BA}$. Then $e^{\mathbf{A}}e^{\mathbf{B}} = e^{\mathbf{A}+\mathbf{B}}$, so $\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}}) = \operatorname{tr}(e^{\mathbf{A}+\mathbf{B}}e^{\mathbf{C}})$, and Theorem 20.12.4 applied to $\mathbf{A}+\mathbf{B}$ and $\mathbf{C}$ finishes.

Case 3: $\mathbf{AC} = \mathbf{CA}$. By Theorem 0.9.6 (3), $\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}}e^{\mathbf{C}}) = \operatorname{tr}(e^{\mathbf{C}}e^{\mathbf{A}}e^{\mathbf{B}}) = \operatorname{tr}(e^{\mathbf{A}+\mathbf{C}}e^{\mathbf{B}})$, the last step because $\mathbf{A}$ and $\mathbf{C}$ commute. Now Theorem 20.12.4 applied to $\mathbf{A}+\mathbf{C}$ and $\mathbf{B}$ gives $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}+\mathbf{C}} \le \operatorname{tr}(e^{\mathbf{A}+\mathbf{C}}e^{\mathbf{B}})$.

There is no contradiction: in Example (The three-matrix version fails) no two of $\mathbf{P}_1, \mathbf{P}_2, \mathbf{P}_3$ commute. Indeed, suppose two orthogonal projections $\mathbf{P}, \mathbf{Q}$ onto distinct lines commute. Then $\mathbf{PQ}$ is Hermitian, since $(\mathbf{PQ})^* = \mathbf{QP} = \mathbf{PQ}$, and idempotent, since $\mathbf{PQPQ} = \mathbf{P}^2\mathbf{Q}^2 = \mathbf{PQ}$; so it is an orthogonal projection, and its image lies in the image of $\mathbf{P}$ and in that of $\mathbf{Q}$, which meet only in $\mathbf{0}$. Hence $\mathbf{PQ} = \mathbf{0}$, which for $\mathbf{P} = \mathbf{u}\mathbf{u}^{\top}$ and $\mathbf{Q} = \mathbf{w}\mathbf{w}^{\top}$ says $\mathbf{u} \cdot \mathbf{w} = 0$. But the three unit vectors above pair to $-\tfrac{1}{2}$, never 0. For instance $\mathbf{P}_1\mathbf{P}_2 = \tfrac{1}{4}\begin{pmatrix} 1 & -\sqrt{3} \\ 0 & 0 \end{pmatrix} \neq \mathbf{0}$.

Exercise C2: The symmetric Lie formula.

Let $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{C})$.

(a) Prove that $e^{\mathbf{A}+\mathbf{B}} = \lim_{k\to\infty} \left(e^{\mathbf{A}/2k} e^{\mathbf{B}/k} e^{\mathbf{A}/2k}\right)^k$.

(b) Deduce that for Hermitian $\mathbf{A}, \mathbf{B}$ one also has $\operatorname{tr} e^{\mathbf{A}+\mathbf{B}} \le \operatorname{tr}\!\left(e^{\mathbf{A}/2} e^{\mathbf{B}} e^{\mathbf{A}/2}\right)$, and explain why this is not a new inequality.

Hint: for (a), rerun Steps 2–4 of the proof of Lemma 20.12.1 with the new $\mathbf{T}_k$*; only the constant* M *changes.*

Solution.

(a) Keep $\mathbf{S}_k = e^{(\mathbf{A}+\mathbf{B})/k}$ and set $\mathbf{T}_k = e^{\mathbf{A}/2k} e^{\mathbf{B}/k} e^{\mathbf{A}/2k}$. Step 1 of the proof of Lemma 20.12.1 is unchanged: $\mathbf{S}_k^k = e^{\mathbf{A}+\mathbf{B}}$. For Step 2, submultiplicativity and Theorem 15.6.1 (a) give $\|\mathbf{T}_k\|_2 \le e^{a/2k} e^{b/k} e^{a/2k} = e^{c/k}$, the same bound as before, with $a = \|\mathbf{A}\|_2$, $b = \|\mathbf{B}\|_2$, $c = a + b$. For Step 3, write $e^{\mathbf{X}} = \mathbf{I} + \mathbf{X} + \mathbf{R}(\mathbf{X})$ as there and multiply out the three factors. Choosing the $\mathbf{I}$ from all three gives $\mathbf{I}$;

choosing exactly one non-identity term gives $\frac{\mathbf{A}}{2k}+\frac{\mathbf{B}}{k}+\frac{\mathbf{A}}{2k}=\frac{\mathbf{A}+\mathbf{B}}{k}$ together with the three remainders $\mathbf{R}(\frac{\mathbf{A}}{2k})$, $\mathbf{R}(\frac{\mathbf{B}}{k})$, $\mathbf{R}(\frac{\mathbf{A}}{2k})$. Every other term is a product of at least two non-identity factors. Once $k\ge\max(1,c)$, each $\mathbf{R}$ has norm at most $c^2e/(2k^2)$ by Theorem 15.6.1 (c), so every non-identity factor has norm at most K/k with $K=c+c^2e/2$; a product of j of them therefore has norm at most K^j/k^j, which for $2\le j\le 3$ and $k\ge 1$ is at most $\max(K^2,K^3)/k^2$. There are 27 terms in all. Subtracting from $\mathbf{S}_k=\mathbf{I}+\frac{\mathbf{A}+\mathbf{B}}{k}+\mathbf{R}(\frac{\mathbf{A}+\mathbf{B}}{k})$, the $\mathbf{I}$ and the linear terms cancel and what is left is a sum of at most 27 terms, each of norm at most a constant over k^2, so $\|\mathbf{S}_k-\mathbf{T}_k\|_2\le M'/k^2$ for a constant M' depending only on $\mathbf{A}$ and $\mathbf{B}$. Step 4 is verbatim, and yields $\|e^{\mathbf{A}+\mathbf{B}}-\mathbf{T}_k^k\|_2\le e^cM'/k\to 0$.

(b) By Theorem 0.9.6 (3), $\operatorname{tr}\big(e^{\mathbf{A}/2}e^{\mathbf{B}}e^{\mathbf{A}/2}\big)=\operatorname{tr}\big(e^{\mathbf{A}/2}e^{\mathbf{A}/2}e^{\mathbf{B}}\big)=\operatorname{tr}(e^{\mathbf{A}}e^{\mathbf{B}})$, the last step by Theorem 9.9.4 (d) since $\mathbf{A}/2$ commutes with itself. So the two right-hand sides are the same number and the inequality is Theorem 20.12.4 restated. What is new is only the form: the middle expression is a positive semidefinite matrix, being $(e^{\mathbf{A}/2})^*e^{\mathbf{B}}e^{\mathbf{A}/2}$ with $e^{\mathbf{A}/2}$ Hermitian (Proposition 12.1.2 (a)), whereas $e^{\mathbf{A}}e^{\mathbf{B}}$ is not Hermitian. The warning after Example (The inequality on a two-by-two family) shows that the Loewner-order strengthening of this form is nevertheless false.

Exercise C3: When is the relative entropy zero?.

Let $\mathbf{A},\mathbf{B}\in M_n(\mathbb{C})$ be positive definite with $\operatorname{tr}\mathbf{A}=\operatorname{tr}\mathbf{B}=1$.

(a) Show that equality holds in Lemma 20.12.5 for $f(t)=t\log t$ only when $s=t$.

(b) Deduce that $\operatorname{tr}\big(\mathbf{A}(\log\mathbf{A}-\log\mathbf{B})\big)=0$ forces $\mathbf{A}=\mathbf{B}$.

Hint: for (b), look at which coefficients c_{ij} in the proof of Theorem 20.12.6 can be non-zero.

Solution.

(a) By Lemma 20.12.7, $f(t)=t\log t$ is **strictly** convex on $(0,\infty)$. Let $s\ne t$ in $(0,\infty)$ and let $m=\frac12(s+t)$ be their midpoint, which also lies in $(0,\infty)$. Strict convexity gives

$$f(m)<\tfrac12 f(t)+\tfrac12 f(s),$$

while Lemma 20.12.5 applied at the point t with m in place of s gives

$$f(m)\ \ge\ f(t)+f'(t)(m-t)=f(t)+\tfrac12 f'(t)(s-t).$$

Combining and multiplying by 2, $2f(t)+f'(t)(s-t)<f(t)+f(s)$, that is $f(s)>f(t)+f'(t)(s-t)$. So the inequality is strict whenever $s\ne t$.

(b) In the proof of Theorem 20.12.6 with $f(t)=t\log t$, the total is $\sum_{i,j}c_{ij}\big[f(\lambda_i)-f(\mu_j)-f'(\mu_j)(\lambda_i-\mu_j)\big]$, with all $c_{ij}\ge0$ and every bracket ≥0. The computation in Corollary 20.12.8 shows that this total equals $\operatorname{tr}\big(\mathbf{A}(\log\mathbf{A}-\log\mathbf{B})\big)$ when $\operatorname{tr}\mathbf{A}=\operatorname{tr}\mathbf{B}$. If it is 0, then $c_{ij}=0$ whenever the bracket is non-zero, that is, by (a), whenever $\lambda_i\ne\mu_j$.

So $\langle\mathbf{v}_j,\mathbf{u}_i\rangle=0$ whenever $\lambda_i\ne\mu_j$. Fix j and expand $\mathbf{v}_j=\sum_i\langle\mathbf{v}_j,\mathbf{u}_i\rangle\mathbf{u}_i$: only indices i with $\lambda_i=\mu_j$ contribute, so $\mathbf{v}_j$ lies in the eigenspace of $\mathbf{A}$ for the eigenvalue μ_j, giving $\mathbf{A}\mathbf{v}_j=\mu_j\mathbf{v}_j=\mathbf{B}\mathbf{v}_j$. This holds for every j, and the $\mathbf{v}_j$ form a basis, so $\mathbf{A}=\mathbf{B}$.

Chapter 21

Affine and Projective Geometry

Twenty chapters have studied the vector space, and a vector space has an origin. Geometry does not. Nothing a geometer says — these three points are collinear, these two lines are parallel, this point is the midpoint of that segment — mentions a zero vector, and the sets that geometry actually hands us are usually not subspaces at all. Chapter 2's solution set of $\mathbf{Ax} = \mathbf{b}$ with $\mathbf{b} \neq \mathbf{0}$ is the first example in the book: it misses $\mathbf{0}$, the sum of two of its points is not one of its points, and yet it is a perfectly good flat piece of space. Something is being described there that the word "subspace" does not reach.

There are two classical repairs, and this chapter is both of them. **Affine geometry** deletes the origin and keeps what survives: points, differences of points, flats, parallelism, ratios along a line, and the maps that send lines to lines. **Projective geometry** goes the other way and *adds* points — one for every direction — so that two lines in a plane always meet, the dimension formula for a join loses its second case, every quadric in a plane is one of a very short list, and interchanging "point" with "hyperplane" turns every theorem into another theorem.

Everything here is proved with linear algebra, and mostly with the linear algebra of Chapters 1 to 4. An affine space is a vector space acting freely and transitively on a set; a projective space is the set of lines through the origin of a vector space; a projectivity is an invertible linear map read on those lines; a conic is a quadratic form; a line in space is a wedge of two vectors. The geometry is the payoff, not the method.

21.0.1 Conventions

- **Points are not bold.** P, Q, R are points of an affine space $\mathcal{A}$, and $\overrightarrow{PQ} \in V$ is the vector from P to Q; vectors keep the book's bold, $\mathbf{v}$, $\mathbf{x}$. We write $\mathbb{A}^n$ for affine n-space, the set F^n with its origin deliberately forgotten.
- **A flat is an affine subspace**, and $\vec{A}$ is its direction space, a subspace of V. The join $A \vee B$ is the smallest flat containing both, the affine counterpart of $U + W$.
- $\mathbb{P}(V)$ **is the projective space of** V, of dimension $\dim V - 1$, with $\mathbb{P}^n(F) = \mathbb{P}(F^{n+1})$; $[\mathbf{x}] = [x_0 : x_1 : \cdots : x_n]$ is the point determined by $\mathbf{x} \neq \mathbf{0}$. The empty projective space has dimension -1, and that convention is used, not merely tolerated. The projective linear group is $\mathrm{PGL}(V)$.
- **The cross-ratio** $(A, B; C, D)$ **is a point of** $\mathbb{P}^1(F)$, not a scalar. Over a field where the affine chart applies it is the familiar number, and Section 7 gives the formula; keeping it projective is what lets it take the value $[1 : 0]$ without apology.

- V^* **is Chapter 4's dual space** and $\mathbb{P}(V^*)$ the dual projective space, whose points are the hyperplanes of $\mathbb{P}(V)$. Section 8 writes S^0 for the subspace of $\mathbb{P}(V^*)$ dual to S, built from the annihilator.
- $Z(q)$ **is the zero set of a quadratic form**, and "conic" means $Z(q)$ in a projective plane. Section 5's affine quadric is instead the zero set of a degree-two polynomial $\mathbf{x}^\top\mathbf{A}\mathbf{x}+2\mathbf{b}^\top\mathbf{x}+c$, and carries the $(n+1)\times(n+1)$ matrix $\widetilde{\mathbf{A}}$ alongside the small matrix $\mathbf{A}$.

21.0.1.1 Which field, and where the characteristic bites

Sections 1, 2, 6, 7, 8 and 9 work over an **arbitrary field** F, with no hypothesis on the characteristic at all. That includes the chapter's finite-field computations: the four-point affine plane over $\mathbb{F}_2$ in Section 1, and the count of $\mathbb{P}^n(\mathbb{F}_q)$ with the Fano plane in Section 6.

Characteristic 2 is barred exactly where quadratic forms appear, which is Section 5 throughout and Section 10 up to the Plücker material. The reason is Chapter 13's: over $\mathbb{F}_2$ a quadratic form is not determined by a symmetric matrix, and Section 5 opens by showing that there is then nothing left to classify — every $\mathbf{x}^\top\mathbf{A}\mathbf{x}$ with $\mathbf{A}$ symmetric collapses to the square of a linear form. Section 5 names the hypothesis at each of the three places it does work, and Section 10 states it at the head and lifts it explicitly for the Plücker subsection, which needs no assumption on F. Two smaller restrictions are local and flagged where they occur: Section 2's centroid needs $3 \neq 0$ as well as $2 \neq 0$, and over $\mathbb{F}_3$ the three medians really are parallel; Section 7's negative result about $n+1$ points needs F to have at least three elements, and Section 7 proves that over $\mathbb{F}_2$ the negative result is false.

Three sections are metric, and they are over $\mathbb{R}$ with the standard inner product: Section 4 entirely, the second half of Section 5, and Section 3, which inherits Chapter 17's setting of $\mathbb{R}^n$ with the dot product. Everywhere else a distance would be meaningless: a projectivity does not preserve one.

21.0.2 What the chapter quotes, and what it does not prove

The chapter imports no analysis. It develops none of its own — no limits, no continuity, no compactness argument — and it adds nothing to the list of analytic facts **(A1)**–**(A6)** that Chapter 15 introduced. It uses that list exactly once, at one remove: Section 3's proof that a bounded polyhedron is the hull of its vertices cites Chapter 15's Corollary 15.2.5 to supply the compactness hypothesis of Chapter 17's Theorem 17.8.5. That is the whole of it. Section 3 says so at its head, and uses the words "closed", "bounded" and "compact" only inside the results it cites.

Topology is likewise absent. $\mathbb{P}^2(\mathbb{R})$ is a famous topological object, and a reader who has met it will expect the words "compact" and "non-orientable"; Section 6 says plainly that this chapter does not use them, because every argument here is a statement about subspaces of a vector space, valid over any field, including finite ones where topology has nothing to say.

Six things are quoted and not proved. Each is flagged again where it appears, and **nothing in the chapter rests on any of them.**

- **Section 9** — the coordinatization theory of axiomatic projective planes: that Desargues's theorem holds in a plane exactly when the plane comes from a division ring, that Pappus's theorem holds exactly when that ring is commutative, that Pappus therefore implies

Desargues, and that non-Desarguesian planes exist. This book has built neither division rings nor synthetic planes, and "projective plane" has meant $\mathbb{P}(V)$ throughout. Section 9 states these with credit in one remark and proves Desargues and Pappus itself, over an arbitrary field, by linear algebra.

- **Section 8** — the duality principle is claimed as a **working method, not a meta-theorem**. What Section 8 proves is a list of five equivalences about the correspondence $S \mapsto S^0$; to turn "every incidence statement has a dual" into a theorem one has to define a formal language and induct on it, which this book has not set up. So every dual statement the chapter uses is proved individually, and Section 8 says this in as many words.
- **Section 4** — the classification of motions is proved in full for $\mathbb{R}^2$ and $\mathbb{R}^3$, both the direct and the opposite cases. The general shape in $\mathbb{R}^n$ — a translation along a flat together with mutually orthogonal rotation planes — is described in a warning and is **not** proved; the warning says so, and gives $\mathbf{R}_{\pi/2} \oplus \mathbf{R}_{\pi/3}$ in $\mathbb{R}^4$ as the witness that the three-dimensional list does not extend.
- **Section 3** — that a dual variable is the *exact* rate at which the optimal value gains when a constraint is loosened. Section 3 proves the inequality, that y_i **bounds** the gain, and then exhibits a two-row program where the exact reading fails. It also declines to develop the finite description of an unbounded polyhedron as a polytope plus a cone, pointing at Chapter 17's exercise instead.
- **Section 10** — *which* quadric the Klein quadric is. The main text records that it is smooth, with inertia $(3, 3, 0)$ over $\mathbb{R}$; the Gram matrix that shows this is computed in Exercise (C2: The Klein quadric), and nothing in the section rests on the answer.
- **Section 10** — which proportionality factors turn the parametrization of the circle into *primitive* Pythagorean triples. That is arithmetic about parities and common factors, not linear algebra, and Section 10 says so where it stops.

Two exercises from earlier chapters are cited, both **for credit only**: Chapter 14 §10's Exercise (C1: The Plücker relation), which reaches the Plücker relation by the $\omega \wedge \omega$ route, and Chapter 17 §09's Exercise (C1: Unbounded polyhedra). Section 10 proves the Plücker relation in both directions from results in the text, and its proof needs no hypothesis on the characteristic, which the exercise's route does. No theorem here rests on an exercise.

One debt is paid. Chapter 14 §08 hinted at Plücker coordinates without naming the chapter that would build them; Section 10 does.

21.0.3 What you need

The chapter leans hard on Chapters 0 to 4 and on Chapters 11, 13 and 17, and lightly on everything else. **Chapters 8, 9, 12, 18, 19 and 20 are not used at all.** Eigenvalues appear only through Chapter 11's spectral theorem and Chapter 13's inertia; no canonical form of an operator, no positive semidefinite matrix, no singular value and no matrix inequality is needed anywhere.

- **Chapter 0** — sets, maps and the algebra the constructions rest on: functions and their inverses for Section 4, equivalence relations and quotient sets for Section 6's construction of $\mathbb{P}(V)$, the characteristic of a field for Section 5, and the group axioms, which the affine, Euclidean and projective groups each verify: Theorem 0.4.7, Theorem 0.4.2, Definition 0.5.2, Definition 0.5.5, Theorem 0.5.2, Definition 0.7.2, Theorem 0.9.3, Theorem 0.9.2, Definition 0.10.1, Definition 0.10.2, Definition 0.10.3, Example (Groups), Theorem 0.10.1, Theorem 0.10.3.
- **Chapter 1** — the chapter's constant companion, and above all the dimension formula

for a sum of subspaces, which is what both the affine join formula and the projective dimension formula reduce to: Theorem 1.2.1, Theorem 1.2.2, Theorem 1.3.1, Definition 1.4.1, Lemma 1.5.3, Theorem 1.5.1, Theorem 1.6.5, Theorem 1.6.8, Theorem 1.6.4, Theorem 1.6.3, Theorem 1.7.1, Theorem 1.7.4, Theorem 1.7.3, Theorem 1.8.2.

- **Chapter 2** — the object that opens Section 1, the solution set of a system with $\mathbf{b} \neq \mathbf{0}$; the rank facts Sections 2, 3 and 10 count with; and the observation that a homogeneous system with more unknowns than equations has a non-trivial solution, which is the whole existence half of "five points determine a conic": Theorem 2.1.1, Theorem 2.1.3, Corollary 2.2.5, Theorem 2.4.4, Theorem 2.5.7, Theorem 2.5.8, Theorem 2.5.5, Lemma 2.7.2.
- **Chapter 3** — linear maps, which are the linear parts of affine maps and the representatives of projectivities, together with the cosets that flats turn out to be: Example (Translation), Theorem 3.1.6, Theorem 3.1.5, Theorem 3.2.1, Theorem 3.2.2, Theorem 3.2.3, Theorem 3.2.5, Theorem 3.2.4, Theorem 3.3.1, Corollary 3.3.2, Theorem 3.4.2, Theorem 3.5.1, Theorem 3.5.7, Theorem 3.5.3, Theorem 3.5.4, Corollary 3.5.5, Theorem 3.6.5, Definition 3.9.2, Lemma 3.9.3, Theorem 3.9.5, Theorem 3.10.1.
- **Chapter 4** — the whole of Section 8 and half of Sections 2 and 6. The annihilator is what makes projective duality a bijection, and the hyperplane-as-kernel-of-a-functional is what makes a flat a solution set: Definition 4.1.2, Theorem 4.1.3, Theorem 4.1.1, Proposition 4.1.2, Corollary 4.1.4, Definition 4.2.1, Theorem 4.2.3, Theorem 4.2.2, Corollary 4.3.4, Corollary 4.3.5, Theorem 4.3.2, Definition 4.4.1, Theorem 4.4.1, Definition 4.5.2, Theorem 4.5.3, Theorem 4.6.2, Lemma 4.6.1, Corollary 4.6.6, Proposition 4.6.4, Example (Equations for a plane in $\mathbb{R}^4$).
- **Chapter 5 §01** — one fact: a non-zero polynomial of degree at most d over a field has at most d roots, which is how Section 5 knows that a line meeting a quadric in three points lies inside it. Section 10 uses Chapter 2 §07's version of the same bound for the same purpose: Corollary 5.1.4.
- **Chapter 6** — determinants, for the direct-or-opposite dichotomy of Section 4 and for the coordinate computations; the Vandermonde determinant is how Section 7 certifies a list of points in general position: Corollary 6.3.3, Theorem 6.4.5, Theorem 6.5.4, Theorem 6.5.2, Theorem 6.8.1, Corollary 6.8.2, Theorem 6.10.3.
- **Chapter 7 §01** — block multiplication, which is what the $(n+1) \times (n+1)$ matrix of an affine map is for: Theorem 7.1.1.
- **Chapter 10** — the Euclidean sections' toolkit: the inner product and Cauchy–Schwarz, orthogonal decomposition, the characterizations of an isometry, and the polarization identity that turns distance-preservation into linearity: Theorem 10.1.5, Theorem 10.1.2, Theorem 10.2.1, Corollary 10.2.3, Theorem 10.3.2, Theorem 10.6.5, Lemma 10.7.2, Theorem 10.7.3, Proposition 10.7.4, Theorem 10.7.5, Definition 10.8.1, Proposition 10.8.2.
- **Chapter 11** — the real spectral theorem, which rotates a quadric onto its principal axes, and the canonical form of an orthogonal matrix, which is the entire engine of Section 4's two classification theorems: Corollary 11.5.2, Theorem 11.5.5, Example (Finding the axes of a conic), Theorem 11.6.1, Corollary 11.6.2, Theorem 11.6.4, Theorem 11.6.5, Theorem 11.6.7.
- **Chapter 13** — the classification of quadratic forms, which Sections 5 and 10 turn into the classification of quadrics. Congruence is what an affine change of coordinates does to the big matrix, and Sylvester's law is what separates an ellipse from an empty set: Definition 13.1.2, Proposition 13.1.2, Definition 13.2.1, Proposition 13.2.2, Proposition 13.2.4, Theorem 13.2.3, Definition 13.3.2, Theorem 13.3.5, Theorem 13.3.3, Proposition 13.3.2, Theorem 13.4.2, Proposition 13.4.3, Corollary 13.4.4, Theorem 13.5.1, Corollary 13.5.2, Definition 13.5.1, Theorem 13.5.3, Definition 13.7.1, Corollary 13.9.3, Example (The Pfaffian in Sizes 2 and 4).
- **Chapter 14 §§08–10** — exterior powers, for Plücker coordinates alone: the basis of $\Lambda^2 F^4$, that a wedge is non-zero exactly when the factors are independent, and that its coordi-

nates are the minors: Lemma 14.8.1, Theorem 14.8.5, Theorem 14.8.7, Corollary 14.8.6, Theorem 14.9.5, Exercise (C1: The Plücker relation) (credited, not used).

- **Chapter 15** — two facts, both in the metric sections: the reverse triangle inequality for Section 4's non-example, and the compactness of closed bounded sets, which is the chapter's only contact with analysis: Lemma 15.1.1, Corollary 15.2.5.
- **Chapter 16** — the Rayleigh quotient, which reads Section 5's semi-axes off the eigenvalues, and the inertia triple: Proposition 16.1.1, Definition 16.10.1.
- **Chapter 17** — all of Section 3, and the affine vocabulary of Sections 1, 2 and 5. Convex hulls and affine hulls, separation, extreme points and faces, polytopes and Minkowski–Weyl, and linear programming duality: Definition 17.1.5, Proposition 17.1.4, Theorem 17.1.3, Proposition 17.1.1, Definition 17.1.2, Definition 17.2.1, Lemma 17.2.1, Theorem 17.3.6, Definition 17.6.2, Theorem 17.6.1, Theorem 17.6.3, Corollary 17.6.2, Theorem 17.6.5, Definition 17.8.1, Definition 17.8.2, Proposition 17.8.4, Lemma 17.8.3, Theorem 17.8.5, Corollary 17.8.6, Definition 17.9.2, Proposition 17.9.1, Theorem 17.9.5, Theorem 17.9.2, Corollary 17.9.3, Example (The cube and the cross-polytope), Exercise (C1: Unbounded polyhedra) (pointed at, not used).

21.0.4 Roadmap

- **Affine Spaces and Affine Maps.** A set on which a vector space acts freely and transitively: differences of points are vectors, sums of points are meaningless, and Chasles's relation is the one law. Choosing an origin identifies the space with V, and the identification is canonical only after the choice. Affine combinations are exactly the combinations whose coefficients sum to 1, and no other coefficient sum survives a change of origin. An affine map is a linear map plus a translation, for a unique linear part, and the whole affine group fits in one $(n+1) \times (n+1)$ block matrix — the device the rest of the chapter computes with.
- **Flats, Independence and Coordinates.** Flats are the cosets, parallelism is an equivalence relation on flats of equal dimension, and two flats either meet or lie in two distinct parallel hyperplanes. The dimension of a join has two cases: the subspace formula when they meet, and a corrected formula with a $+1$ when they miss, in which the intersection of **directions** takes over. No convention for $\dim \emptyset$ merges the two. Then affine frames, barycentric coordinates, and an affine map pinned down by its values on an affine frame of $n+1$ points; on any set lying inside a proper flat — in particular on any n points — two distinct affine maps agree. The medians of a triangle meet at the centroid, in one line of barycentric coordinates — and over $\mathbb{F}_3$ they do not meet at all.
- **Convex Polyhedra, Geometrically.** A reading of Chapter 17, not a reproof: it says so in its first paragraph. A face is what a supporting hyperplane cuts out; faces are polyhedra and there are finitely many; vertex, extreme point and basic feasible solution are three names for one thing. The face lattices of a cube and of a simplex are computed in full. A linear program is a family of parallel hyperplanes sweeping across a solid, the optimal set is a whole face, and the dual variables are the non-negative weights expressing the objective as a combination of the active outer normals. Negative cases: an unbounded slab with no vertex at all, whose optimum is nonetheless attained on a face that contains none, and a quadrant that has a vertex and no optimum. No algorithm appears here or anywhere in this book; Chapter 23 is where algorithms live.
- **Euclidean Motions.** Distance alone forces everything: a map of $\mathbb{R}^n$ preserving distances is affine with orthogonal linear part, and **surjectivity is not assumed** — it is proved. Polarization is the move, and the Euclidean norm is doing real work, as a distance-preserving non-affine map for the maximum norm shows. Motions form a group with the translations

normal in it and the orthogonal group as the quotient's content, recorded without quotient groups, which this book has not built. Then both classifications in full: in the plane, translation, rotation, reflection, glide reflection; in space, translation, rotation, screw, reflection, glide, rotatory reflection, told apart by the fixed set. From $\mathbb{R}^4$ on the list breaks, and the section says so.

- **Affine and Euclidean Quadrics.** A quadric is a quadratic form that has forgotten where the origin is. An affine substitution acts on the $(n+1)\times(n+1)$ matrix by congruence, a center exists exactly when the linear vector lies in the column space of the small matrix, and the parabola is precisely the centerless case. Over $\mathbb{R}$ every quadric is affinely equivalent to exactly one of three families, separated by the pair of inertias; for $n=2$ that is nine normal forms, two of which have empty zero sets and are still inequivalent, and for $n=3$ it is seventeen. Allowing only motions instead keeps the eigenvalues, and they are the reciprocal squared semi-axes — the Rayleigh quotient read on an ellipsoid.
- **Projective Space.** Stop working with the points of a vector space and start working with its lines through the origin. The affine chart splits $\mathbb{P}^n(F)$ into a copy of $\mathbb{A}^n$ and a hyperplane at infinity of directions, and the two parallel lines of the opening now meet, at a point whose coordinates are computed. The dimension formula $\dim(S\vee T)+\dim(S\cap T)=\dim S+\dim T$ has **no exceptional case**, which is the whole reason for the construction; two distinct lines of a projective plane meet in exactly one point. Finite fields give $|\mathbb{P}^n(\mathbb{F}_q)|=(q^{n+1}-1)/(q-1)$, and the Fano plane is drawn and checked.
- **Projective Transformations.** An invertible linear map descends to $\mathbb{P}(V)$, and two of them give the same projectivity exactly when they differ by a non-zero scalar — so $\mathrm{PGL}(V)$ is $\mathrm{GL}(V)$ modulo scalars, said without quotient groups. The fundamental theorem: $n+2$ points in general position can be carried to any other such list by exactly one projectivity. $n+1$ points are not enough, and the explicit failure is a diagonal matrix; over $\mathbb{F}_2$, and only there, $n+1$ points do suffice, which is proved. Then the cross-ratio, invariant under projectivities and a complete invariant of four points on a line, computed exactly; perspectivities; and the sentence that ties the chapter together — affine maps are exactly the projectivities fixing the hyperplane at infinity as a set.
- **Duality.** A point of $\mathbb{P}(V^*)$ is a hyperplane of $\mathbb{P}(V)$. The annihilator gives an inclusion-reversing bijection $S\mapsto S^0$ between the projective subspaces of the two spaces, with $\dim S^0=n-1-\dim S$, exchanging joins with meets and the two extreme subspaces with each other. Dualizing twice returns the original. The duality principle is then stated as five equivalences and used as a recipe, each application being its own proof; "two distinct points lie on a unique line" dualizes to "two distinct lines meet in a unique point", and the projective dimension formula turns out to be self-dual. The trap is spelled out: the dual of "point" is "hyperplane", and in $\mathbb{P}^3$ two lines need not meet.
- **Desargues and Pappus.** Two triangles are perspective from a point if and only if they are perspective from a line, proved inside $\mathbb{P}^2$ by choosing representatives so that the hypothesis reads $\mathbf{a}'=\mathbf{a}+\mathbf{o}$, with every scaling step verified — that is where such proofs go wrong. The converse costs no second theorem: the same lemma, applied to a pair of auxiliary triangles built out of the same picture. Pappus follows in coordinates, with the frame chosen by the previous section's fundamental theorem to make the computation short, and the degenerate configurations excluded by hypothesis. Both hold over every field, and the remark that closes the section records, with credit and without proof, that Desargues means "division ring" and Pappus means "commutative".
- **Conics and Lines in Space.** Over an algebraically closed field a projective quadric is classified by rank alone; over $\mathbb{R}$ by rank and inertia up to sign, giving five conics in $\mathbb{P}^2(\mathbb{R})$: empty, a point, a line, two lines, a smooth conic. Five points in general position lie on exactly one conic, and the independence of the five conditions is proved, not assumed. A smooth conic with one point is in bijection with $\mathbb{P}^1$ by projection from that point, which

turns one Pythagorean triple into all of them. Pole, polar and the dual conic use Section 8's duality. Finally Plücker coordinates, over any field: a line of $\mathbb{P}^3$ is a point of $\mathbb{P}^5$, the six coordinates satisfy $p_{01}p_{23} - p_{02}p_{13} + p_{03}p_{12} = 0$, and **every** point of that Klein quadric is a line — both directions proved. A summary closes the chapter.

21.0.5 Named moves

- **Choose an origin, then say that you chose it.** An affine space becomes a vector space the moment a point is picked, and every affine statement is then a linear statement about the difference vectors. The discipline is to record which conclusions survive a different choice: those are the affine ones, and the coefficient sum 1 is exactly the test.
- **Add a coordinate to linearize.** An affine map of F^n is not linear, but $\mathbf{x} \mapsto (1, \mathbf{x})$ — Section 1 writes the extra coordinate last instead — makes it the restriction of a linear map of F^{n+1}, with matrix $\left(\begin{smallmatrix} 1 & \mathbf{0}^\top \\ \mathbf{b} & \mathbf{M} \end{smallmatrix}\right)$. The same extra coordinate is what turns a quadric polynomial into a quadratic form and an affine space into a chart of a projective space. Three of this chapter's theorems are that one observation in three costumes.
- **Pass from points to lines through the origin.** Scaling is the enemy of a well-defined point and the friend of a well-defined condition: $q(\lambda\mathbf{x}) = \lambda^2 q(\mathbf{x})$ vanishes when $q(\mathbf{x})$ does. Anything homogeneous descends to $\mathbb{P}(V)$, which is why every object in the second half of the chapter is the solution set of homogeneous polynomial equations.
- **Choose the representatives so the hypothesis becomes an equation.** A projective point is a whole line of vectors, and the content of most projective proofs is the scaling chosen at the start: $\mathbf{a}' = \mathbf{a} + \mathbf{o}$ in Desargues, a normalized frame in the fundamental theorem, the second intersection point in the conic parametrization. State out loud which scalings remain free afterwards.
- **Split the translation and ask what $\mathbf{I}-\mathbf{Q}$ can absorb.** To classify a map $\mathbf{x} \mapsto \mathbf{Q}\mathbf{x}+\mathbf{b}$, decompose $\mathbf{b}$ along the kernel of $\mathbf{I} - \mathbf{Q}$ and its complement. The part in the image is absorbed by moving the fixed set; the part in the kernel survives and is the glide. That single question produces both of Section 4's classification theorems.
- **Read an old theorem geometrically instead of proving a new one.** Section 3 adds no convexity theorem to Chapter 17. It renames the objects — face, vertex, edge, facet — and the theorems become statements about a solid with flat sides. Knowing when a chapter is a translation rather than a construction is worth as much as the construction.
- **Count the conditions, then prove they are independent.** Five points impose five linear conditions on a 6-dimensional space of forms, so a conic exists by counting alone. Uniqueness is the real theorem, and it is where general position earns its keep: a second independent solution would let us push a conic through a sixth point on one of the lines, a conic meeting a line three times contains it, so it splits into two lines, and the second line then carries three of the original five. The count is cheap; the independence is the content.
- **Dualize by the dimension formula, never by the words.** The dual of a d-dimensional subspace has dimension $n-1-d$. Compute that number before translating any statement: in a plane it sends points to lines, but in $\mathbb{P}^3$ it sends points to planes and lines to lines, and translating "point" to "line" there produces a false theorem.

21.1 Affine Spaces and Affine Maps

Every space in this book so far has had a distinguished point: the zero vector. Geometry does not. A plane drawn on paper has no privileged spot, and none of the statements a geometer

cares about — three points are collinear, two lines are parallel, this point is the midpoint of that segment — mentions one. This section builds the object that has all the structure of a vector space except the origin, and the maps between such objects. Everything in the rest of the chapter is written in this language.

21.1.1 A set with no zero in it

Chapter 2 already produced such an object without naming it. Let $\mathbf{A} \in M_{m\times n}(F)$ and $\mathbf{b} \in F^m$, and suppose $\mathbf{Ax} = \mathbf{b}$ is consistent. By Theorem 2.1.3 the solution set is $\mathbf{p}+N$, where $N = \mathrm{nul}(\mathbf{A})$ and $\mathbf{p}$ is any one solution. When $\mathbf{b} \neq \mathbf{0}$ this set is **not** a subspace: it misses $\mathbf{0}$, and the sum of two solutions is not a solution. Yet it is not shapeless either. The difference of two solutions is a vector of N, and adding a vector of N to a solution gives a solution. So the solution set carries an action of N, and N records exactly how any two solutions differ.

That is the whole structure, and it deserves a name. The only operation is: *subtract two points and get a vector; add a vector to a point and get a point.* Adding two points is meaningless, and so is multiplying a point by a scalar.

An affine space is a set of points in which differences of points are vectors, and every vector moves every point to exactly one other.

Definition 21.1.1 — Affine Space

Let V be a vector space over a field F. An **affine space with direction space** V is a **non-empty** set $\mathcal{A}$, whose elements are called **points**, together with a map

$$\mathcal{A} \times \mathcal{A} \to V, \qquad (P, Q) \mapsto \overrightarrow{PQ},$$

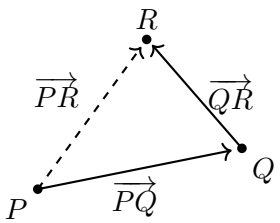
such that:

(AS1) (**Chasles's relation**) $\overrightarrow{PQ} + \overrightarrow{QR} = \overrightarrow{PR}$ **for all** $P, Q, R \in \mathcal{A}$;

(AS2) **for every** $P \in \mathcal{A}$, the map $\mathcal{A} \to V$, $Q \mapsto \overrightarrow{PQ}$, is a **bijection**.

The **dimension** of $\mathcal{A}$ is $\dim \mathcal{A} := \dim V$. For $P \in \mathcal{A}$ and $\mathbf{v} \in V$ we write $P + \mathbf{v}$ for the unique point Q with $\overrightarrow{PQ} = \mathbf{v}$, which exists and is unique by (AS2).

Read the two clauses. (AS1) says that traveling from P to Q and then from Q to R is traveling from P to R; it is the one law that makes the arrows behave like displacements. (AS2) says that from any fixed point P, every vector of V is the displacement to exactly one point: **existence** makes $\mathcal{A}$ big enough (the action is *transitive*), **uniqueness** makes it no bigger (the action is *free*). The set $\mathcal{A}$ is not a vector space and has no zero; V is a vector space and has one.



Two consequences are immediate and will be used constantly.

Lemma 21.1.1 — First consequences of Chasles

Let $\mathcal{A}$ be an affine space with direction space V. For all $P, Q \in \mathcal{A}$ and $\mathbf{u}, \mathbf{w} \in V$:

(a) $\overrightarrow{PP} = \mathbf{0}$, and $\overrightarrow{QP} = -\overrightarrow{PQ}$;
(b) $P + \mathbf{0} = P$ and $(P + \mathbf{u}) + \mathbf{w} = P + (\mathbf{u} + \mathbf{w})$;
(c) $\overrightarrow{PQ} = \mathbf{0}$ if and only if $P = Q$.

Proof.

(a) Taking $P = Q = R$ in (AS1) gives $\overrightarrow{PP} + \overrightarrow{PP} = \overrightarrow{PP}$, so $\overrightarrow{PP} = \mathbf{0}$ by cancellation in the group $(V, +)$ (Theorem 0.10.1). Taking $R = P$ in (AS1) gives $\overrightarrow{PQ} + \overrightarrow{QP} = \overrightarrow{PP} = \mathbf{0}$.
(b) $P + \mathbf{0} = P$ restates $\overrightarrow{PP} = \mathbf{0}$. For the second identity, put $Q = P + \mathbf{u}$ and $R = Q + \mathbf{w}$, so that $\overrightarrow{PQ} = \mathbf{u}$ and $\overrightarrow{QR} = \mathbf{w}$. By (AS1), $\overrightarrow{PR} = \mathbf{u} + \mathbf{w}$, which says $R = P + (\mathbf{u} + \mathbf{w})$.
(c) ($\Leftarrow$) is (a). ($\Rightarrow$) If $\overrightarrow{PQ} = \mathbf{0} = \overrightarrow{PP}$, then $Q = P$ by the injectivity in (AS2).

■

The clauses in part (b) are the axioms of an action of the additive group of V on $\mathcal{A}$, and the definition is often given that way instead. The two presentations carry the same information.

Proposition 21.1.2 — The two forms of the definition agree

Let V be a vector space over F and $\mathcal{A}$ a non-empty set. Giving a map $\mathcal{A} \times \mathcal{A} \to V$ satisfying (AS1) and (AS2) is the same as giving a map $\mathcal{A} \times V \to \mathcal{A}$, written $(P, \mathbf{v}) \mapsto P + \mathbf{v}$, such that

(AC1) $P + \mathbf{0} = P$ for every $P \in \mathcal{A}$;
(AC2) $(P + \mathbf{u}) + \mathbf{w} = P + (\mathbf{u} + \mathbf{w})$ for all $P \in \mathcal{A}$ and $\mathbf{u}, \mathbf{w} \in V$;
(AC3) for all $P, Q \in \mathcal{A}$ there is **exactly one** $\mathbf{v} \in V$ with $P + \mathbf{v} = Q$.

The two constructions are inverse to each other.

Idea. There is nothing to find: in one direction the addition was already defined after Definition 21.1.1, in the other the vector $\overrightarrow{PQ}$ is the one whose uniqueness (AC3) asserts. The work is checking the axioms, and each check is one line.

Proof. Suppose first that $(P, Q) \mapsto \overrightarrow{PQ}$ satisfies (AS1) and (AS2), and define $P + \mathbf{v}$ as after Definition 21.1.1. Then (AC1) and (AC2) are Lemma 21.1.1 (b), and (AC3) is (AS2), since $P + \mathbf{v} = Q$ says $\overrightarrow{PQ} = \mathbf{v}$.

Conversely, suppose $(P, \mathbf{v}) \mapsto P + \mathbf{v}$ satisfies (AC1)–(AC3), and let $\overrightarrow{PQ}$ be the unique $\mathbf{v}$

with $P+\mathbf{v}=Q$. For (AS1), put $\mathbf{u}=\overrightarrow{PQ}$ and $\mathbf{w}=\overrightarrow{QR}$; then by (AC2),

$$P+(\mathbf{u}+\mathbf{w})=(P+\mathbf{u})+\mathbf{w}=Q+\mathbf{w}=R,$$

so $\overrightarrow{PR}=\mathbf{u}+\mathbf{w}$ by the uniqueness in (AC3). For (AS2), fix P. The map $Q\mapsto\overrightarrow{PQ}$ is surjective because $\mathbf{v}$ is the image of $P+\mathbf{v}$, and injective because $\overrightarrow{PQ}=\overrightarrow{PQ'}=\mathbf{v}$ gives $Q=P+\mathbf{v}=Q'$.

The two passages are inverse: starting from $\overrightarrow{\cdot}$, the constructed addition has $P+\mathbf{v}=Q$ exactly when $\overrightarrow{PQ}=\mathbf{v}$, so the difference map it returns is the original one; and starting from an addition, the same equivalence returns it unchanged. This proves the proposition.

■

Remark. The converse half used only (AC2) and (AC3), and it could not have used more: (AC1) follows from the other two. Indeed (AC3) with $Q=P$ gives exactly one $\mathbf{v}$ with $P+\mathbf{v}=P$, and that $\mathbf{v}$ has $P+(\mathbf{v}+\mathbf{v})=(P+\mathbf{v})+\mathbf{v}=P+\mathbf{v}=P$ by (AC2), so $\mathbf{v}+\mathbf{v}=\mathbf{v}$ by the same uniqueness and $\mathbf{v}=\mathbf{0}$. We list (AC1) anyway, because that is how the axioms of a group action are usually written.

Now the examples. The first is the one every other example is modeled on.

Example. (Four affine spaces)

Check each of the following against Definition 21.1.1, and say what its direction space and dimension are.

(a) A vector space V over F, with $\overrightarrow{\mathbf{xy}}:=\mathbf{y}-\mathbf{x}$.

(b) A coset $\mathbf{p}+U$ of a subspace U of V (Definition 3.9.2), with the same difference map.

(c) The solution set of a **consistent** system $\mathbf{Ax}=\mathbf{b}$, $\mathbf{A}\in M_{m\times n}(F)$.

(d) The set $\mathbb{F}_2^2$ of four points, with $\overrightarrow{\mathbf{xy}}=\mathbf{y}-\mathbf{x}$.

Solution.

(a) Chasles reads $(\mathbf{y}-\mathbf{x})+(\mathbf{z}-\mathbf{y})=\mathbf{z}-\mathbf{x}$, which is true in any vector space. For fixed $\mathbf{x}$, the map $\mathbf{y}\mapsto\mathbf{y}-\mathbf{x}$ is a bijection $V\to V$ with inverse $\mathbf{v}\mapsto\mathbf{x}+\mathbf{v}$. Direction space V; dimension $\dim V$. Here the point $\mathbf{x}$ and the vector $\mathbf{x}$ are the same object, and only the language distinguishes them.

(b) The set $\mathbf{p}+U$ is non-empty (it contains $\mathbf{p}$) and the difference of two of its elements is $(\mathbf{p}+\mathbf{u})-(\mathbf{p}+\mathbf{w})=\mathbf{u}-\mathbf{w}\in U$, so the map does land in U. Chasles is again the identity in (a). For fixed $\mathbf{x}\in\mathbf{p}+U$, the map $\mathbf{y}\mapsto\mathbf{y}-\mathbf{x}$ is a bijection $\mathbf{p}+U\to U$: it is injective, and $\mathbf{u}\in U$ is the image of $\mathbf{x}+\mathbf{u}$, which lies in $\mathbf{p}+U$ because U is closed under addition. Direction space U; dimension $\dim U$. Over $\mathbb{R}$ these are exactly Chapter 17's affine subspaces of V (Definition 17.1.5 (b)), with the same dimension.

(c) By Theorem 2.1.3 the solution set is $\mathbf{p}+\operatorname{nul}(\mathbf{A})$ for any one solution $\mathbf{p}$, so this is a special case of (b). Direction space $\operatorname{nul}(\mathbf{A})$; dimension $\operatorname{nullity}(\mathbf{A})=n-\operatorname{rank}\mathbf{A}$ by Theorem 2.5.7. Consistency is what makes the set non-empty, and Theorem 2.5.8

says when it holds.

(d) A special case of (a) with $V = \mathbb{F}_2^2$: four points, direction space $\mathbb{F}_2^2$, dimension 2. It is worth seeing because it is so small. Every pair of distinct points $P \neq Q$ has $\overrightarrow{PQ} = \overrightarrow{QP}$, since $-1 = 1$ in $\mathbb{F}_2$; the next section will call a coset of a one-dimensional subspace a **line**, and here each such coset has exactly two points. So every one of the $\binom{4}{2} = 6$ pairs of distinct points is itself a line, and the six lines fall into three pairs with no point in common.

A non-example, by minimal change. Delete one point from the plane: let $\mathcal{A} = \mathbb{R}^2 \setminus \{\mathbf{0}\}$, with $\overrightarrow{\mathbf{xy}} = \mathbf{y} - \mathbf{x}$. Chasles still holds, because it is an identity about subtraction. But (AS2) fails: for $P = (1, 0)$, no point Q of $\mathcal{A}$ has $\overrightarrow{PQ} = (-1, 0)$, since the only candidate is $\mathbf{0}$, which we removed. The map $Q \mapsto \overrightarrow{PQ}$ is injective but not surjective. It is exactly the transitivity of the action that fails: the set has a hole.

Warning. **A point is not a vector.** In an affine space there is no zero point; and over a field in which $2 \neq 0$ and $3 \neq 0$ there is no sum $P + Q$ of two points and no multiple $3P$. The only legal expressions are $\overrightarrow{PQ} \in V$, $P + \mathbf{v} \in \mathcal{A}$, and the affine combinations defined below. If you find yourself writing $P + Q$, you have silently chosen an origin; the next subsection says what that costs.

21.1.2 Choosing an origin

An affine space looks like its direction space as soon as one point is nominated as the zero. This is the chapter's first named move, and it is used in almost every proof that follows: *to compute, pick an origin; to state a result, do not.*

Proposition 21.1.3 — Choice of Origin

Let $\mathcal{A}$ be an affine space with direction space V, and let $O \in \mathcal{A}$. Then

$$\theta_O \colon \mathcal{A} \to V, \qquad \theta_O(P) = \overrightarrow{OP},$$

is a bijection with $\theta_O(O) = \mathbf{0}$, and it carries the affine structure of $\mathcal{A}$ to that of V in Example (Four affine spaces) (a):

$$\overrightarrow{PQ} = \theta_O(Q) - \theta_O(P) \qquad (P, Q \in \mathcal{A}).$$

If $O' \in \mathcal{A}$ is another point, then $\theta_{O'}(P) = \theta_O(P) - \theta_O(O')$ for every P: the two identifications differ by a translation of V.

Proof. θ_O is a bijection by (AS2), and $\theta_O(O) = \overrightarrow{OO} = \mathbf{0}$ by Lemma 21.1.1 (a). By Chasles and the same lemma,

$$\theta_O(Q) - \theta_O(P) = \overrightarrow{OQ} - \overrightarrow{OP} = \overrightarrow{OQ} + \overrightarrow{PO} = \overrightarrow{PQ}.$$

For the last statement, apply this with P and O' in place of Q and P: $\theta_{O'}(P) = \overrightarrow{O'P} = \theta_O(P) - \theta_O(O')$.

■

So an n-dimensional affine space over F is a copy of F^n with the labels rubbed off. Choosing O writes the labels back on, and any two choices differ by a translation. We write $\mathbb{A}^n(F)$ for F^n regarded as an affine space over itself, and $\mathbb{A}^n$ when $F = \mathbb{R}$; its points are written $P = (p_1, \dots, p_n)$, in plain type, even though the same list of numbers written $\mathbf{p}$ would be a vector.

> *Warning.* **The identification is never canonical.** Proposition 21.1.3 does not say that $\mathcal{A}$ "is" V; it says that each point of $\mathcal{A}$ gives one isomorphism, and there are as many as there are points. A statement proved after choosing O is a statement about $\mathcal{A}$ only if it does not depend on which O was chosen. Checking that independence is a real obligation, and the next subsection is nothing but that check, done once for all.

21.1.3 Affine combinations

Sums of points are forbidden, and yet the centroid $\frac{1}{3}(P_1 + P_2 + P_3)$ of a triangle is a genuine point of the plane, independent of any coordinate system. Something with weights adding up to 1 survives the loss of the origin. Here is the computation that says which expressions survive.

Fix $O \in \mathcal{A}$, points $P_1, \dots, P_k \in \mathcal{A}$ and scalars $t_1, \dots, t_k \in F$ with $s := t_1 + \cdots + t_k$. Let $O' \in \mathcal{A}$ and $\mathbf{w} = \overrightarrow{OO'}$. Since $\overrightarrow{O'P_i} = \overrightarrow{O'O} + \overrightarrow{OP_i} = \overrightarrow{OP_i} - \mathbf{w}$,

$$\sum_{i=1}^{k} t_i \overrightarrow{O'P_i} = \sum_{i=1}^{k} t_i \overrightarrow{OP_i} - s\mathbf{w}, \tag{21.1.1}$$

and therefore, adding this vector to the point $O' = O + \mathbf{w}$ and using Lemma 21.1.1 (b), we get the companion identity for points.

$$O' + \sum_{i=1}^{k} t_i \overrightarrow{O'P_i} = \left(O + \sum_{i=1}^{k} t_i \overrightarrow{OP_i}\right) + (1 - s)\mathbf{w}. \tag{21.1.2}$$

The vector on the left of Eq. 21.1.1 does not depend on the origin exactly when $s = 0$; the point on the left of Eq. 21.1.2 does not depend on it exactly when $s = 1$. Both cases are worth a name.

Weights adding to one make a point; weights adding to zero make a vector; nothing else means anything.

Definition 21.1.2 — Affine Combination

Let $\mathcal{A}$ be an affine space with direction space V, let $P_1, \dots, P_k \in \mathcal{A}$ with $k \geq 1$, and let $t_1, \dots, t_k \in F$.

(a) If $t_1 + \cdots + t_k = 1$, the **affine combination** $\sum_i t_i P_i$ is the **point** $O + \sum_i t_i \overrightarrow{OP_i}$, for any $O \in \mathcal{A}$.

(b) If $t_1 + \cdots + t_k = 0$, the expression $\sum_i t_i P_i$ denotes the **vector** $\sum_i t_i \overrightarrow{OP_i} \in V$, for any $O \in \mathcal{A}$.

For no other value of $t_1 + \cdots + t_k$ is $\sum_i t_i P_i$ defined.

In words: the same symbol means a point when the weights add up to 1 and a vector when they add up to 0, and the type of the answer is read off from the weights. The simplest instance of (b) is $k = 2$ with weights $(-1, 1)$: the vector $Q - P$ is $\overrightarrow{PQ}$. The simplest instance of (a) is $k = 1$ with $t_1 = 1$, which is P_1.

Proposition 21.1.4 — Affine combinations are exactly the origin-free ones

With the notation of Definition 21.1.2, put $s = t_1 + \cdots + t_k$.

(a) If $s = 1$, the point $O + \sum_i t_i \overrightarrow{OP_i}$ is the same for every $O \in \mathcal{A}$.

(b) If $s = 0$, the vector $\sum_i t_i \overrightarrow{OP_i}$ is the same for every $O \in \mathcal{A}$.

(c) Suppose $\dim \mathcal{A} \geq 1$. If $s \neq 1$, there are points $P_1, \ldots, P_k$ and origins O, O' for which $O + \sum_i t_i \overrightarrow{OP_i}$ and $O' + \sum_i t_i \overrightarrow{O'P_i}$ differ; and if $s \neq 0$, the same is true of the vectors $\sum_i t_i \overrightarrow{OP_i}$.

Proof.

(a) and (b) are Eq. 21.1.2 and Eq. 21.1.1 with $1 - s = 0$ and $s = 0$ respectively, since O' was an arbitrary point of $\mathcal{A}$.

(b) Since $\dim \mathcal{A} \geq 1$, the direction space V contains some $\mathbf{w} \neq \mathbf{0}$. Take any $O \in \mathcal{A}$, put $O' = O + \mathbf{w}$, and take $P_1 = \cdots = P_k = O$, so that $\overrightarrow{OP_i} = \mathbf{0}$ for every i. Then Eq. 21.1.2 reads

$$O' + \sum_i t_i \overrightarrow{O'P_i} = O + (1 - s)\mathbf{w},$$

which differs from $O + \sum_i t_i \overrightarrow{OP_i} = O$ when $(1 - s)\mathbf{w} \neq \mathbf{0}$, that is, when $s \neq 1$, by Lemma 21.1.1 (c). Likewise Eq. 21.1.1 reads $\sum_i t_i \overrightarrow{O'P_i} = -s\mathbf{w}$, which differs from $\sum_i t_i \overrightarrow{OP_i} = \mathbf{0}$ when $s \neq 0$.

■

Taking $\mathcal{A} = V$ over $\mathbb{R}$ and $O = \mathbf{0}$, part (a) becomes the ordinary vector expression $\sum_i t_i \mathbf{x}_i$ with $\sum_i t_i = 1$, which is Chapter 17's affine combination (Definition 17.1.5 (a)). So Definition 21.1.2 extends that notion from a real vector space to an affine space over any field, and adds the companion vector-valued case. Chapter 17's affine hull $\operatorname{aff} S$ and its description as a coset (Proposition 17.1.4) are the real case of the flats of the next section.

Quick check. Let $f : \mathbb{R} \to \mathbb{R}$ be $f(x) = 2x + 3$, which is not linear. Compute $f(3 \cdot 1 - 2 \cdot 2)$ and $3f(1) - 2f(2)$; then compute $f(1 + 2)$ and $f(1) + f(2)$. What do the two pairs show?

Solution. First pair: $3 \cdot 1 - 2 \cdot 2 = -1$ and $f(-1) = 1$, while $3f(1) - 2f(2) = 3 \cdot 5 - 2 \cdot 7 = 1$. They agree, and the weights 3 and -2 add up to 1. Second pair: $f(3) = 9$, while $f(1) + f(2) = 5 + 7 = 12$. They differ, and the weights 1 and 1 add up to 2. So f respects combinations whose weights add up to 1 and destroys the others: it is affine but not linear. That is the content of the next subsection.

21.1.4 Affine maps

Linear maps are the functions that respect the structure of a vector space. Affine maps should be the functions that respect the structure of an affine space, and by Definition 21.1.2 that structure is: which affine combinations equal which points. So there is only one reasonable definition.

An affine map is one that can be applied inside an affine combination.

Definition 21.1.3 — Affine Map

Let $\mathcal{A}$ and $\mathcal{B}$ be affine spaces over the same field F, with direction spaces V and W. A map $f\colon \mathcal{A} \to \mathcal{B}$ is **affine** if

$$f\Big(\sum_{i=1}^{k} t_i P_i\Big) = \sum_{i=1}^{k} t_i f(P_i)$$

for every $k \geq 1$, all $P_1, \dots, P_k \in \mathcal{A}$ and all $t_1, \dots, t_k \in F$ with $t_1 + \cdots + t_k = 1$.

Both sides are points, by Definition 21.1.2 (a) applied in $\mathcal{A}$ and in $\mathcal{B}$. Nothing is asked about weights summing to anything else, and by the Quick check above nothing could be.

The definition quantifies over all k, which is awkward to verify. The next theorem replaces it by a single linear map, and is the result the rest of the chapter uses.

Theorem 21.1.5 — An Affine Map Is Linear Plus a Translation

Let $\mathcal{A}, \mathcal{B}$ be affine spaces over F with direction spaces V, W, and let $f\colon \mathcal{A} \to \mathcal{B}$. The following are equivalent.

(a) f is affine.

(b) There is a linear map $T\colon V \to W$ with $\overrightarrow{f(P)f(Q)} = T(\overrightarrow{PQ})$ for all $P, Q \in \mathcal{A}$.

(c) For **some** $O \in \mathcal{A}$ there is a linear map $T\colon V \to W$ with $f(P) = f(O) + T(\overrightarrow{OP})$ for all $P \in \mathcal{A}$.

The map T in (b) and (c) is unique, is the same in both, and does not depend on O. It is called the **linear part** of f and written $\vec{f}$.

Idea. The cycle is (a) $\Rightarrow$ (c) $\Rightarrow$ (b) $\Rightarrow$ (a). For (a) $\Rightarrow$ (c) we must manufacture a linear map out of a condition about weights, so we need the two vector-space axioms written as affine combinations. They are

$$O + (\mathbf{u} + \mathbf{w}) = (O + \mathbf{u}) + (O + \mathbf{w}) - O, \qquad O + \lambda\mathbf{u} = \lambda(O + \mathbf{u}) + (1 - \lambda)O,$$

whose weights add up to $1 - 1 + 1 = 1$ and $\lambda + (1 - \lambda) = 1$. Applying f to each is additivity and homogeneity of T.

Proof.

(a) $\Rightarrow$ (c). Fix $O \in \mathcal{A}$ and define $T\colon V \to W$ by $T(\mathbf{v}) = \overrightarrow{f(O)\,f(O + \mathbf{v})}$; this is a map because $O + \mathbf{v}$ is a well-defined point. Then $f(O + \mathbf{v}) = f(O) + T(\mathbf{v})$ by the

definition of $+$ in $\mathcal{B}$, so once T is shown to be linear, taking $\mathbf{v} = \overrightarrow{OP}$ gives (c).

Additivity. Let $\mathbf{u}, \mathbf{w} \in V$. The three points $O+\mathbf{u}$, $O+\mathbf{w}$, O with weights $1, 1, -1$ have weight sum 1, and their affine combination, computed with origin O, is $O+(\mathbf{u}+\mathbf{w}-\mathbf{0}) = O+(\mathbf{u}+\mathbf{w})$. Applying (a) and computing the right-hand side with origin $f(O)$,

$$\begin{aligned} f(O+\mathbf{u}+\mathbf{w}) &= f(O+\mathbf{u}) + f(O+\mathbf{w}) - f(O) \\ &= f(O) + \big(T(\mathbf{u}) + T(\mathbf{w})\big), \end{aligned}$$

so $T(\mathbf{u}+\mathbf{w}) = T(\mathbf{u}) + T(\mathbf{w})$.

Homogeneity. Let $\lambda \in F$. The two points $O+\mathbf{u}$ and O with weights λ and $1-\lambda$ have weight sum 1, and their affine combination with origin O is $O+\lambda\mathbf{u}$. Applying (a) and computing with origin $f(O)$,

$$f(O+\lambda\mathbf{u}) = \lambda f(O+\mathbf{u}) + (1-\lambda) f(O) = f(O) + \lambda T(\mathbf{u}),$$

so $T(\lambda\mathbf{u}) = \lambda T(\mathbf{u})$. Hence T is linear.

(c) $\Rightarrow$ (b). Let O and T be as in (c) and let $P, Q \in \mathcal{A}$. Then $f(P) = f(O) + T(\overrightarrow{OP})$ and $f(Q) = f(O) + T(\overrightarrow{OQ})$, so by Proposition 21.1.3 applied in $\mathcal{B}$ with origin $f(O)$, and then linearity of T,

$$\overrightarrow{f(P)f(Q)} = T(\overrightarrow{OQ}) - T(\overrightarrow{OP}) = T(\overrightarrow{OQ} - \overrightarrow{OP}) = T(\overrightarrow{PQ}),$$

the last equality by Proposition 21.1.3 in $\mathcal{A}$.

(d) $\Rightarrow$ (a). Let T be as in (b), let $\sum_i t_i = 1$, and put $X = \sum_i t_i P_i$. Choose any $O \in \mathcal{A}$, so that $\overrightarrow{OX} = \sum_i t_i \overrightarrow{OP_i}$ by Definition 21.1.2. Applying (b) to the pairs (O, X) and (O, P_i), and then linearity,

$$\overrightarrow{f(O)f(X)} = T(\overrightarrow{OX}) = \sum_i t_i\, T(\overrightarrow{OP_i}) = \sum_i t_i \overrightarrow{f(O)f(P_i)}.$$

The right-hand side is, by Definition 21.1.2 computed in $\mathcal{B}$ with origin $f(O)$, the displacement from $f(O)$ to $\sum_i t_i f(P_i)$. Hence $f(X) = \sum_i t_i f(P_i)$, which is (a).

Uniqueness. Suppose T and T' both satisfy (b). Given $\mathbf{v} \in V$, fix O and put $Q = O+\mathbf{v}$; then $T(\mathbf{v}) = \overrightarrow{f(O)f(Q)} = T'(\mathbf{v})$. So T is determined by f, independently of any origin; and a T satisfying (c) for one O satisfies (b) by the implication above, hence is this same map. This proves the theorem.

■

So an affine map is *one linear map plus one displacement*, no more. In $\mathbb{A}^n(F) \to \mathbb{A}^m(F)$ it is

$$f(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b}, \qquad \mathbf{A} \in M_{m\times n}(F),\ \mathbf{b} \in F^m,$$

with $\mathbf{A}$ the matrix of $\vec{f}$ in the standard bases and $\mathbf{b} = f(\mathbf{0})$.

Warning. **Affine is weaker than linear, and the difference is exactly the origin.** An affine map $f\colon V \to W$ between *vector spaces* is linear if and only if $f(\mathbf{0}) = \mathbf{0}$: if $f(\mathbf{x}) = T(\mathbf{x}) + \mathbf{b}$ then $f(\mathbf{0}) = \mathbf{b}$, and f is linear exactly when $\mathbf{b} = \mathbf{0}$. The translation $\tau(\mathbf{x}) = \mathbf{x} + \mathbf{b}$ with $\mathbf{b} \neq \mathbf{0}$ is affine with linear part id_V and is **not** linear — Chapter 3 recorded it as Example (Translation), the standard non-example of a linear map.

Conversely $x \mapsto x^2$ on $\mathbb{R}$ fixes 0 and is not affine: it sends the affine combination $2 \cdot 1 + (-1) \cdot 0 = 1$ to 1, while $2f(1) - f(0) = 2$.

An affine map is determined by very little, but not by too little. Here is the negative half; the positive half is the subject of the next section.

Example. (Two points are not enough in the plane)

Let $f, g \colon \mathbb{A}^2 \to \mathbb{A}^2$ be $g(x, y) = (x, y)$ and $f(x, y) = (x + y,\ y)$. Both are affine, being linear. They agree at the two distinct points $(0, 0)$ and $(1, 0)$ — indeed at every point of the line $y = 0$ — yet $f(0, 1) = (1, 1) \neq (0, 1) = g(0, 1)$. So two points, even distinct ones, do not determine an affine map of the plane. The count to remember is $n + 1$: the next section proves that 3 suitably chosen points do determine an affine map of the plane, and that 2 never will.

21.1.5 The affine group, and the matrix that computes it

Affine maps compose, and the linear part is functorial. That single fact organizes every computation in the chapter.

Theorem 21.1.6 — Composition, Inverses, and the Affine Group

Let $\mathcal{A}, \mathcal{B}, \mathcal{C}$ be affine spaces over F, and write V and W for the direction spaces of $\mathcal{A}$ and $\mathcal{B}$.

(a) If $f \colon \mathcal{A} \to \mathcal{B}$ and $g \colon \mathcal{B} \to \mathcal{C}$ are affine, then $g \circ f$ is affine and $\overrightarrow{g \circ f} = \vec{g} \circ \vec{f}$.

(b) An affine $f \colon \mathcal{A} \to \mathcal{B}$ is bijective if and only if $\vec{f}$ is bijective, and then f^{-1} is affine with $\overrightarrow{f^{-1}} = (\vec{f})^{-1}$.

(c) The bijective affine maps $\mathcal{A} \to \mathcal{A}$ form a group $\mathrm{Aff}(\mathcal{A})$ under composition, and $f \mapsto \vec{f}$ is a surjective group homomorphism $\mathrm{Aff}(\mathcal{A}) \to \mathrm{GL}(V)$ whose kernel is the set of **translations** $\tau_{\mathbf{v}} \colon P \mapsto P + \mathbf{v}$, $\mathbf{v} \in V$.

Idea. Everything is read off from the identity $\overrightarrow{f(P)f(Q)} = \vec{f}(\overrightarrow{PQ})$ of Theorem 21.1.5 (b), which turns statements about points into statements about vectors. For (c), the kernel consists of the affine maps whose linear part is the identity, and such a map moves every point by the same vector.

Proof.

(a) For $P, Q \in \mathcal{A}$, applying Theorem 21.1.5 (b) twice,

$$\overrightarrow{g(f(P))\,g(f(Q))} = \vec{g}\big(\overrightarrow{f(P)f(Q)}\big) = \vec{g}\big(\vec{f}(\overrightarrow{PQ})\big).$$

Since $\vec{g} \circ \vec{f}$ is linear (Theorem 3.4.2), condition (b) of that theorem holds for $g \circ f$ with this map, so $g \circ f$ is affine and, by the uniqueness clause, $\overrightarrow{g \circ f} = \vec{g} \circ \vec{f}$.

(b) ($\Leftarrow$) Suppose $\vec{f}$ is bijective. If $f(P) = f(Q)$ then $\vec{f}(\overrightarrow{PQ}) = \overrightarrow{f(P)f(Q)} = \mathbf{0}$, so $\overrightarrow{PQ} = \mathbf{0}$ and $P = Q$ by Lemma 21.1.1 (c); thus f is injective. For surjectivity, fix $O \in \mathcal{A}$ and let $R \in \mathcal{B}$. As $\vec{f}$ is onto, $\overrightarrow{f(O)R} = \vec{f}(\mathbf{v})$ for some $\mathbf{v} \in V$, and then $f(O + \mathbf{v}) = f(O) + \vec{f}(\mathbf{v}) = R$ by part (c) of Theorem 21.1.5.
($\Rightarrow$) Suppose f is bijective and fix $O \in \mathcal{A}$. If $\vec{f}(\mathbf{v}) = \mathbf{0}$, then $f(O+\mathbf{v}) = f(O)+\mathbf{0} = f(O)$, so $O + \mathbf{v} = O$ and $\mathbf{v} = \mathbf{0}$; thus $\vec{f}$ is injective. Given $\mathbf{w} \in W$, the point $f(O) + \mathbf{w}$ is $f(P)$ for some P, and then $\mathbf{w} = \overrightarrow{f(O)f(P)} = \vec{f}(\overrightarrow{OP})$; thus $\vec{f}$ is onto. For the inverse, let $R, S \in \mathcal{B}$ and put $P = f^{-1}(R)$, $Q = f^{-1}(S)$. Then $\vec{f}(\overrightarrow{PQ}) = \overrightarrow{RS}$, so $\overrightarrow{f^{-1}(R)f^{-1}(S)} = (\vec{f})^{-1}(\overrightarrow{RS})$. Since $(\vec{f})^{-1}$ is linear (Theorem 3.5.1), f^{-1} is affine with the stated linear part.

(c) By (a) and (b), $\mathrm{Aff}(\mathcal{A})$ is closed under composition and inverses and contains $\mathrm{id}_{\mathcal{A}}$, whose linear part is id_V; composition of functions is associative, so it is a group (Definition 0.10.1). By (a) the map $f \mapsto \vec{f}$ preserves composition, and by (b) it lands in $\mathrm{GL}(V)$; so it is a homomorphism (Definition 0.10.3). It is onto: given $T \in \mathrm{GL}(V)$, fix O and set $f(P) = O + T(\overrightarrow{OP})$, which is affine with $\vec{f} = T$ by Theorem 21.1.5 (c) and bijective by (b).

Its kernel is $\{f : \vec{f} = \mathrm{id}_V\}$. Each translation $\tau_{\mathbf{v}}$ lies there, since $\overrightarrow{\tau_{\mathbf{v}}(P)\tau_{\mathbf{v}}(Q)} = \overrightarrow{PQ}$ by Chasles. Conversely suppose $\vec{f} = \mathrm{id}_V$, fix O and put $\mathbf{v} = \overrightarrow{Of(O)}$. For any P, Chasles gives

$$\overrightarrow{Pf(P)} = \overrightarrow{PO} + \overrightarrow{Of(O)} + \overrightarrow{f(O)f(P)} = \overrightarrow{PO} + \mathbf{v} + \overrightarrow{OP} = \mathbf{v},$$

so $f(P) = P + \mathbf{v} = \tau_{\mathbf{v}}(P)$. This proves the theorem.

■

In coordinates the homomorphism of (c) is visible in the shape of a matrix. Identify $\mathbf{x} \in F^n$ with the column $\binom{\mathbf{x}}{1} \in F^{n+1}$ — the points of $\mathbb{A}^n(F)$ become the vectors of F^{n+1} whose last coordinate is 1.

Proposition 21.1.7 — The Block Matrix of an Affine Map

Let $f\colon \mathbb{A}^n(F) \to \mathbb{A}^m(F)$ be affine, $f(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b}$ with $\mathbf{A} \in M_{m\times n}(F)$ the matrix of $\vec{f}$ and $\mathbf{b} = f(\mathbf{0})$. Put

$$\widehat{f} = \begin{pmatrix} \mathbf{A} & \mathbf{b} \\ \mathbf{0}^{\top} & 1 \end{pmatrix} \in M_{(m+1)\times(n+1)}(F).$$

Then $\widehat{f}\binom{\mathbf{x}}{1} = \binom{f(\mathbf{x})}{1}$ for every $\mathbf{x} \in F^n$; and for affine $f\colon \mathbb{A}^n(F) \to \mathbb{A}^m(F)$ and $g\colon \mathbb{A}^m(F) \to \mathbb{A}^p(F)$ one has $\widehat{g \circ f} = \widehat{g}\,\widehat{f}$. For $m = n$, f is bijective if and only if $\mathbf{A}$ is invertible, and then

$$\widehat{f^{-1}} = (\widehat{f})^{-1} = \begin{pmatrix} \mathbf{A}^{-1} & -\mathbf{A}^{-1}\mathbf{b} \\ \mathbf{0}^{\top} & 1 \end{pmatrix}.$$

Proof. Block multiplication (Theorem 7.1.1) gives

$$\begin{pmatrix} \mathbf{A} & \mathbf{b} \\ \mathbf{0}^{\top} & 1 \end{pmatrix} \begin{pmatrix} \mathbf{x} \\ 1 \end{pmatrix} = \begin{pmatrix} \mathbf{A}\mathbf{x} + \mathbf{b} \\ 1 \end{pmatrix},$$

which is the first claim. Writing $g(\mathbf{y}) = \mathbf{C}\mathbf{y} + \mathbf{d}$, the same rule gives

$$\begin{pmatrix} \mathbf{C} & \mathbf{d} \\ \mathbf{0}^{\top} & 1 \end{pmatrix} \begin{pmatrix} \mathbf{A} & \mathbf{b} \\ \mathbf{0}^{\top} & 1 \end{pmatrix} = \begin{pmatrix} \mathbf{C}\mathbf{A} & \mathbf{C}\mathbf{b} + \mathbf{d} \\ \mathbf{0}^{\top} & 1 \end{pmatrix},$$

and $(g \circ f)(\mathbf{x}) = \mathbf{C}(\mathbf{A}\mathbf{x} + \mathbf{b}) + \mathbf{d} = (\mathbf{C}\mathbf{A})\mathbf{x} + (\mathbf{C}\mathbf{b} + \mathbf{d})$, so the two agree. For $m = n$: f is bijective exactly when $\vec{f}$ is, by Theorem 21.1.6 (b), and $\vec{f}$ is bijective exactly when its matrix $\mathbf{A}$ is invertible, by Theorem 3.6.5 (b). In that case $\mathbf{x} \mapsto \mathbf{A}^{-1}\mathbf{x} - \mathbf{A}^{-1}\mathbf{b}$ is affine and is a two-sided inverse of f, and its block matrix is the one displayed, which is therefore $(\widehat{f})^{-1}$ by the composition rule.

■

So composing affine maps is multiplying $(n+1) \times (n+1)$ matrices, and $\mathrm{Aff}(\mathbb{A}^n(F))$ is a group of such matrices. The last row $(\mathbf{0}^{\top} \mid 1)$ is what records "these are points, not vectors"; the projective sections later in this chapter read that row again, as the equation of the hyperplane at infinity, after the extra coordinate is moved from last place to first.

Example. (Composing a shear and a quarter turn)

In $\mathbb{A}^2$ let $f(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b}$ and $g(\mathbf{y}) = \mathbf{C}\mathbf{y} + \mathbf{d}$, where

$$\mathbf{A} = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}, \quad \mathbf{b} = \begin{pmatrix} 1 \\ -1 \end{pmatrix}, \quad \mathbf{C} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad \mathbf{d} = \begin{pmatrix} 2 \\ 0 \end{pmatrix}.$$

Compute $g \circ f$ in block form, and find f^{-1}.

Solution. The block matrices multiply as

$$\begin{pmatrix} 0 & -1 & 2 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 2 & 1 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & -1 & 3 \\ 1 & 2 & 1 \\ 0 & 0 & 1 \end{pmatrix},$$

so $(g \circ f)(x, y) = (-y + 3,\ x + 2y + 1)$. **Check directly:** $f(x, y) = (x + 2y + 1,\ y - 1)$, and applying g gives $(-(y-1) + 2,\ x + 2y + 1) = (3 - y,\ x + 2y + 1)$, the same.

For the inverse, $\mathbf{A}^{-1} = \begin{pmatrix} 1 & -2 \\ 0 & 1 \end{pmatrix}$ and $-\mathbf{A}^{-1}\mathbf{b} = -\begin{pmatrix} 1 & -2 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 \\ -1 \end{pmatrix} = \begin{pmatrix} -3 \\ 1 \end{pmatrix}$, so $f^{-1}(x, y) = (x - 2y - 3,\ y + 1)$. **Check:** $f^{-1}(f(x, y)) = \big((x + 2y + 1) - 2(y - 1) - 3,\ (y - 1) + 1\big) = (x, y)$.

Two things have been set up. Affine maps are linear maps that have forgotten where the origin is, and they are computed by one matrix of size one larger. The next section uses both to describe the subsets of an affine space that are themselves affine spaces.

21.1.6 Exercises

21.1.6.1 A. Check your understanding

Exercise A1.

(a) State Chasles's relation, and deduce $\overrightarrow{QP} = -\overrightarrow{PQ}$ from it.

(b) In an affine space over a field in which $2 \neq 0$ and $3 \neq 0$, which of $P + Q$, $3P$, $\overrightarrow{PQ} + \overrightarrow{RS}$, $P + \overrightarrow{QR}$, $\frac{1}{2}P + \frac{1}{2}Q$ are defined? For each defined one, say whether it is a point or a vector.

(c) True or false, with a reason: a map $f\colon \mathbb{R}^2 \to \mathbb{R}^2$ with $f(\mathbf{0}) = \mathbf{0}$ is affine if and only if it is linear.

(d) An affine map $f\colon \mathbb{A}^3 \to \mathbb{A}^3$ has $\vec{f}$ of rank 2. Is f injective? Justify your answer.

Solution.

(a) $\overrightarrow{PQ} + \overrightarrow{QR} = \overrightarrow{PR}$ for all points P, Q, R. Taking $R = P$ gives $\overrightarrow{PQ} + \overrightarrow{QP} = \overrightarrow{PP}$, and $\overrightarrow{PP} = \mathbf{0}$ by Lemma 21.1.1 (a); hence $\overrightarrow{QP} = -\overrightarrow{PQ}$.

(b) $P + Q$ and $3P$ are **not** defined: the weights add up to 2 and to 3, and under the hypotheses on F neither sum is 0 or 1, so Definition 21.1.2 gives these expressions no meaning; Proposition 21.1.4 (c) says why nothing could, since for $\dim \mathcal{A} \geq 1$ no such expression is origin-free. $\overrightarrow{PQ} + \overrightarrow{RS}$ is a vector (a sum in V). $P + \overrightarrow{QR}$ is a point. $\frac{1}{2}P + \frac{1}{2}Q$ is a point, the midpoint, and $\frac{1}{2}$ exists because $2 \neq 0$. (The hypotheses on F are needed: over $\mathbb{F}_2$ the weights of $P + Q$ add up to $2 = 0$, and Definition 21.1.2 (b) makes $P + Q$ the vector $\overrightarrow{OP} + \overrightarrow{OQ} = \overrightarrow{PQ}$.)

(c) True. An affine map is $f(\mathbf{x}) = T(\mathbf{x}) + \mathbf{b}$ with T linear and $\mathbf{b} = f(\mathbf{0})$ (Theorem 21.1.5), so $f(\mathbf{0}) = \mathbf{0}$ forces $\mathbf{b} = \mathbf{0}$ and $f = T$. Conversely every linear map is affine, with $\vec{f} = f$, and sends $\mathbf{0}$ to $\mathbf{0}$.

(d) No. By Theorem 21.1.6 (b), f is bijective exactly when $\vec{f}$ is, and for an operator on a finite-dimensional space injective, surjective and bijective agree (Theorem 3.5.7). Here $\operatorname{rank} \vec{f} = 2 < 3$, so $\vec{f}$ is not injective; taking $\mathbf{v} \neq \mathbf{0}$ in $\ker \vec{f}$ and any P, the points P and $P + \mathbf{v}$ have the same image, since $\overrightarrow{f(P)f(P+\mathbf{v})} = \vec{f}(\mathbf{v}) = \mathbf{0}$.

21.1.6.2 B. Practice

Exercise B1: Determine which are affine.

Determine which of the following maps are affine. Justify your answer; for each affine one give its linear part, and for each other one name a failing affine combination.

(a) $f\colon \mathbb{A}^2 \to \mathbb{A}^2$, $f(x, y) = (2x - y + 1,\ 5)$.

(b) $f\colon \mathbb{A}^2 \to \mathbb{A}^1$, $f(x, y) = xy$.

(c) $f\colon \mathbb{A}^1 \to \mathbb{A}^2$, $f(t) = (1 - t,\ 2 + 3t)$.

(d) $f\colon \mathbb{A}^2 \to \mathbb{A}^2$, $f(x, y) = (x + 1,\ |y|)$.

Solution.

(a) Affine: $f(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b}$ with $\mathbf{A} = \begin{pmatrix} 2 & -1 \\ 0 & 0 \end{pmatrix}$ and $\mathbf{b} = (1, 5)$. Its linear part is $\mathbf{x} \mapsto \mathbf{A}\mathbf{x}$, of rank 1.

(b) Not affine. Take the affine combination $2(1, 1) - 1 \cdot (0, 0) = (2, 2)$, with weights $2 + (-1) = 1$. Then $f(2, 2) = 4$, while $2f(1, 1) - f(0, 0) = 2$.

(c) Affine: $f(t) = \mathbf{A}t + \mathbf{b}$ with $\mathbf{A} = \begin{pmatrix} -1 \\ 3 \end{pmatrix}$ and $\mathbf{b} = (1, 2)$. Linear part $t \mapsto (-t, 3t)$, of rank 1.

(d) Not affine. Take the affine combination $2(0,1) - 1 \cdot (0,3) = (0,-1)$, with weights $2 + (-1) = 1$. Then $f(0,-1) = (1,1)$, while $2f(0,1) - f(0,3) = 2(1,1) - (1,3) = (1,-1)$. The two differ, so f is not affine. (The first coordinate is affine in x; it is $|y|$ that fails.)

Exercise B2: Block matrices.

In $\mathbb{A}^2$, let r be the affine map with $\widehat{r} = \begin{pmatrix} 0 & -1 & 1 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$ and let τ be the translation by $(2, 3)$.

(a) Write r and τ in the form $\mathbf{x} \mapsto \mathbf{A}\mathbf{x} + \mathbf{b}$.

(b) Compute $\widehat{\tau \circ r}$ and $\widehat{r \circ \tau}$, and say whether the two maps are equal.

(c) Find all fixed points of r.

Solution.

(a) $r(x, y) = (-y + 1,\ x)$, that is, $\mathbf{A}_r = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, $\mathbf{b}_r = (1, 0)$. And $\tau(x, y) = (x + 2,\ y + 3)$, with $\mathbf{A}_\tau = \mathbf{I}_2$, $\mathbf{b}_\tau = (2, 3)$.

(b) By Proposition 21.1.7, $\widehat{\tau \circ r} = \widehat{\tau}\,\widehat{r}$ and $\widehat{r \circ \tau} = \widehat{r}\,\widehat{\tau}$:

$$\widehat{\tau}\,\widehat{r} = \begin{pmatrix} 0 & -1 & 3 \\ 1 & 0 & 3 \\ 0 & 0 & 1 \end{pmatrix}, \qquad \widehat{r}\,\widehat{\tau} = \begin{pmatrix} 0 & -1 & -2 \\ 1 & 0 & 2 \\ 0 & 0 & 1 \end{pmatrix}.$$

They differ, so $\tau \circ r \neq r \circ \tau$. (The linear parts agree; the translation vectors do not, because $\vec{r}$ moves $\mathbf{b}_\tau$.)

(c) $r(x, y) = (x, y)$ reads $-y + 1 = x$ and $x = y$, so $x = y = \frac{1}{2}$. The unique fixed point is $(\frac{1}{2}, \frac{1}{2})$. Equivalently, $(\mathbf{I} - \mathbf{A}_r)\mathbf{x} = \mathbf{b}_r$ with $\mathbf{I} - \mathbf{A}_r = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$ invertible.

Exercise B3: The four-point plane.

Let $\mathcal{A} = \mathbb{F}_2^2$ as in Example (Four affine spaces) (d), with points $O = (0,0)$, $P = (1,0)$, $Q = (0,1)$, $R = (1,1)$.

(a) Compute $\overrightarrow{PQ}$ and $\overrightarrow{QP}$, and explain why they are equal.

(b) How many affine combinations of the three points O, P, Q are there, and which points do they give? (A combination is counted by its list of weights.)

(c) How many bijective affine maps $\mathcal{A} \to \mathcal{A}$ are there?

Solution.

(a) $\overrightarrow{PQ} = Q - P = (0,1) - (1,0) = (1,1)$ and $\overrightarrow{QP} = P - Q = (1,1)$. They are equal

because $\overrightarrow{QP} = -\overrightarrow{PQ}$ (Lemma 21.1.1 (a)) and $-\mathbf{v} = \mathbf{v}$ for every $\mathbf{v}$ over $\mathbb{F}_2$.

(b) A weight list $(t_0, t_1, t_2) \in \mathbb{F}_2^3$ with $t_0 + t_1 + t_2 = 1$ has an odd number of ones, so it is one of $(1,0,0), (0,1,0), (0,0,1), (1,1,1)$: four lists. The first three give O, P, Q, and $(1,1,1)$ gives $O + P + Q = (1,1) = R$. So the four affine combinations give the four points, each exactly once.

(c) By Theorem 21.1.6 (c) an affine bijection is a translation composed with a linear one, and the number of pairs $(T, \mathbf{v}) \in \mathrm{GL}(\mathbb{F}_2^2) \times \mathbb{F}_2^2$ is $|\mathrm{GL}_2(\mathbb{F}_2)| \cdot 4$. A matrix in $\mathrm{GL}_2(\mathbb{F}_2)$ has a non-zero first column (3 choices) and a second column outside the span of the first ($4 - 2 = 2$ choices), so $|\mathrm{GL}_2(\mathbb{F}_2)| = 6$ and there are 24 affine bijections. Since $|\mathcal{A}| = 4$, these are **all** $4! = 24$ permutations of the four points.

21.1.6.3 C. Going deeper

Exercise C1: Fixed points.

Let $f\colon \mathbb{A}^n \to \mathbb{A}^n$ be affine, $f(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b}$.

(a) Prove that f has a fixed point if and only if $\mathbf{b} \in \mathrm{col}(\mathbf{I} - \mathbf{A})$, and that the set of fixed points, when non-empty, is a coset of $\mathrm{nul}(\mathbf{I} - \mathbf{A})$.

(b) Deduce that if 1 is not an eigenvalue of $\mathbf{A}$, then f has exactly one fixed point.

(c) Give an affine map of $\mathbb{A}^2$ with no fixed point and linear part $\neq \mathrm{id}$.

Solution.

(a) $f(\mathbf{x}) = \mathbf{x}$ says $\mathbf{A}\mathbf{x} + \mathbf{b} = \mathbf{x}$, that is, $(\mathbf{I} - \mathbf{A})\mathbf{x} = \mathbf{b}$. This system is consistent exactly when $\mathbf{b} \in \mathrm{col}(\mathbf{I} - \mathbf{A})$ (Theorem 2.1.1), and then its solution set is $\mathbf{p} + \mathrm{nul}(\mathbf{I} - \mathbf{A})$ for any one solution $\mathbf{p}$, by Theorem 2.1.3.

(b) If 1 is not an eigenvalue of $\mathbf{A}$, then $\mathrm{nul}(\mathbf{I} - \mathbf{A}) = \{\mathbf{0}\}$, so $\mathbf{I} - \mathbf{A}$ is invertible (Theorem 2.4.4). Hence $(\mathbf{I} - \mathbf{A})\mathbf{x} = \mathbf{b}$ has the unique solution $\mathbf{x} = (\mathbf{I} - \mathbf{A})^{-1}\mathbf{b}$.

(c) Take $\mathbf{A} = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}$ and $\mathbf{b} = (1, 0)$, so $f(x, y) = (x+1,\ 2y)$. Then $\mathbf{I} - \mathbf{A} = \begin{pmatrix} 0 & 0 \\ 0 & -1 \end{pmatrix}$ and $\mathrm{col}(\mathbf{I} - \mathbf{A}) = \mathrm{span}(\mathbf{e}_2)$, which does not contain $\mathbf{b} = \mathbf{e}_1$; so there is no fixed point, by (a). And $\mathbf{A} \neq \mathbf{I}$.

Exercise C2: Affine maps on two points, over two fields.

Let $f\colon \mathcal{A} \to \mathcal{B}$ be a map of affine spaces over F that preserves affine combinations of **two** points, that is, $f((1-t)P + tQ) = (1-t)f(P) + tf(Q)$ for all $P, Q \in \mathcal{A}$ and $t \in F$.

(a) Prove that if $\mathrm{char}\, F \neq 2$, then f is affine. *Hint: run the proof of Theorem 21.1.5, replacing the three-point combination by two two-point ones.*

(b) Show that over $\mathbb{F}_2$ the hypothesis is empty, and give a non-affine map $\mathbb{F}_2^2 \to \mathbb{F}_2$ satisfying it.

Solution.

(a) Fix $O \in \mathcal{A}$ and define $T(\mathbf{v}) = \overrightarrow{f(O)f(O+\mathbf{v})}$ as in Theorem 21.1.5. Homogeneity is the hypothesis with $P = O + \mathbf{v}$, $Q = O$: $O + \lambda\mathbf{v} = \lambda(O + \mathbf{v}) + (1 - \lambda)O$, so $f(O + \lambda\mathbf{v}) = \lambda f(O + \mathbf{v}) + (1 - \lambda)f(O) = f(O) + \lambda T(\mathbf{v})$, giving $T(\lambda\mathbf{v}) = \lambda T(\mathbf{v})$.

For additivity, let $\mathbf{u}, \mathbf{w} \in V$ and let $M = \frac{1}{2}(O+\mathbf{u}) + \frac{1}{2}(O+\mathbf{w})$, which is legal since $2 \neq 0$ in F. With origin O, $M = O + \frac{1}{2}(\mathbf{u}+\mathbf{w})$. By the hypothesis, $f(M) = \frac{1}{2}f(O+\mathbf{u}) + \frac{1}{2}f(O+\mathbf{w})$, which with origin $f(O)$ reads $f(M) = f(O) + \frac{1}{2}(T(\mathbf{u})+T(\mathbf{w}))$. So $T\big(\frac{1}{2}(\mathbf{u}+\mathbf{w})\big) = \frac{1}{2}\big(T(\mathbf{u})+T(\mathbf{w})\big)$. Applying homogeneity with $\lambda = 2$ to the left-hand side gives $T(\mathbf{u}+\mathbf{w}) = T(\mathbf{u})+T(\mathbf{w})$. Hence T is linear, and $f(P) = f(O) + T(\overrightarrow{OP})$ by construction, so f is affine by Theorem 21.1.5 (c).

(b) Over $\mathbb{F}_2$ the only scalars are $t = 0$ and $t = 1$, for which $(1-t)P + tQ$ is P or Q; the required identity then reads $f(P) = f(P)$ or $f(Q) = f(Q)$. So every map satisfies the hypothesis. Take $f\colon \mathbb{F}_2^2 \to \mathbb{F}_2$ with $f(0,0) = f(1,0) = f(0,1) = 0$ and $f(1,1) = 1$. It is not affine: by Exercise (B3: The four-point plane) (b), $(1,1)$ is the affine combination $O + P + Q$ of the other three points with weights $(1,1,1)$, so an affine f would have $f(1,1) = f(O) + f(P) + f(Q) = 0$.

Exercise C3: Conjugating a translation.

Let $\mathcal{A}$ be an affine space with direction space V, let $f \in \mathrm{Aff}(\mathcal{A})$ and let $\mathbf{v} \in V$.

(a) Prove that $f \circ \tau_{\mathbf{v}} \circ f^{-1} = \tau_{\vec{f}(\mathbf{v})}$.

(b) Hence prove that the translations form a subgroup of $\mathrm{Aff}(\mathcal{A})$ that is carried to itself by every conjugation, and that $\mathbf{v} \mapsto \tau_{\mathbf{v}}$ is an isomorphism from $(V,+)$ onto it.

(c) Deduce that if $\dim \mathcal{A} \geq 2$, then $\mathrm{Aff}(\mathcal{A})$ is not abelian.

Solution.

(a) Both sides are affine maps $\mathcal{A} \to \mathcal{A}$. By Theorem 21.1.6 (a) the linear part of the left-hand side is $\vec{f} \circ \mathrm{id}_V \circ (\vec{f})^{-1} = \mathrm{id}_V$, so by the kernel description in Theorem 21.1.6 (c) it is a translation $\tau_{\mathbf{u}}$ for some $\mathbf{u}$. To identify $\mathbf{u}$, fix $O \in \mathcal{A}$ and put $P = f^{-1}(O)$. Then

$$\mathbf{u} = \overrightarrow{O\,(f \circ \tau_{\mathbf{v}} \circ f^{-1})(O)} = \overrightarrow{f(P)\,f(P+\mathbf{v})} = \vec{f}(\mathbf{v}),$$

using Theorem 21.1.5 (b) and $\overrightarrow{P(P+\mathbf{v})} = \mathbf{v}$.

(b) The translations are the kernel of $f \mapsto \vec{f}$ (Theorem 21.1.6 (c)), hence a subgroup by Theorem 0.10.3, and (a) says every conjugate of a translation is a translation. The map $\mathbf{v} \mapsto \tau_{\mathbf{v}}$ satisfies $\tau_{\mathbf{u}} \circ \tau_{\mathbf{w}} = \tau_{\mathbf{u}+\mathbf{w}}$ by Lemma 21.1.1 (b), so it is a homomorphism $(V,+) \to \mathrm{Aff}(\mathcal{A})$; it is onto the translations by definition, and injective because $\tau_{\mathbf{v}} = \mathrm{id}$ forces $P + \mathbf{v} = P$, hence $\mathbf{v} = \mathbf{0}$.

(c) Since $\dim V \geq 2$, pick independent $\mathbf{v}, \mathbf{w} \in V$ and $T \in \mathrm{GL}(V)$ with $T(\mathbf{v}) = \mathbf{w}$ (extend $\{\mathbf{v}, \mathbf{w}\}$ to a basis of V by Theorem 1.8.2, and map that basis to itself with $\mathbf{v}$ and $\mathbf{w}$ swapped, using Theorem 3.1.6; this T is invertible because $T \circ T$ fixes every basis vector and so is id_V, by the uniqueness in that theorem). By Theorem 21.1.6 (c) there is $f \in \mathrm{Aff}(\mathcal{A})$ with $\vec{f} = T$. If $\mathrm{Aff}(\mathcal{A})$ were abelian then $f \circ \tau_{\mathbf{v}} \circ f^{-1} = \tau_{\mathbf{v}}$, while (a) gives $\tau_{T(\mathbf{v})} = \tau_{\mathbf{w}}$; by the injectivity in (b) that forces $\mathbf{v} = \mathbf{w}$, contradicting independence.

21.2 Flats, Independence and Coordinates

An affine space has no origin, so it has no subspaces in the sense of Chapter 1: a subspace must contain $\mathbf{0}$, and there is no $\mathbf{0}$. What it has instead are its **flats** — the lines, planes and hyperplanes that sit inside it. This section defines them, settles when two of them meet and how big the smallest flat containing both is, puts coordinates on an affine space using $n+1$ points rather than n vectors, and shows that in $\mathbb{A}^n(F)$ the flats are exactly the solution sets of linear systems. The join formula has two cases, and the second one is where affine geometry parts company with linear algebra.

Throughout, $\mathcal{A}$ is an affine space over a field F with direction space V (Definition 21.1.1), and from the dimension formula onward $\dim \mathcal{A} = \dim V = n$ is finite, except where a statement says otherwise.

21.2.1 Flats

A subset of $\mathcal{A}$ deserves to be called flat when it is an affine space in its own right, using the same difference map. By Definition 21.1.2 there is only one thing to require.

A flat is a non-empty set of points closed under taking affine combinations.

Definition 21.2.1 — Flat

A subset $A \subseteq \mathcal{A}$ is a **flat**, or an **affine subspace** of $\mathcal{A}$, if it is **non-empty** and contains every affine combination of its own points: **whenever** $k \geq 1$, $P_1, \dots, P_k \in A$ and $t_1, \dots, t_k \in F$ satisfy $t_1 + \cdots + t_k = 1$, the point $\sum_{i=1}^{k} t_i P_i$ lies in A.

The requirement that A be non-empty is a convention, and it is the useful one: a flat is going to have a direction space and a dimension, and the empty set has neither. Intersections of flats may of course be empty, and we will say so each time.

Proposition 21.2.1 — Flats Are the Cosets

Let $A \subseteq \mathcal{A}$ be non-empty. Then A is a flat if and only if there are $P \in \mathcal{A}$ and a subspace U of V with $A = P + U := \{P + \mathbf{u} : \mathbf{u} \in U\}$. In that case:

(a) $U = \{\overrightarrow{XY} : X, Y \in A\}$ is determined by A alone; it is written $\vec{A}$ and called the **direction space** of A.

(b) $A = Q + \vec{A}$ for **every** $Q \in A$, and A, with the difference map of $\mathcal{A}$ restricted to it, is an affine space with direction space $\vec{A}$.

The **dimension** of A is $\dim A := \dim \vec{A}$. A flat of dimension 0 is a single **point**, one of dimension 1 is a **line**, one of dimension 2 is a **plane**, and, when $\dim \mathcal{A} = n$ is finite, one of dimension $n-1$ is a **hyperplane** of $\mathcal{A}$.

Idea. One direction is a computation with origin P. For the other, fix $P \in A$ and let

U be the set of displacements from P to points of A; the three subspace axioms come from three affine combinations, with weight lists (1), $(\lambda, 1-\lambda)$ and $(1, 1, -1)$.

Proof. ($\Leftarrow$) Let $A = P + U$ with U a subspace, and let $P + \mathbf{u}_1, \dots, P + \mathbf{u}_k \in A$ with $\sum_i t_i = 1$. Computing the affine combination with origin P (Definition 21.1.2),

$$\sum_i t_i (P + \mathbf{u}_i) = P + \sum_i t_i \mathbf{u}_i \in P + U,$$

since U is closed under linear combinations. And $A \ni P$ is non-empty.

($\Rightarrow$) Let A be a flat, fix $P \in A$ and put $U = \{\overrightarrow{PX} : X \in A\}$. Then $\mathbf{0} = \overrightarrow{PP} \in U$. If $\mathbf{u} = \overrightarrow{PX} \in U$ and $\lambda \in F$, the point $\lambda X + (1-\lambda)P$ lies in A and equals $P + \lambda\mathbf{u}$ when computed with origin P, so $\lambda\mathbf{u} \in U$. If also $\mathbf{w} = \overrightarrow{PY} \in U$, the point $X + Y - P$ lies in A (weights $1 + 1 - 1 = 1$) and equals $P + (\mathbf{u} + \mathbf{w})$, so $\mathbf{u} + \mathbf{w} \in U$. By Theorem 1.2.1, U is a subspace, and $A = P + U$ by construction.

(a) Let $X, Y \in A$. Then $\overrightarrow{XY} = \overrightarrow{XP} + \overrightarrow{PY} \in U$ by Chasles, since U is closed under negation and addition; so $\{\overrightarrow{XY} : X, Y \in A\} \subseteq U$. Conversely each $\mathbf{u} \in U$ is $\overrightarrow{PX}$ for some $X \in A$, and $P \in A$. Hence the two sets are equal, and the right-hand side mentions only A.

(b) Let $Q \in A$. For $X \in A$ we have $\overrightarrow{QX} \in \vec{A}$ by (a), so $A \subseteq Q + \vec{A}$; and for $\mathbf{u} \in \vec{A}$, writing $\mathbf{u} = \overrightarrow{XY}$ with $X, Y \in A$, the point $Q + \mathbf{u}$ is the affine combination $Q + Y - X$ of points of A, hence lies in A. So $A = Q + \vec{A}$. Finally the restricted difference map takes values in $\vec{A}$ by (a), Chasles is inherited, and for fixed $P \in A$ the map $X \mapsto \overrightarrow{PX}$ is a bijection $A \to \vec{A}$, being the restriction of the bijection of (AS2) to $A = P + \vec{A}$. So (AS1) and (AS2) hold and A is an affine space with direction space $\vec{A}$.

■

Over $\mathbb{R}$, with $\mathcal{A} = V$, a flat is exactly Chapter 17's affine subspace of V (Definition 17.1.5 (b)), and the two dimensions agree: Chapter 17 also reads the subspace off the coset as the set of differences. Chapter 4's **affine hyperplane** $\mathbf{p} + H$ (the paragraph before Proposition 4.6.4) is the case $\dim A = n - 1$ in $\mathbb{A}^n(F)$. A one-point set $\{P\} = P + \{\mathbf{0}\}$ is a flat, and $\mathcal{A} = P + V$ is a flat: the two degenerate cases.

A non-example, by minimal change. A line is a flat; the union of two lines is not. Let $X = \{(x, y) \in \mathbb{A}^2 : xy = 0\}$, the union of the two coordinate axes. It is non-empty, and it contains every affine combination of points taken from one axis, each axis being a flat. But Definition 21.2.1 asks for all of them: the points $P = (1, 0)$ and $Q = (0, 1)$ lie in X, the weights of $\frac{1}{2}P + \frac{1}{2}Q$ add up to 1, and $\frac{1}{2}P + \frac{1}{2}Q = \left(\frac{1}{2}, \frac{1}{2}\right)$ has $xy = \frac{1}{4} \neq 0$. So the closure clause fails for one pair of points, and X is not a coset of a subspace, although it is a union of two of them.

Proposition 21.2.2 — Intersections of Flats

Let $(A_i)_{i \in I}$ be a non-empty family of flats of $\mathcal{A}$ and put $A = \bigcap_{i \in I} A_i$. If $A \neq \emptyset$, then A is a flat and $\vec{A} = \bigcap_{i \in I} \vec{A}_i$.

Proof. Suppose $A \neq \emptyset$ and fix $P \in A$. If $P_1, \dots, P_k \in A$ and $\sum_j t_j = 1$, then the point $\sum_j t_j P_j$ lies in each A_i, because each A_i is a flat containing all the P_j; so it lies in A. Hence A is a flat. By Proposition 21.2.1 (b), $A_i = P + \vec{A}_i$ for each i and $A = P + \vec{A}$, so

$$\vec{A} = \{\overrightarrow{PX} : X \in A\} = \bigcap_{i \in I} \{\overrightarrow{PX} : X \in A_i\} = \bigcap_{i \in I} \vec{A}_i,$$

where the middle equality holds because $X \mapsto \overrightarrow{PX}$ is injective (AS2).

■

Since $\mathcal{A}$ itself is a flat containing every subset, the following is well defined.

Definition 21.2.2 — Join of Flats

Let A, B be flats of $\mathcal{A}$. Their **join** $A \vee B$ is the intersection of all flats of $\mathcal{A}$ containing $A \cup B$.

The intersection contains A, so it is non-empty, and it is a flat by Proposition 21.2.2: $A \vee B$ is the **smallest** flat containing both. A single point P is a flat, and we write $P \vee Q$, $A \vee P$ for joins in which a one-point flat $\{P\}$ appears. This is the affine analogue of $U + W$, and Chapter 17's affine hull is the same construction over $\mathbb{R}$ (Proposition 17.1.4).

Parallelism is what an affine space has and a vector space does not notice.

Definition 21.2.3 — Parallel Flats

Two flats A, B of $\mathcal{A}$ are **parallel**, written $A \parallel B$, if $\vec{A} = \vec{B}$.

Proposition 21.2.3 — Parallelism

Parallelism is an equivalence relation on the set of flats of $\mathcal{A}$. Two parallel flats are either equal or disjoint, and each equivalence class consists of the flats $P + U$, $P \in \mathcal{A}$, for one fixed subspace U.

Proof. Equality of direction spaces is an equivalence relation, so $\parallel$ is one. Let $A \parallel B$ with common direction U, and suppose $X \in A \cap B$. Then $A = X + U = B$ by Proposition 21.2.1 (b). So A and B are equal or disjoint. Finally, the flats with direction space U are exactly the sets $P + U$ with $P \in \mathcal{A}$, again by Proposition 21.2.1.

■

Parallel flats have the same dimension. Some authors also call a line parallel to a plane containing its direction; we do not, and we say "$\vec{A} \subseteq \vec{B}$" when we mean that.

21.2.2 When two flats meet, and how big their join is

Here is the central computation of the section. Two subspaces of a vector space always meet, in $\mathbf{0}$ at least. Two flats need not, and the dimension formula splits accordingly.

Theorem 21.2.4 — Intersection and Join of Two Flats

Let A, B be flats of $\mathcal{A}$, and choose $P \in A$ and $Q \in B$. Parts (a) and (b) need no hypothesis on $\dim \mathcal{A}$.

(a) $A \vee B = P + \big(\vec{A} + \vec{B} + \operatorname{span}(\overrightarrow{PQ})\big)$.

(b) $A \cap B \neq \emptyset$ if and only if $\overrightarrow{PQ} \in \vec{A} + \vec{B}$; and then $A \cap B$ is a flat whose direction space is $\vec{A} \cap \vec{B}$.

(c) Let $\dim \mathcal{A} = n$ be finite. If $A \cap B \neq \emptyset$, then

$$\dim(A \vee B) = \dim A + \dim B - \dim(A \cap B).$$

If $A \cap B = \emptyset$, then

$$\dim(A \vee B) = \dim A + \dim B - \dim(\vec{A} \cap \vec{B}) + 1.$$

(d) Let $\dim \mathcal{A} = n$ be finite. If $A \cap B = \emptyset$, there is a hyperplane H of V with $A \subseteq P + H$ and $B \subseteq Q + H$, and the two flats $P + H$, $Q + H$ are parallel, distinct and disjoint.

Idea. Everything is read off from one subspace, $W = \vec{A} + \vec{B} + \operatorname{span}(\overrightarrow{PQ})$. The three summands are forced: the join must contain the directions of A and of B, and it must contain a way of getting from A to B. Whether the third summand is already inside the first two is exactly whether A and B meet — and that one extra dimension, present precisely when they miss each other, is the whole difference between (c)'s two cases.

Proof. Put $W = \vec{A} + \vec{B} + \operatorname{span}(\overrightarrow{PQ})$, a subspace of V, and $C = P + W$, a flat by Proposition 21.2.1.

(a) First, $A \cup B \subseteq C$. Indeed $A = P + \vec{A} \subseteq P + W$. And each point of B is $Q + \mathbf{b}$ with $\mathbf{b} \in \vec{B}$, which equals $P + (\overrightarrow{PQ} + \mathbf{b})$ by Lemma 21.1.1 (b), and $\overrightarrow{PQ} + \mathbf{b} \in W$. So C is one of the flats being intersected in Definition 21.2.2, whence $A \vee B \subseteq C$. Conversely, $A \vee B$ is a flat containing P, so $A \vee B = P + U$ by Proposition 21.2.1 (b), where U is the direction space of $A \vee B$. Since $A \subseteq A \vee B$ and $P \in A$, part (a) of that proposition gives $\vec{A} \subseteq U$. Since $Q \in A \vee B$, also $\overrightarrow{PQ} \in U$. And for $\mathbf{b} \in \vec{B}$ the point $Q + \mathbf{b}$ lies in $B \subseteq A \vee B$, so $\overrightarrow{PQ} + \mathbf{b} = \overrightarrow{P(Q + \mathbf{b})} \in U$, and therefore $\mathbf{b} \in U$. Hence $W \subseteq U$, that is, $C \subseteq A \vee B$. The two inclusions give (a).

(b) ($\Leftarrow$) Suppose $\overrightarrow{PQ} = \mathbf{a} + \mathbf{b}$ with $\mathbf{a} \in \vec{A}$, $\mathbf{b} \in \vec{B}$. Put $X = P + \mathbf{a}$, a point of A. Then

$$\overrightarrow{QX} = \overrightarrow{QP} + \overrightarrow{PX} = -(\mathbf{a} + \mathbf{b}) + \mathbf{a} = -\mathbf{b} \in \vec{B},$$

so $X \in Q + \vec{B} = B$. Hence $X \in A \cap B$.
($\Rightarrow$) If $X \in A \cap B$, then $\overrightarrow{PX} \in \vec{A}$ and $\overrightarrow{XQ} \in \vec{B}$ by Proposition 21.2.1 (a), so

$\overrightarrow{PQ} = \overrightarrow{PX} + \overrightarrow{XQ} \in \vec{A} + \vec{B}$. The last clause is Proposition 21.2.2 applied to the two flats A and B.

(c) *Case 1:* $A \cap B \neq \emptyset$. By (b), $\overrightarrow{PQ} \in \vec{A}+\vec{B}$, so $W = \vec{A}+\vec{B}$. By (a) and Theorem 1.7.3,

$$\begin{aligned}\dim(A \vee B) &= \dim(\vec{A} + \vec{B}) \\ &= \dim \vec{A} + \dim \vec{B} - \dim(\vec{A} \cap \vec{B}),\end{aligned}$$

and $\dim(\vec{A} \cap \vec{B}) = \dim(A \cap B)$ by (b), which is the first formula.
Case 2: $A \cap B = \emptyset$. By (b), $\overrightarrow{PQ} \notin \vec{A} + \vec{B}$; in particular $\overrightarrow{PQ} \neq \mathbf{0}$. Then

$$\operatorname{span}(\overrightarrow{PQ}) \cap (\vec{A} + \vec{B}) = \{\mathbf{0}\},$$

since a non-zero $\lambda\overrightarrow{PQ}$ lying in $\vec{A} + \vec{B}$ would give $\overrightarrow{PQ} = \lambda^{-1}(\lambda\overrightarrow{PQ}) \in \vec{A} + \vec{B}$, λ being non-zero and hence invertible. So Theorem 1.7.3 applied to the two subspaces $\vec{A} + \vec{B}$ and $\operatorname{span}(\overrightarrow{PQ})$ gives $\dim W = \dim(\vec{A} + \vec{B}) + 1$, and one more application, as in Case 1, gives the second formula.

(d) Put $U = \vec{A} + \vec{B}$ and $r = \dim U$. By (b), $\overrightarrow{PQ} \notin U$, so appending $\overrightarrow{PQ}$ to a basis $(\mathbf{u}_1, \dots, \mathbf{u}_r)$ of U leaves an independent list (Lemma 1.5.3). Extend it to a basis

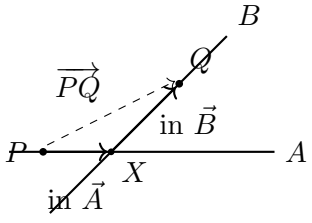
$$(\mathbf{u}_1, \dots, \mathbf{u}_r,\ \overrightarrow{PQ},\ \mathbf{w}_1, \dots, \mathbf{w}_{n-r-1})$$

of V by Theorem 1.6.5, and let $H = \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_r, \mathbf{w}_1, \dots, \mathbf{w}_{n-r-1})$. Then $\dim H = n - 1$, so $\dim(V/H) = 1$ by Theorem 3.9.5 and H is a hyperplane (Definition 4.5.2). Now $\vec{A} \subseteq U \subseteq H$ gives $A = P + \vec{A} \subseteq P + H$, and likewise $B \subseteq Q + H$. The flats $P + H$ and $Q + H$ are parallel by Definition 21.2.3. They are distinct: if they were equal, then $Q \in P + H$ would give $\overrightarrow{PQ} \in H$, contradicting the independence of the displayed basis. Being parallel and distinct, they are disjoint by Proposition 21.2.3. This proves the theorem.

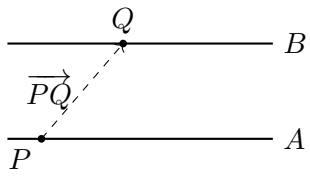
■

The two formulas in (c) are best read side by side. When the flats meet, the count is the subspace count of Theorem 1.7.3, with $A \cap B$ in the role of $\vec{A} \cap \vec{B}$. When they miss, the correction term is taken among the **directions**, where the flats always do meet, and a $+1$ is paid for the displacement that carries one flat to the other.

Part (b) is what the two pictures below show. On the left the displacement $\overrightarrow{PQ}$ splits as a step inside $\vec{A}$ followed by a step inside $\vec{B}$, and the flats meet; on the right it does not split, so it contributes a direction of its own to the join.



$A \cap B \neq \emptyset$



$A \cap B = \emptyset$

Example. (Two lines in space, twice)

In $\mathbb{A}^3$ let

$$A = (1,0,0) + \operatorname{span}\big((1,1,0)\big),$$
$$B = (0,0,1) + \operatorname{span}\big((1,-1,0)\big),$$
$$B' = (0,0,1) + \operatorname{span}\big((1,1,0)\big).$$

Decide in each case whether the lines meet, and compute $\dim(A \vee B)$ and $\dim(A \vee B')$.

Solution. Here $P = (1,0,0)$, $Q = (0,0,1)$ and $\overrightarrow{PQ} = (-1,0,1)$.

A and B. The directions $(1,1,0)$ and $(1,-1,0)$ are independent, and $\vec{A}+\vec{B}$ is the plane of vectors with third coordinate 0. Since $\overrightarrow{PQ} = (-1,0,1)$ has third coordinate 1, it is not in $\vec{A}+\vec{B}$, so $A \cap B = \emptyset$ by Theorem 21.2.4 (b): the lines are **skew**, that is, disjoint and not parallel. (Directly: $(1+s, s, 0) = (t, -t, 1)$ forces $0 = 1$.) Also $\vec{A} \cap \vec{B} = \{\mathbf{0}\}$, the two directions being independent. The second formula of (c) gives

$$\dim(A \vee B) = 1 + 1 - 0 + 1 = 3,$$

so $A \vee B = \mathbb{A}^3$: two skew lines span the whole space.

A and B'. Now $\vec{A} = \vec{B'}$, so the lines are parallel, and they are distinct because $\overrightarrow{PQ} = (-1,0,1) \notin \vec{A}$; hence they are disjoint (Proposition 21.2.3). Here $\vec{A} \cap \vec{B'} = \vec{A}$ has dimension 1, so

$$\dim(A \vee B') = 1 + 1 - 1 + 1 = 2,$$

and $A \vee B'$ is the plane $(1,0,0) + \operatorname{span}\big((1,1,0),(-1,0,1)\big)$, by part (a).

Warning. **There is no convention for $\dim \emptyset$ that makes one formula do both cases.** It is tempting to set $\dim \emptyset = -1$ and keep writing $\dim(A \vee B) = \dim A + \dim B - \dim(A \cap B)$. For the skew lines of Example (Two lines in space, twice) that gives $1 + 1 - (-1) = 3$, which is right; for the parallel lines A and B' it gives 3 as well, and the correct answer is 2. The two disjoint cases differ in $\dim(\vec{A} \cap \vec{B})$, which the empty intersection cannot record. Use the second formula of Theorem 21.2.4 (c), and always check first whether the flats meet.

Quick check. In $\mathbb{A}^4$, let A and B be planes (flats of dimension 2) with $\vec{A} \cap \vec{B} = \{\mathbf{0}\}$. Must they meet?

Solution. Yes. By Theorem 1.7.3, $\dim(\vec{A} + \vec{B}) = 2 + 2 - 0 = 4 = \dim V$, so $\vec{A} + \vec{B} = V$ by Theorem 1.6.8. Hence $\overrightarrow{PQ} \in \vec{A} + \vec{B}$ for any $P \in A$, $Q \in B$, and Theorem 21.2.4 (b) gives $A \cap B \neq \emptyset$. (The dimension formula agrees: the disjoint case would predict $2 + 2 - 0 + 1 = 5 > 4$, which is impossible.) Their intersection is then a single point, since its direction space is $\vec{A} \cap \vec{B} = \{\mathbf{0}\}$.

21.2.3 Affine frames and barycentric coordinates

To put coordinates on an n-dimensional vector space we choose n vectors. To put coordinates on an n-dimensional affine space we must also say where the origin is, so we choose $n+1$ points — and if we refuse to single out one of them, the coordinates come out symmetric in all $n+1$.

That symmetry is what makes the centroid computation below one line.

Chapter 17 §02 defined a list $(\mathbf{x}_0, \dots, \mathbf{x}_m)$ in a real vector space to be **affinely independent** when the only scalars with $\sum_i \lambda_i = 0$ and $\sum_i \lambda_i \mathbf{x}_i = \mathbf{0}$ are all zero (Definition 17.2.1). By Definition 21.1.2 (b) the expression $\sum_i \lambda_i P_i$ is a well-defined vector for points of an affine space whenever $\sum_i \lambda_i = 0$, so the same words apply here verbatim. The next lemma is Lemma 17.2.1 (a) in that setting; its proof uses nothing about $\mathbb{R}$, so we give it again over an arbitrary field.

Lemma 21.2.5 — Affine Independence by Differences

Let $P_0, P_1, \dots, P_m \in \mathcal{A}$. The following are equivalent.

(a) The only $\lambda_0, \dots, \lambda_m \in F$ with $\sum_{i=0}^{m} \lambda_i = 0$ and $\sum_{i=0}^{m} \lambda_i P_i = \mathbf{0}$ are $\lambda_0 = \cdots = \lambda_m = 0$.

(b) The list $(\overrightarrow{P_0P_1}, \dots, \overrightarrow{P_0P_m})$ is linearly independent in V.

A list satisfying these is called **affinely independent**. Condition (a) does not mention P_0 specially, so (b) holds with any P_j in place of P_0 as soon as it holds for one.

Proof. By Definition 21.1.2 (b) computed with origin P_0, and since $\overrightarrow{P_0P_0} = \mathbf{0}$,

$$\sum_{i=0}^{m} \lambda_i P_i = \sum_{i=0}^{m} \lambda_i \overrightarrow{P_0P_i} = \sum_{i=1}^{m} \lambda_i \overrightarrow{P_0P_i}.$$

Given $\lambda_1, \dots, \lambda_m$, the condition $\sum_{i=0}^{m} \lambda_i = 0$ holds for exactly one λ_0, namely $\lambda_0 = -\sum_{i \geq 1} \lambda_i$; and $(\lambda_0, \dots, \lambda_m)$ is the zero list exactly when $(\lambda_1, \dots, \lambda_m)$ is. So the relations forbidden by (a) correspond, one for one, to the non-trivial linear relations among $\overrightarrow{P_0P_1}, \dots, \overrightarrow{P_0P_m}$, and (a) holds if and only if there are none, which is (b). ∎

Over $\mathbb{R}$ with $\mathcal{A} = V$ this is Lemma 17.2.1 (a), and Chapter 17's warning applies unchanged: affine independence is **not** linear independence. The list $(\mathbf{0}, \mathbf{e}_1, \mathbf{e}_2)$ in $\mathbb{R}^2$ is linearly dependent and affinely independent, which is why the count below is $n + 1$ and not n.

Definition 21.2.4 — Affine Frame

Let $\dim \mathcal{A} = n$. An **affine frame** of $\mathcal{A}$ is a list $(P_0, P_1, \dots, P_n)$ of $n + 1$ affinely independent points of $\mathcal{A}$.

By Lemma 21.2.5 the list $(\overrightarrow{P_0P_1}, \dots, \overrightarrow{P_0P_n})$ is then independent with $n = \dim V$ entries, hence a basis of V (Theorem 1.6.4); conversely, if it is a basis, the frame condition holds. So an affine frame is "a point together with a basis", written symmetrically. In $\mathbb{A}^n(F)$ the **standard frame** is $(\mathbf{0}, \mathbf{e}_1, \dots, \mathbf{e}_n)$.

Theorem 21.2.6 — Barycentric Coordinates

Let $\dim \mathcal{A} = n$ and let $(P_0, \dots, P_n)$ be an affine frame of $\mathcal{A}$. For every $X \in \mathcal{A}$ there are

unique scalars $t_0, \dots, t_n \in F$ with

$$t_0 + t_1 + \cdots + t_n = 1 \qquad \text{and} \qquad X = \sum_{i=0}^{n} t_i P_i.$$

They are called the **barycentric coordinates** of X with respect to the frame.

Idea. Existence is the basis expansion of $\overrightarrow{P_0X}$, with t_0 invented to make the weights add up to 1. Uniqueness is affine independence: the difference of two weight lists is an affine dependence.

Proof. Existence. The list $(\overrightarrow{P_0P_1}, \dots, \overrightarrow{P_0P_n})$ is a basis of V, so there are unique $t_1, \dots, t_n \in F$ with $\overrightarrow{P_0X} = \sum_{i=1}^{n} t_i \overrightarrow{P_0P_i}$ (Theorem 1.5.1). Put $t_0 = 1 - (t_1 + \cdots + t_n)$, so that $\sum_{i=0}^{n} t_i = 1$. Computing the affine combination with origin P_0,

$$\sum_{i=0}^{n} t_i P_i = P_0 + \sum_{i=0}^{n} t_i \overrightarrow{P_0P_i} = P_0 + \overrightarrow{P_0X} = X.$$

Uniqueness. Suppose $\sum_i t_i P_i = X = \sum_i t'_i P_i$ with both weight lists summing to 1, and put $\lambda_i = t_i - t'_i$. Then $\sum_i \lambda_i = 0$, so $\sum_i \lambda_i P_i$ is the vector $\sum_i \lambda_i \overrightarrow{P_0P_i}$ of Definition 21.1.2 (b), and computing both combinations with origin P_0 gives

$$\sum_i \lambda_i \overrightarrow{P_0P_i} = \overrightarrow{P_0X} - \overrightarrow{P_0X} = \mathbf{0}.$$

By Lemma 21.2.5 (a), every $\lambda_i = 0$. This proves the theorem.

■

Barycentric coordinates come as a **list**, not as separate numbers: they are pinned down only by the requirement that they add up to 1, so no one of them means anything on its own. Their virtue is that the frame's points are treated alike: P_j has coordinates $(0, \dots, 1, \dots, 0)$ with the 1 in slot j, for every j.

Example. (Reading a triangle)

In $\mathbb{A}^2$ take the frame $P_0 = (0,0)$, $P_1 = (4,0)$, $P_2 = (0,3)$.

(a) Check that it is a frame, and find the barycentric coordinates (Theorem 21.2.6) of $X = (1,1)$.

(b) Find the point with barycentric coordinates $(\frac{1}{2}, \frac{1}{4}, \frac{1}{4})$.

(c) Describe the line $P_1 \vee P_2$ in barycentric coordinates.

Solution.

(a) $\overrightarrow{P_0P_1} = (4,0)$ and $\overrightarrow{P_0P_2} = (0,3)$ are independent, so by Lemma 21.2.5 the list is affinely independent, and three points in a plane make a frame. For $X = (1,1)$: from $(1,1) = t_1(4,0) + t_2(0,3)$ we get $t_1 = \frac{1}{4}$ and $t_2 = \frac{1}{3}$, so $t_0 = 1 - \frac{1}{4} - \frac{1}{3} = \frac{5}{12}$. The coordinates are $(\frac{5}{12}, \frac{1}{4}, \frac{1}{3})$. **Check:** $\frac{5}{12}(0,0) + \frac{1}{4}(4,0) + \frac{1}{3}(0,3) = (1,1)$, and

$\frac{5}{12} + \frac{3}{12} + \frac{4}{12} = 1$.

(b) $\frac{1}{2}(0,0) + \frac{1}{4}(4,0) + \frac{1}{4}(0,3) = \left(1, \frac{3}{4}\right)$.

(c) The join of the two distinct points P_1, P_2 is $P_1 + \operatorname{span}(\overrightarrow{P_1P_2})$ by Theorem 21.2.4 (a), a line. Its points are the affine combinations $(1-t)P_1 + tP_2$, whose barycentric coordinates are $(0, 1-t, t)$; conversely a point with $t_0 = 0$ is such a combination. So $P_1 \vee P_2 = \{t_0 = 0\}$. The point X of (a) has $t_0 = \frac{5}{12} \neq 0$ and so is not on it.

The next result is the advertisement for the whole apparatus: a classical theorem of plane geometry, proved in one line of arithmetic with weights.

Proposition 21.2.7 — The Medians Meet at the Centroid

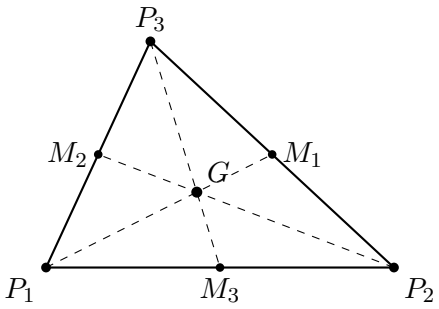
Let F be a field in which $2 \neq 0$ and $3 \neq 0$, let $\mathcal{A}$ be an affine space over F, and let (P_1, P_2, P_3) be an affinely independent list in $\mathcal{A}$. Put

$$M_1 = \tfrac{1}{2}P_2 + \tfrac{1}{2}P_3, \qquad M_2 = \tfrac{1}{2}P_1 + \tfrac{1}{2}P_3, \qquad M_3 = \tfrac{1}{2}P_1 + \tfrac{1}{2}P_2,$$

the **midpoints** of the sides, and let $m_i = P_i \vee M_i$ be the **medians**. Then m_1, m_2, m_3 are lines meeting in exactly one point, the **centroid**

$$G = \tfrac{1}{3}P_1 + \tfrac{1}{3}P_2 + \tfrac{1}{3}P_3,$$

and $\overrightarrow{P_iG} = 2\,\overrightarrow{GM_i}$ for each i.



Idea. Work in the plane $\pi = (P_1 \vee P_2) \vee P_3$, where (P_1, P_2, P_3) is an affine frame, and give every point its barycentric coordinates. A median is then the set of coordinate triples of one shape, and the three shapes have exactly one triple in common.

Proof. The three points are affinely independent, so $(\overrightarrow{P_1P_2}, \overrightarrow{P_1P_3})$ is independent by Lemma 21.2.5 and, by Theorem 21.2.4 (a) applied twice, $\pi := (P_1 \vee P_2) \vee P_3 = P_1 + \operatorname{span}(\overrightarrow{P_1P_2}, \overrightarrow{P_1P_3})$ is a plane in which (P_1, P_2, P_3) is an affine frame. All the points named lie in π, being affine combinations of P_1, P_2, P_3, so we may use the barycentric coordinates of Theorem 21.2.6 throughout; the weights $\frac{1}{2}$ and $\frac{1}{3}$ exist because 2 and 3 are non-zero, hence invertible, in F.

Each m_i is a line, and G lies on it. Take $i = 1$. In coordinates $P_1 = (1,0,0)$ and $M_1 = (0, \frac{1}{2}, \frac{1}{2})$, so $P_1 \neq M_1$ by the uniqueness in Theorem 21.2.6, and $m_1 = P_1 \vee M_1 = P_1 + \operatorname{span}(\overrightarrow{P_1M_1})$ by Theorem 21.2.4 (a), a flat of dimension 1 because $\overrightarrow{P_1M_1} \neq \mathbf{0}$. Its

points are the affine combinations $(1-s)P_1 + sM_1$, $s \in F$, with coordinates

$$\big(1-s,\ \tfrac{s}{2},\ \tfrac{s}{2}\big).$$

At $s = \tfrac{2}{3}$ this is $\big(\tfrac{1}{3},\tfrac{1}{3},\tfrac{1}{3}\big)$, the coordinate triple of G. So $G \in m_1$, and by the same computation with the indices permuted, $G \in m_2$ and $G \in m_3$.

No other common point. A point of $m_1 \cap m_2$ has coordinates $(1-s,\tfrac{s}{2},\tfrac{s}{2})$ and $(\tfrac{s'}{2},1-s',\tfrac{s'}{2})$ for some $s, s' \in F$. Uniqueness in Theorem 21.2.6 makes the two triples equal entry by entry. The third entries give $s = s'$, and then the first two give $1-s = \tfrac{s}{2}$, that is, $\tfrac{3}{2}s = 1$ and $s = \tfrac{2}{3}$. So $m_1 \cap m_2 = \{G\}$, and a fortiori $m_1 \cap m_2 \cap m_3 = \{G\}$.

The ratio. With origin P_1 we have $\overrightarrow{P_1M_1} = \tfrac{1}{2}\overrightarrow{P_1P_2} + \tfrac{1}{2}\overrightarrow{P_1P_3}$ and $\overrightarrow{P_1G} = \tfrac{1}{3}\overrightarrow{P_1P_2} + \tfrac{1}{3}\overrightarrow{P_1P_3}$, so $\overrightarrow{P_1G} = \tfrac{2}{3}\overrightarrow{P_1M_1}$ and $\overrightarrow{GM_1} = \overrightarrow{P_1M_1} - \overrightarrow{P_1G} = \tfrac{1}{3}\overrightarrow{P_1M_1}$. Hence $\overrightarrow{P_1G} = 2\overrightarrow{GM_1}$, and likewise for $i = 2, 3$. This proves the proposition.

■

Remark. The hypotheses on the field are not decoration. Over $\mathbb{F}_2$ there are no midpoints, because $\tfrac{1}{2}$ does not exist; over $\mathbb{F}_3$ there are midpoints but no centroid, because $\tfrac{1}{3}$ does not exist — and indeed in $\mathbb{A}^2(\mathbb{F}_3)$ the three medians of an affinely independent triple are parallel and pairwise disjoint, as Exercise C3 below computes.

21.2.4 An affine map is fixed by a frame

Barycentric coordinates make the next theorem immediate, and it is the affine counterpart of "a linear map is determined by its values on a basis".

Theorem 21.2.8 — An Affine Map Is Determined by a Frame

Let $\mathcal{A}$ have dimension n with affine frame $(P_0,\dots,P_n)$, let $\mathcal{B}$ be an affine space over the same field with direction space W, and let $Q_0,\dots,Q_n \in \mathcal{B}$ be **any** points. Then there is exactly one affine map $f\colon \mathcal{A} \to \mathcal{B}$ with $f(P_i) = Q_i$ for $i = 0,\dots,n$. Moreover f carries the barycentric coordinates of Theorem 21.2.6 across:

$$f\Big(\sum_{i=0}^{n} t_i P_i\Big) = \sum_{i=0}^{n} t_i Q_i \qquad \Big(\sum_i t_i = 1\Big).$$

Proof. Existence. The list $(\overrightarrow{P_0P_1},\dots,\overrightarrow{P_0P_n})$ is a basis of V, so by Theorem 3.1.6 there is a linear $T\colon V \to W$ with $T(\overrightarrow{P_0P_i}) = \overrightarrow{Q_0Q_i}$ for $i = 1,\dots,n$. Define $f(X) = Q_0 + T(\overrightarrow{P_0X})$; it is affine with $\vec{f} = T$ by Theorem 21.1.5 (c). Then $f(P_0) = Q_0 + T(\mathbf{0}) = Q_0$, and $f(P_i) = Q_0 + \overrightarrow{Q_0Q_i} = Q_i$.

Uniqueness. Let g be affine with $g(P_i) = Q_i$ for all i. By Theorem 21.1.5 (b),

$$\vec{g}(\overrightarrow{P_0P_i}) = \overrightarrow{g(P_0)g(P_i)} = \overrightarrow{Q_0Q_i} = T(\overrightarrow{P_0P_i}) \qquad (i = 1,\dots,n),$$

so $\vec{g}$ and T agree on a basis and are equal (Theorem 3.1.5). Hence $g(X) = g(P_0) + \vec{g}(\overrightarrow{P_0X}) = Q_0 + T(\overrightarrow{P_0X}) = f(X)$ for every X.

The displayed identity is Definition 21.1.3 applied to $\sum_i t_i P_i$, using $f(P_i) = Q_i$.

■

So $n+1$ points in the right position determine an affine map of an n-dimensional space, and prescribe it freely. Fewer points never do, and not because our proof is weak.

Proposition 21.2.9 — Points inside a proper flat do not determine an affine map

Let $\dim \mathcal{A} = n \geq 1$ and let $S \subseteq \mathcal{A}$ be contained in a flat A with $\dim A < n$ — for instance, any set of at most n points. Then there are two **distinct** affine maps $\mathcal{A} \to \mathcal{A}$ that agree at every point of S.

Proof. Let $P \in A$ and let $(\mathbf{u}_1, \ldots, \mathbf{u}_d)$ be a basis of $\vec{A}$, where $d = \dim A < n$. Extend it to a basis $(\mathbf{u}_1, \ldots, \mathbf{u}_d, \mathbf{w}_1, \ldots, \mathbf{w}_{n-d})$ of V (Theorem 1.6.5); since $d < n$, the vector $\mathbf{w}_1$ exists. Let $T\colon V \to V$ be the linear map fixing each $\mathbf{u}_j$ and each $\mathbf{w}_k$ with $k \geq 2$, and sending $\mathbf{w}_1$ to $\mathbf{0}$ (Theorem 3.1.6), and put $g(X) = P + T(\overrightarrow{PX})$, an affine map by Theorem 21.1.5 (c).

For $X \in A$ we have $\overrightarrow{PX} \in \vec{A} = \operatorname{span}(\mathbf{u}_1, \ldots, \mathbf{u}_d)$, on which T is the identity, so $g(X) = P + \overrightarrow{PX} = X$. Hence g agrees with $\mathrm{id}_{\mathcal{A}}$ on A, and so on S. But $g \neq \mathrm{id}_{\mathcal{A}}$, since $g(P + \mathbf{w}_1) = P + T(\mathbf{w}_1) = P \neq P + \mathbf{w}_1$ by Lemma 21.1.1 (c).

Finally, a non-empty set of at most n points does lie in such a flat. Put

$$D = P_0 + \operatorname{span}(\overrightarrow{P_0P_1}, \ldots, \overrightarrow{P_0P_m}).$$

This is the smallest flat containing $P_0, \ldots, P_m$: it is a flat by Proposition 21.2.1 and contains every P_i; and any flat containing all the P_i contains P_0, hence equals $P_0 + U$ with each $\overrightarrow{P_0P_i} \in U$, so it contains D by Theorem 1.3.1. Thus $\dim D \leq m$, and $m+1 \leq n$ gives $\dim D \leq n-1 < n$. (An empty S lies in the flat $\{P\}$ for any P.)

■

Example (Two points are not enough in the plane) is an instance of this proposition, with $n = 2$ and $S = \{(0,0), (1,0)\}$; it exhibits its own pair of maps rather than the pair the proof constructs. The moral is the count: $n+1$, never n. It is the same count that will govern projective transformations later in this chapter, where the answer turns out to be $n+2$.

21.2.5 A flat is a solution set

Chapter 2 produced flats as solution sets; Chapter 4 proved that every subspace of F^n is a null space. Putting the two together identifies the flats of $\mathbb{A}^n(F)$ completely.

Theorem 21.2.10 — Flats Are Exactly the Solution Sets

Let $A \subseteq \mathbb{A}^n(F)$ be non-empty and $0 \leq k \leq n$. The following are equivalent.

(a) A is a flat of dimension k.

(b) $A = \{\mathbf{x} \in F^n : \mathbf{M}\mathbf{x} = \mathbf{c}\}$ for some $\mathbf{M} \in M_{(n-k)\times n}(F)$ with linearly independent rows and some $\mathbf{c} \in F^{n-k}$.

In that case no system with fewer than $n-k$ equations has solution set A, and for $k < n$ the flat A is an intersection of exactly $n-k$ affine hyperplanes.

Idea. A flat is a coset $\mathbf{p}+U$ by Proposition 21.2.1, Chapter 4 turns U into a null space, and Chapter 2's "particular plus homogeneous" turns the coset into the solution set of the inhomogeneous system with the same matrix and right-hand side $\mathbf{M}\mathbf{p}$.

Proof.

(a) $\Rightarrow$ (b). By Proposition 21.2.1, $A = \mathbf{p} + U$ with $U = \vec{A}$ and $\dim U = k$. By Theorem 4.6.2 (a) there is $\mathbf{M} \in M_{(n-k)\times n}(F)$ with $\operatorname{nul}(\mathbf{M}) = U$ whose rows $\mathbf{a}_1^\top, \dots, \mathbf{a}_{n-k}^\top$ are the ones corresponding to a basis $(\varphi_{\mathbf{a}_1}, \dots, \varphi_{\mathbf{a}_{n-k}})$ of U^0 under the isomorphism $\mathbf{a} \mapsto \varphi_{\mathbf{a}}$ of Theorem 4.1.1; an injective linear map preserves independence (Theorem 3.2.5), so those rows are linearly independent. Put $\mathbf{c} = \mathbf{M}\mathbf{p}$. Then $\mathbf{p}$ solves $\mathbf{M}\mathbf{x} = \mathbf{c}$, so by Theorem 2.1.3 the solution set is $\mathbf{p} + \operatorname{nul}(\mathbf{M}) = \mathbf{p} + U = A$.

(b) $\Rightarrow$ (a). The set A is non-empty, so it has an element $\mathbf{p}$, and Theorem 2.1.3 gives $A = \mathbf{p} + \operatorname{nul}(\mathbf{M})$, a coset, hence a flat by Proposition 21.2.1 with $\vec{A} = \operatorname{nul}(\mathbf{M})$. The rows of $\mathbf{M}$ are independent, so $\operatorname{rank}\mathbf{M} = \dim \operatorname{row}(\mathbf{M}) = n-k$ by Theorem 2.5.5, and Theorem 2.5.7 gives $\dim A = \operatorname{nullity}(\mathbf{M}) = n - (n-k) = k$.

Minimality. Suppose $\mathbf{B} \in M_{m\times n}(F)$ and $\mathbf{d} \in F^m$ satisfy $\{\mathbf{x} : \mathbf{B}\mathbf{x} = \mathbf{d}\} = A$. Fix $\mathbf{p} \in A$. For any $\mathbf{x}$, $\mathbf{B}\mathbf{x} = \mathbf{d}$ holds if and only if $\mathbf{B}(\mathbf{x}-\mathbf{p}) = \mathbf{0}$, so $\mathbf{x} \in A$ if and only if $\mathbf{x} - \mathbf{p} \in \operatorname{nul}(\mathbf{B})$; that is, $A = \mathbf{p} + \operatorname{nul}(\mathbf{B})$. Comparing with $A = \mathbf{p} + \vec{A}$ and using Proposition 21.2.1 (a), $\operatorname{nul}(\mathbf{B}) = \vec{A} = U$. By Theorem 4.6.2 (b), $m \geq n-k$.

Hyperplanes. Let $k < n$ and write $\mathbf{a}_1^\top, \dots, \mathbf{a}_{n-k}^\top$ for the rows of a matrix $\mathbf{M}$ as in (b). Each $\varphi_{\mathbf{a}_i}$ vanishes on $U = \operatorname{nul}(\mathbf{M})$, hence lies in U^0 (Definition 4.2.1), and the $\varphi_{\mathbf{a}_i}$ are independent because the rows are and $\mathbf{a} \mapsto \varphi_{\mathbf{a}}$ is an isomorphism (Theorem 4.1.1); as $\dim U^0 = n-k$ by Theorem 4.2.2, they are a basis of U^0 (Theorem 1.6.4). So $\mathbf{M}$ is a matrix as in Theorem 4.6.2 (a), and Proposition 4.6.4 applied to U and $\mathbf{p}$ writes $A = \mathbf{p} + U$ as the intersection of the $n-k$ affine hyperplanes $\{\mathbf{x} : \mathbf{a}_i^\top \mathbf{x} = \mathbf{a}_i^\top \mathbf{p}\}$.

■

For $k = n$ the system is empty and $A = F^n$; for $k = 0$ it has n independent equations and A is a single point. In between, the count is the familiar one: **dimension counts parameters, codimension counts independent equations**, and now it holds for flats as it did for subspaces.

Example. (Equations for a plane in four-space)

In Example (Equations for a plane in $\mathbb{R}^4$) the subspace $U = \operatorname{span}\big((1,1,0,1),(0,1,1,1)\big)$ of $\mathbb{R}^4$ was found to be $\{\mathbf{x} : x_1 - x_2 + x_3 = 0,\ x_4 - x_2 = 0\}$. Find equations for the flat $A = \mathbf{p} + U$ with $\mathbf{p} = (1,0,0,0)$, and give two of its points.

Solution. Take $\mathbf{M} = \begin{pmatrix} 1 & -1 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{pmatrix}$, whose null space is U, and $\mathbf{c} = \mathbf{Mp} = (1, 0)$. By Theorem 21.2.10,

$$A = \{\mathbf{x} \in \mathbb{R}^4 : x_1 - x_2 + x_3 = 1, \quad x_4 - x_2 = 0\},$$

a flat of dimension $4 - 2 = 2$. Two points: $\mathbf{p} = (1, 0, 0, 0)$, with $1 - 0 + 0 = 1$ and $0 - 0 = 0$; and $\mathbf{p} + (1, 1, 0, 1) = (2, 1, 0, 1)$, with $2 - 1 + 0 = 1$ and $1 - 1 = 0$. By the minimality clause, no single equation cuts out A, since $n - k = 2$.

That closes the affine part of the chapter's foundations. Flats are cosets, they meet or they do not, their joins obey a two-case formula, they carry symmetric coordinates, and in $\mathbb{A}^n(F)$ they are the solution sets of linear systems. The one irritant is the second case of the join formula, and the reason two coplanar lines can fail to meet: in the affine plane, parallel lines have nowhere to intersect. The projective sections later in this chapter remove that exception by adding the missing points.

21.2.6 Exercises

21.2.6.1 A. Check your understanding

Exercise A1.

(a) Define a flat and its direction space, and say why the direction space does not depend on the point used to compute it.

(b) State both cases of the dimension formula for $\dim(A \vee B)$, and say which one applies to two distinct parallel planes in $\mathbb{A}^3$.

(c) True or false, with a reason: the intersection of two flats is a flat.

(d) What are the barycentric coordinates of P_2 with respect to the frame (P_0, P_1, P_2, P_3) of a three-dimensional affine space?

Solution.

(a) A flat is a non-empty subset closed under affine combinations (Definition 21.2.1); equivalently a coset $P + U$ with U a subspace of V (Proposition 21.2.1). Its direction space is $\vec{A} = \{\overrightarrow{XY} : X, Y \in A\}$, a description that mentions only A, so no choice of point enters.

(b) If $A \cap B \neq \emptyset$, $\dim(A \vee B) = \dim A + \dim B - \dim(A \cap B)$; if $A \cap B = \emptyset$, $\dim(A \vee B) = \dim A + \dim B - \dim(\vec{A} \cap \vec{B}) + 1$. Two distinct parallel planes in $\mathbb{A}^3$ are disjoint (Proposition 21.2.3), so the second applies: $2 + 2 - 2 + 1 = 3$, and their join is $\mathbb{A}^3$.

(c) False as stated, because the intersection may be empty, and the empty set is not a flat (Definition 21.2.1). It is true that a **non-empty** intersection of flats is a flat (Proposition 21.2.2). Two parallel lines in $\mathbb{A}^2$ give the counterexample.

(d) $(0, 0, 1, 0)$: the combination $0 \cdot P_0 + 0 \cdot P_1 + 1 \cdot P_2 + 0 \cdot P_3$ has weights summing to 1 and equals P_2, and the coordinates are unique by Theorem 21.2.6.

21.2.6.2 B. Practice

Exercise B1: Two flats in four-space.

In $\mathbb{A}^4$ let $A = (1,0,0,0) + \operatorname{span}\big((1,1,0,0),(0,0,1,1)\big)$, and let

$$B = (0,1,0,0) + \operatorname{span}\big((1,0,1,0)\big), \qquad B' = (2,1,0,0) + \operatorname{span}\big((1,0,1,0)\big).$$

For each of B and B', decide whether it meets A, and compute $\dim(A \vee \cdot)$. Justify your answers with Theorem 21.2.4.

Solution. Write $P = (1,0,0,0)$, $\vec{A} = \operatorname{span}\big((1,1,0,0),(0,0,1,1)\big)$ and $\vec{B} = \vec{B'} = \operatorname{span}\big((1,0,1,0)\big)$. The three spanning vectors are independent (the first two have disjoint supports, and $a(1,1,0,0) + b(0,0,1,1) = (1,0,1,0)$ would need $a = 1$ and $a = 0$), so $\dim(\vec{A} + \vec{B}) = 3$ and $\vec{A} \cap \vec{B} = \{\mathbf{0}\}$.

B. Here $Q = (0,1,0,0)$ and $\overrightarrow{PQ} = (-1,1,0,0)$. If $\overrightarrow{PQ} = a(1,1,0,0) + b(0,0,1,1) + c(1,0,1,0)$, the second coordinate gives $a = 1$ and the first gives $a + c = -1$, so $c = -2$; the third then gives $b + c = 0$, so $b = 2$, and the fourth gives $b = 0$, a contradiction. So $\overrightarrow{PQ} \notin \vec{A} + \vec{B}$ and $A \cap B = \emptyset$ by part (b) of the theorem. Part (c) gives $\dim(A \vee B) = 2 + 1 - 0 + 1 = 4$, so $A \vee B = \mathbb{A}^4$.

B'. Here $Q' = (2,1,0,0)$ and $\overrightarrow{PQ'} = (1,1,0,0) \in \vec{A} \subseteq \vec{A} + \vec{B'}$, so $A \cap B' \neq \emptyset$. Following the proof of part (b), the meeting point is $P + (1,1,0,0) = (2,1,0,0) = Q'$, and indeed $Q' \in A \cap B'$. By part (b) the direction space of $A \cap B'$ is $\vec{A} \cap \vec{B'} = \{\mathbf{0}\}$, so the intersection is the single point $\{Q'\}$, of dimension 0, and $\dim(A \vee B') = 2 + 1 - 0 = 3$.

Exercise B2: Barycentric arithmetic.

In $\mathbb{A}^2$ take the frame $P_0 = (1,1)$, $P_1 = (3,1)$, $P_2 = (1,4)$.

(a) Verify that it is a frame.

(b) Find the barycentric coordinates (Theorem 21.2.6) of $X = (2,2)$.

(c) Find the centroid of (P_0, P_1, P_2) in ordinary coordinates, and check its barycentric coordinates.

Solution.

(a) $\overrightarrow{P_0P_1} = (2,0)$ and $\overrightarrow{P_0P_2} = (0,3)$ are independent, so the list is affinely independent by Lemma 21.2.5, and it has $3 = 2 + 1$ entries.

(b) $\overrightarrow{P_0X} = (1,1) = t_1(2,0) + t_2(0,3)$ gives $t_1 = \frac{1}{2}$, $t_2 = \frac{1}{3}$, so $t_0 = 1 - \frac{1}{2} - \frac{1}{3} = \frac{1}{6}$. The coordinates are $\big(\frac{1}{6}, \frac{1}{2}, \frac{1}{3}\big)$. **Check:** $\frac{1}{6}(1,1) + \frac{1}{2}(3,1) + \frac{1}{3}(1,4) = \big(\frac{1}{6} + \frac{3}{2} + \frac{1}{3},\ \frac{1}{6} + \frac{1}{2} + \frac{4}{3}\big) = (2,2)$.

(c) $G = \frac{1}{3}\big((1,1) + (3,1) + (1,4)\big) = \big(\frac{5}{3}, 2\big)$. Its barycentric coordinates are $\big(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\big)$ by definition, and by uniqueness these are the only ones. **Check against (b)'s method:** $\overrightarrow{P_0G} = \big(\frac{2}{3}, 1\big) = \frac{1}{3}(2,0) + \frac{1}{3}(0,3)$, so $t_1 = t_2 = \frac{1}{3}$ and $t_0 = \frac{1}{3}$.

Exercise B3: From parameters to equations and back.

(a) Find a system of equations whose solution set is the line $A = (1,2,3) + \operatorname{span}\big((1,1,1)\big)$ in $\mathbb{A}^3$, using as few equations as possible.

(b) The set $B = \{\mathbf{x} \in \mathbb{R}^3 : x_1 + x_2 + x_3 = 6\}$ is a flat. Find its dimension, a point of it, and its direction space.

(c) Decide whether $A \subseteq B$, and compute $\dim(A \vee B)$.

Solution.

(a) Here $k = 1$ and $n = 3$, so Theorem 21.2.10 calls for $3-1 = 2$ equations, and no fewer will do. A functional $\mathbf{a}^\top \mathbf{x}$ vanishes on $\operatorname{span}((1,1,1))$ exactly when $a_1+a_2+a_3 = 0$; two independent such rows are $(1,-1,0)$ and $(0,1,-1)$. With $\mathbf{p} = (1,2,3)$ the right-hand sides are $1-2 = -1$ and $2-3 = -1$, so

$$A = \{\mathbf{x} : x_1 - x_2 = -1,\ x_2 - x_3 = -1\}.$$

Check: $\mathbf{p}$ satisfies both, and so does $\mathbf{p} + (1,1,1) = (2,3,4)$.

(b) One equation with a non-zero row, so $\dim B = 3 - 1 = 2$ by Theorem 21.2.10, a plane. The point $(6,0,0)$ lies in it, and $\vec{B} = \operatorname{nul}\begin{pmatrix}1 & 1 & 1\end{pmatrix} = \{\mathbf{x} : x_1+x_2+x_3 = 0\}$.

(c) $\mathbf{p} = (1,2,3)$ has $1+2+3 = 6$, so $\mathbf{p} \in B$; but $(1,1,1) \notin \vec{B}$, since $1+1+1 = 3 \neq 0$. So $A \not\subseteq B$, while $A \cap B \neq \emptyset$ (it contains $\mathbf{p}$). Since $\vec{A} \cap \vec{B} = \{\mathbf{0}\}$, the intersection is the single point $\{\mathbf{p}\}$ and $\dim(A \vee B) = 1 + 2 - 0 = 3$: the line and the plane together span $\mathbb{A}^3$.

21.2.6.3 C. Going deeper

Exercise C1: Affine maps and flats.

Let $f\colon \mathcal{A} \to \mathcal{B}$ be affine and let $A \subseteq \mathcal{A}$ be a flat.

(a) Prove that $f(A)$ is a flat of $\mathcal{B}$ whose direction space is $\vec{f}(\vec{A})$, and deduce $\dim f(A) \leq \dim A$.

(b) Prove that if $B \subseteq \mathcal{B}$ is a flat with $f^{-1}(B) \neq \emptyset$, then $f^{-1}(B)$ is a flat with direction space $(\vec{f})^{-1}(\vec{B})$.

(c) Hence prove that an **injective** affine map sends flats to flats of the same dimension, and lines to lines.

Solution.

(a) $f(A)$ is non-empty. Let $P \in A$, so $A = P + \vec{A}$ (Proposition 21.2.1). For $\mathbf{u} \in \vec{A}$, Theorem 21.1.5 (c) gives $f(P + \mathbf{u}) = f(P) + \vec{f}(\mathbf{u})$. Hence $f(A) = f(P) + \vec{f}(\vec{A})$, and $\vec{f}(\vec{A})$ is a subspace of W, being the image of the linear map $\vec{f}$ restricted to the subspace $\vec{A}$ (Theorem 3.2.2 applied to that restriction). So $f(A)$ is a flat by Proposition 21.2.1, with the stated direction space, and $\dim f(A) = \dim \vec{f}(\vec{A}) \leq \dim \vec{A} = \dim A$, because the images of a basis of $\vec{A}$ span $\vec{f}(\vec{A})$ (Theorem 3.2.4) and a spanning list is at least as long as the dimension (Theorem 1.6.3 (b)).

(b) Let $P \in f^{-1}(B)$, so $f(P) \in B$. For $\mathbf{u} \in V$, $f(P + \mathbf{u}) = f(P) + \vec{f}(\mathbf{u})$ lies in $B = f(P) + \vec{B}$ exactly when $\vec{f}(\mathbf{u}) \in \vec{B}$. So $f^{-1}(B) = P + (\vec{f})^{-1}(\vec{B})$, and $(\vec{f})^{-1}(\vec{B})$ is a subspace: it contains $\mathbf{0}$ and is closed under linear combinations by linearity of $\vec{f}$ and the subspace test (Theorem 1.2.1). By Proposition 21.2.1, $f^{-1}(B)$ is a flat with that direction space.

(c) If f is injective, then $\vec{f}$ is injective: $\vec{f}(\mathbf{u}) = \mathbf{0}$ gives $f(P + \mathbf{u}) = f(P)$, hence

$P + \mathbf{u} = P$ and $\mathbf{u} = \mathbf{0}$. An injective linear map carries a basis of $\vec{A}$ to a linearly independent list (Theorem 3.2.5) that spans $\vec{f}(\vec{A})$, hence to a basis of it; so $\dim f(A) = \dim \vec{f}(\vec{A}) = \dim \vec{A} = \dim A$ by (a). A line has dimension 1, so its image is a flat of dimension 1, a line.

Exercise C2: The midpoint quadrilateral.

Let F be a field with $2 \neq 0$, let $\mathcal{A}$ be an affine space over F, and let $P_1, P_2, P_3, P_4 \in \mathcal{A}$ be any four points. Put $M_{12} = \frac{1}{2}P_1 + \frac{1}{2}P_2$, and define M_{23}, M_{34}, M_{41} likewise.

(a) Prove that $\overrightarrow{M_{12}M_{23}} = \overrightarrow{M_{41}M_{34}} = \frac{1}{2}\overrightarrow{P_1P_3}$.

(b) Deduce that if $M_{12}, M_{23}, M_{34}, M_{41}$ are distinct, then $M_{12} \vee M_{23}$ and $M_{41} \vee M_{34}$ are parallel lines, and likewise for the other pair of opposite sides: the four midpoints form a parallelogram.

(c) What does the statement say when P_1, P_2, P_3, P_4 are **not** coplanar, for instance in $\mathbb{A}^3$?

Solution.

(a) Fix any origin O and write $\mathbf{p}_i = \overrightarrow{OP_i}$. By Definition 21.1.2, $\overrightarrow{OM_{12}} = \frac{1}{2}(\mathbf{p}_1 + \mathbf{p}_2)$ and similarly for the others. Hence, by Proposition 21.1.3,

$$\overrightarrow{M_{12}M_{23}} = \tfrac{1}{2}(\mathbf{p}_2 + \mathbf{p}_3) - \tfrac{1}{2}(\mathbf{p}_1 + \mathbf{p}_2) = \tfrac{1}{2}(\mathbf{p}_3 - \mathbf{p}_1) = \tfrac{1}{2}\overrightarrow{P_1P_3},$$

and

$$\overrightarrow{M_{41}M_{34}} = \tfrac{1}{2}(\mathbf{p}_3 + \mathbf{p}_4) - \tfrac{1}{2}(\mathbf{p}_4 + \mathbf{p}_1) = \tfrac{1}{2}(\mathbf{p}_3 - \mathbf{p}_1).$$

The answer does not depend on O, as it must not.

(b) If $M_{12} \neq M_{23}$, the join $M_{12} \vee M_{23}$ is the line $M_{12} + \operatorname{span}(\overrightarrow{M_{12}M_{23}})$ by Theorem 21.2.4 (a). By (a) the two lines $M_{12} \vee M_{23}$ and $M_{41} \vee M_{34}$ have the same direction space $\operatorname{span}\big(\frac{1}{2}\overrightarrow{P_1P_3}\big)$, so they are parallel (Definition 21.2.3). Running (a) with the indices shifted by one gives $\overrightarrow{M_{23}M_{34}} = \overrightarrow{M_{12}M_{41}} = \frac{1}{2}\overrightarrow{P_2P_4}$, so the other two sides are parallel too.

(c) Nothing in (a) used coplanarity, so the conclusion holds for a skew quadrilateral in $\mathbb{A}^3$ as well: the four midpoints of a skew quadrilateral are coplanar and form a parallelogram. Four non-coplanar points are affinely independent: otherwise $(\overrightarrow{P_1P_2}, \overrightarrow{P_1P_3}, \overrightarrow{P_1P_4})$ would be dependent (Lemma 21.2.5) and span a subspace of dimension at most 2, putting all four points in a flat of dimension at most 2. The four midpoints are then distinct, since the difference of two of them is $\sum_i \lambda_i P_i$ with $\sum_i \lambda_i = 0$ and the λ_i not all zero — for M_{12} and M_{23} the weights are $\frac{1}{2}$ at P_1 and $-\frac{1}{2}$ at P_3 — hence is a non-zero vector; so (b) applies. The two parallel lines $M_{12} \vee M_{23}$ and $M_{41} \vee M_{34}$ are also distinct: were they equal, their common direction space would contain $\overrightarrow{M_{12}M_{41}}$, which is $\frac{1}{2}\overrightarrow{P_2P_4}$ by (b), so $\frac{1}{2}\overrightarrow{P_2P_4} = \mu \cdot \frac{1}{2}\overrightarrow{P_1P_3}$ for some $\mu \in F$ (Proposition 21.2.1 (a)) — a relation $\sum_i \lambda_i P_i = \mathbf{0}$ with weights summing to 0 and $-\frac{1}{2} \neq 0$ at P_2, again against affine independence. Their join is therefore a plane, of dimension $1 + 1 - 1 + 1 = 2$ by Theorem 21.2.4 (c), and it contains all four midpoints.

Exercise C3: Medians over the field with three elements.

Work in $\mathbb{A}^2(\mathbb{F}_3)$ with the affinely independent list $P_1 = (0,0)$, $P_2 = (1,0)$, $P_3 = (0,1)$. (Nothing is lost by this choice: by Theorem 21.2.8 any other affinely independent triple is carried to this one by an affine bijection, which preserves midpoints, being an affine combination, and carries lines to lines by Exercise (C1: Affine maps and flats).)

(a) Compute the three midpoints M_i and the three medians $m_i = P_i \vee M_i$.

(b) Prove that the three medians are pairwise parallel and pairwise disjoint, so that Proposition 21.2.7 fails over $\mathbb{F}_3$.

(c) Explain which step of the proof of Proposition 21.2.7 breaks, and why the hypothesis $3 \neq 0$ cannot be dropped.

Solution.

(a) In $\mathbb{F}_3$ we have $2^{-1} = 2$, since $2 \cdot 2 = 4 = 1$. So

$$\begin{aligned} M_1 &= 2P_2 + 2P_3 = 2(1,0) + 2(0,1) = (2,2), \\ M_2 &= 2P_1 + 2P_3 = (0,2), \\ M_3 &= 2P_1 + 2P_2 = (2,0). \end{aligned}$$

Then $\overrightarrow{P_1M_1} = (2,2)$, $\overrightarrow{P_2M_2} = (0,2) - (1,0) = (2,2)$ and $\overrightarrow{P_3M_3} = (2,0) - (0,1) = (2,2)$. So

$$\begin{aligned} m_1 &= (0,0) + \operatorname{span}\big((2,2)\big), \\ m_2 &= (1,0) + \operatorname{span}\big((2,2)\big), \\ m_3 &= (0,1) + \operatorname{span}\big((2,2)\big). \end{aligned}$$

(b) All three have the same direction space $\operatorname{span}((2,2)) = \operatorname{span}((1,1))$, so they are parallel (Definition 21.2.3). They are distinct: $\overrightarrow{P_1P_2} = (1,0) \notin \operatorname{span}((1,1))$, and likewise for the other two pairs, so no two of them share a point by Proposition 21.2.1 (b). Distinct parallel flats are disjoint (Proposition 21.2.3). Hence the three medians have no common point, and the conclusion of Proposition 21.2.7 is false here.

(c) The proof solved $\frac{3}{2}s = 1$ for s, which needs 3 to be invertible. Over $\mathbb{F}_3$ the point $\frac{1}{3}(P_1 + P_2 + P_3)$ does not exist, because $3 = 0$ has no inverse; the weights $(\frac{1}{3}, \frac{1}{3}, \frac{1}{3})$ cannot be written down at all. Concretely, the equation $1 - s = \frac{s}{2}$ becomes $1 - s = 2s$, that is, $1 = 3s = 0$, which has no solution: the parametrizations of m_1 and m_2 never agree. So the hypothesis $3 \neq 0$ is not an artifact of the proof; it is needed for the statement.

21.3 Convex Polyhedra, Geometrically

Chapter 17 built the theory of convex sets and proved its main theorems: that a compact convex set is the hull of its extreme points, that a bounded polyhedron and a polytope are the same thing, and that a feasible, bounded linear program and its dual have the same optimal value. **This section proves none of that again.** It reads those theorems as statements about the geometry of a solid with flat sides: what its faces are, how they fit together, and what a linear program looks like when the objective is a family of parallel hyperplanes sliding across it.

Everything here is a corollary of Chapter 17 or a short argument on top of it, and every citation points back there.

Throughout, the field is $\mathbb{R}$ and the space is $\mathbb{R}^n$ with the dot product, as in Chapter 17. A polyhedron is a set $P = \{\mathbf{x} \in \mathbb{R}^n : \mathbf{A}\mathbf{x} \le \mathbf{b}\}$ (Definition 17.9.2), with $\mathbf{A} \in M_{m\times n}(\mathbb{R})$ whose rows we write $\mathbf{a}_1^\top, \dots, \mathbf{a}_m^\top$, so that $\mathbf{A}\mathbf{x} \le \mathbf{b}$ is the list of inequalities $\mathbf{a}_i^\top \mathbf{x} \le b_i$. A **vertex** of P is an extreme point of it (Definition 17.8.1), and $\operatorname{ext} P$ is the set of them. We use Chapters 15 and 17's topological words — closed, bounded, compact — only inside the results we cite; nothing here develops them further.

21.3.1 Faces, cut by a supporting hyperplane

A cube has six square sides, twelve edges and eight corners, and each of them is the part of the cube touched by a plane that has the whole cube on one side. That is the picture to formalize. The tool is Chapter 17's supporting hyperplane (Theorem 17.3.6): a hyperplane through a point of a convex set with the set in one of its closed half-spaces.

A face of a polyhedron is the part of it touched by a hyperplane that does not cut into it.

Definition 21.3.1 — Face of a Polyhedron

Let $P \subseteq \mathbb{R}^n$ be a polyhedron. A **face** of P is a set of the form

$$F = \{\mathbf{x} \in P : \mathbf{c}^\top \mathbf{x} = \beta\}$$

for some $\mathbf{c} \in \mathbb{R}^n$ and $\beta \in \mathbb{R}$ such that $\mathbf{c}^\top \mathbf{x} \le \beta$ **for every** $\mathbf{x} \in P$. A face other than P itself is called **proper**.

Clause by clause. The pair $(\mathbf{c}, \beta)$ must be a **valid inequality** for P: the whole polyhedron lies in the closed half-space $\{\mathbf{c}^\top \mathbf{x} \le \beta\}$. The face is then what the boundary hyperplane $\{\mathbf{c}^\top \mathbf{x} = \beta\}$ actually touches. Note that $\mathbf{c}$ is allowed to be $\mathbf{0}$.

Two faces come free. Taking $\mathbf{c} = \mathbf{0}$ and $\beta = 0$ makes the inequality $0 \le 0$, valid everywhere, and $F = P$: **the whole polyhedron is a face of itself**. Taking $\mathbf{c} = \mathbf{0}$ and $\beta = 1$ makes the inequality $0 \le 1$, again valid, and $F = \emptyset$: **the empty set is a face**. These two are the degenerate cases, and they are kept because the theorems below are cleaner with them than without.

Chapter 17 §08 already has a notion of face for an arbitrary convex set, Definition 17.8.2: a convex subset $F \subseteq C$ that swallows every segment of C passing through it at an inner point. The two agree here in one direction at once.

> *Remark.* Every face in the sense of Definition 21.3.1 is a face in the sense of Definition 17.8.2. That is exactly Proposition 17.8.4 (a), applied with $\mathbf{w} = \mathbf{c}$ and $\alpha = \beta$, since on $\mathbb{R}^n$ the inner product $\langle \mathbf{c}, \mathbf{x} \rangle$ is $\mathbf{c}^\top \mathbf{x}$. So everything Chapter 17 proves about faces applies to ours; in particular Lemma 17.8.3 gives $\operatorname{ext} F = F \cap \operatorname{ext} P$. The converse — that every face of a **polyhedron** in Chapter 17's sense is cut out by a supporting hyperplane — is also true, and Exercise (C2: The two notions of face agree for a polyhedron) proves it. It uses flatness: the same exercise ends with a round convex set having a one-point face in the sense of Definition 17.8.2 that no supporting hyperplane isolates, so the converse fails for general convex sets.

Examples, in $\mathbb{R}^2$, with P the triangle $\{x_1 \geq 0,\ x_2 \geq 0,\ x_1 + x_2 \leq 3\}$ of Chapter 17 §09.

1. $\mathbf{c} = (1,1)$, $\beta = 3$. The inequality is valid by the third row, and the face is the slanted edge from $(3,0)$ to $(0,3)$.
2. $\mathbf{c} = (1,0)$, $\beta = 3$. Valid, since $x_1 \leq x_1 + x_2 \leq 3$ on P. The face is the single point $(3,0)$: the hyperplane $x_1 = 3$ touches the triangle at one corner.
3. $\mathbf{c} = (-1,0)$, $\beta = 0$. Valid by the first row, and the face is the vertical edge $\{0\} \times [0,3]$.
4. $\mathbf{c} = (1,1)$, $\beta = 4$. Valid, but never attained: the face is $\emptyset$.

A non-example by minimal change. In example 1 replace $\beta = 3$ by $\beta = 2$. The set $\{\mathbf{x} \in P : x_1 + x_2 = 2\}$ is still a segment inside P, still convex, and still a slice by a hyperplane. What fails is the one clause the definition insists on: $x_1 + x_2 \leq 2$ is **not** valid for P, since $(3,0) \in P$ violates it. The hyperplane cuts through the triangle instead of resting against it, and the slice is not a face. It also fails Definition 17.8.2: the segment from $(0,0)$ to $(3,0)$ passes through $(2,0)$ at an inner point but is not contained in the slice.

The reason faces are useful is that there are only finitely many of them, and each is again a polyhedron described by the **same** rows, some of them turned into equations.

Proposition 21.3.1 — Faces Are Polyhedra, and There Are Finitely Many

Let $P = \{\mathbf{x} \in \mathbb{R}^n : \mathbf{A}\mathbf{x} \leq \mathbf{b}\}$ with m rows. For $J \subseteq \{1, \dots, m\}$ put

$$P_J = \{\mathbf{x} \in P : \mathbf{a}_i^\top \mathbf{x} = b_i \text{ for every } i \in J\}.$$

Then:

(a) every P_J is a face of P, and it is a polyhedron;
(b) every **non-empty** face of P equals P_J for some J;
(c) consequently P has at most 2^m non-empty faces, and every face of P is a polyhedron.

Idea. For (a), add up the rows indexed by J: the sum $\sum_{i \in J} \mathbf{a}_i^\top \mathbf{x}$ is at most $\sum_{i \in J} b_i$ on P, and a sum of numbers each at most its bound hits the total bound only if every one of them does. So one valid inequality encodes all of J at once.

For (b), let F be a non-empty face and let J collect the rows that are tight at **every** point of F. Certainly $F \subseteq P_J$. For the other inclusion we need a point $\mathbf{x}^*$ of F at which every row outside J is **slack**; averaging finitely many points of F, one per slack row, produces it. Then, given $\mathbf{y} \in P_J$ with $\mathbf{c}^\top \mathbf{y} < \beta$, step from $\mathbf{x}^*$ **away** from $\mathbf{y}$. The rows in J are equations satisfied by both points, so they survive the step exactly; the rows outside J have room at $\mathbf{x}^*$, so they survive a short step. But the step raises $\mathbf{c}^\top \mathbf{x}$ above β, which no point of P may do.

Proof.

(a) Put $\mathbf{c} = \sum_{i \in J} \mathbf{a}_i$ and $\beta = \sum_{i \in J} b_i$, with the empty sums $\mathbf{0}$ and 0. For $\mathbf{x} \in P$,

$$\mathbf{c}^\top \mathbf{x} = \sum_{i \in J} \mathbf{a}_i^\top \mathbf{x} \leq \sum_{i \in J} b_i = \beta,$$

so the inequality is valid. If $\mathbf{x} \in P$ and $\mathbf{c}^\top \mathbf{x} = \beta$, then $\sum_{i \in J} (b_i - \mathbf{a}_i^\top \mathbf{x}) = 0$ is a sum of non-negative numbers, so each is zero and $\mathbf{x} \in P_J$; conversely every $\mathbf{x} \in P_J$ has $\mathbf{c}^\top \mathbf{x} = \beta$. Hence $P_J = \{\mathbf{x} \in P : \mathbf{c}^\top \mathbf{x} = \beta\}$ is a face. It is a polyhedron because each equation $\mathbf{a}_i^\top \mathbf{x} = b_i$ is the pair of inequalities $\mathbf{a}_i^\top \mathbf{x} \le b_i$ and $-\mathbf{a}_i^\top \mathbf{x} \le -b_i$, so P_J is cut out by $m + |J|$ inequalities.

(b) Let $F = \{\mathbf{x} \in P : \mathbf{c}^\top \mathbf{x} = \beta\}$ be non-empty, with $\mathbf{c}^\top \mathbf{x} \le \beta$ on P. Put

$$J = \{i : \mathbf{a}_i^\top \mathbf{x} = b_i \text{ for every } \mathbf{x} \in F\}.$$

Then $F \subseteq P_J$ by the definition of J, and it remains to prove $P_J \subseteq F$.
First note that F is convex: it is the intersection of the convex set P (Proposition 17.9.1) with the solution set of a linear equation, which is convex as the preimage of a point under $\mathbf{x} \mapsto \mathbf{c}^\top \mathbf{x}$ (Proposition 17.1.1 (b)); an intersection of convex sets is convex by Proposition 17.1.1 (a).
Step 1: a point of F with every row outside J slack. For each $i \notin J$ choose, by the definition of J, a point $\mathbf{x}_i \in F$ with $\mathbf{a}_i^\top \mathbf{x}_i < b_i$. If $J = \{1, \dots, m\}$ let $\mathbf{x}^*$ be any point of F. Otherwise let $k \ge 1$ be the number of indices outside J and let $\mathbf{x}^* = \frac{1}{k} \sum_{i \notin J} \mathbf{x}_i$, which lies in F by convexity. For each $i \notin J$, every term of $\mathbf{a}_i^\top \mathbf{x}^* = \frac{1}{k} \sum_{j \notin J} \mathbf{a}_i^\top \mathbf{x}_j$ is at most b_i and the term $j = i$ is strictly less, so $\mathbf{a}_i^\top \mathbf{x}^* < b_i$.
Step 2: the step away from $\mathbf{y}$. Let $\mathbf{y} \in P_J$ and suppose, for a contradiction, that $\mathbf{c}^\top \mathbf{y} < \beta$. For $t > 0$ put $\mathbf{z}_t = \mathbf{x}^* + t(\mathbf{x}^* - \mathbf{y})$. For $i \in J$ we have $\mathbf{a}_i^\top \mathbf{x}^* = b_i$, because $\mathbf{x}^* \in F \subseteq P_J$, and $\mathbf{a}_i^\top \mathbf{y} = b_i$, because $\mathbf{y} \in P_J$; hence

$$\mathbf{a}_i^\top \mathbf{z}_t = b_i + t(b_i - b_i) = b_i \le b_i.$$

For $i \notin J$ put $\delta = \min_{i \notin J} (b_i - \mathbf{a}_i^\top \mathbf{x}^*) > 0$ and $M = \max_{i \notin J} |\mathbf{a}_i^\top \mathbf{x}^* - \mathbf{a}_i^\top \mathbf{y}|$; both are minima and maxima of finitely many numbers. Choose $t > 0$ with $tM < \delta$, which is possible (any t will do if $M = 0$). Then for $i \notin J$,

$$\mathbf{a}_i^\top \mathbf{z}_t = \mathbf{a}_i^\top \mathbf{x}^* + t\big(\mathbf{a}_i^\top \mathbf{x}^* - \mathbf{a}_i^\top \mathbf{y}\big) \le \mathbf{a}_i^\top \mathbf{x}^* + tM < \mathbf{a}_i^\top \mathbf{x}^* + \delta \le b_i.$$

So $\mathbf{z}_t \in P$. But

$$\mathbf{c}^\top \mathbf{z}_t = \mathbf{c}^\top \mathbf{x}^* + t(\mathbf{c}^\top \mathbf{x}^* - \mathbf{c}^\top \mathbf{y}) = \beta + t(\beta - \mathbf{c}^\top \mathbf{y}) > \beta,$$

since $t > 0$ and $\beta - \mathbf{c}^\top \mathbf{y} > 0$. This contradicts the validity of $\mathbf{c}^\top \mathbf{x} \le \beta$ on P. Hence $\mathbf{c}^\top \mathbf{y} = \beta$ and $\mathbf{y} \in F$, so $P_J \subseteq F$ and $F = P_J$.

(c) There are 2^m subsets J, so by (b) at most that many non-empty faces. Each of them is a polyhedron by (a), and the empty face is the polyhedron $\{\mathbf{x} : 0 \le -1\}$. This proves the proposition.

■

The map $J \mapsto P_J$ is onto the non-empty faces but is very far from injective: adding to J a row that is already tight everywhere on P_J changes nothing, and adding two incompatible rows gives $\emptyset$.

Warning. **A row of the system need not be a side of the solid.** In $P = \{\mathbf{x} \in \mathbb{R}^2 : x_1 \le 1,\ x_2 \le 1,\ x_1 + x_2 \le 3\}$ the third row is implied by the first two, since $x_1 + x_2 \le 2$ on P. It defines no face except the empty one: $P_{\{3\}} = \{\mathbf{x} \in P : x_1 + x_2 = 3\} = \emptyset$. So a polyhedron with m rows can have far fewer than m sides, and counting rows is not

counting geometry. Conversely, Definition 21.3.1 never mentions the rows at all, which is why Proposition 21.3.1 has to prove that the faces can be read off them.

21.3.2 Vertices, edges, facets

A non-empty face F is a non-empty convex set, so it has a dimension: $\dim F = \dim \operatorname{aff} F$, as in Chapter 17 §01, and $\operatorname{aff} F$ is the flat $\mathbf{p} + U$ of Proposition 17.1.4 — a flat in the sense of Definition 21.2.1. The graded vocabulary follows.

Definition 21.3.2 — Edge, Facet

Let $P \subseteq \mathbb{R}^n$ be a non-empty polyhedron. A face of P of dimension 1 is an **edge**; a face of dimension $\dim P - 1$ is a **facet**. A face of dimension 0 is a single point, and the next proposition shows that these are exactly the vertices.

Proposition 21.3.2 — Three Descriptions of a Corner

Let $P = \{\mathbf{x} \in \mathbb{R}^n : \mathbf{A}\mathbf{x} \le \mathbf{b}\}$ and $\mathbf{v} \in P$. The following are equivalent.

(a) $\mathbf{v}$ is a vertex of P, that is, an extreme point.
(b) $\{\mathbf{v}\}$ is a face of P.
(c) Among the rows active at $\mathbf{v}$ there are n linearly independent ones, that is, $\mathbf{v}$ is a basic feasible point.

Idea.

(a) and (c) are Theorem 17.9.2, already proved. A one-point face is an extreme point by Proposition 17.8.4 (b). For the remaining implication, take J to be the active set: if the active rows have rank n, the system $\mathbf{A}_J\mathbf{x} = \mathbf{b}_J$ has $\mathbf{v}$ as its only solution, so $P_J = \{\mathbf{v}\}$, and Proposition 21.3.1 makes that a face.

Proof.

(a) $\Leftrightarrow$ (c) is Theorem 17.9.2.

(b) $\Rightarrow$ (a). Write $\{\mathbf{v}\} = \{\mathbf{x} \in P : \mathbf{c}^{\top}\mathbf{x} = \beta\}$ with $\mathbf{c}^{\top}\mathbf{x} \le \beta$ on P. By Proposition 17.8.4 (b), applied with $\mathbf{w} = \mathbf{c}$ and $\alpha = \beta$, $\mathbf{v} \in \operatorname{ext} P$.

(c) $\Rightarrow$ (b). Let $I = I(\mathbf{v})$ be the active set and $\mathbf{A}_I$ the matrix of active rows, of rank n by hypothesis. Its null space is $\{\mathbf{0}\}$ by Theorem 2.5.7, so $\mathbf{A}_I\mathbf{x} = \mathbf{b}_I$ has at most one solution; since $\mathbf{v}$ is one, it is the only one. Hence

$$P_I = \{\mathbf{x} \in P : \mathbf{A}_I\mathbf{x} = \mathbf{b}_I\} = \{\mathbf{v}\},$$

and P_I is a face by Proposition 21.3.1 (a). This proves the equivalence. ∎

So a corner of a polyhedron can be recognized three ways: by convexity (it is not an average), by

geometry (a hyperplane touches P there and nowhere else), or by algebra (enough constraints are tight). The three are used interchangeably from here on.

Bounded polyhedra are the ones with enough corners to rebuild them. This is the bounded half of the Minkowski–Weyl theorem, and it is the sentence this whole section is arranged around.

Theorem 21.3.3 — A Bounded Polyhedron Is the Hull of Its Vertices

Let $P \subseteq \mathbb{R}^n$ be a bounded polyhedron. Then $\operatorname{ext} P$ is finite and

$$P = \operatorname{conv}(\operatorname{ext} P).$$

Conversely, every polytope is a bounded polyhedron.

Proof. If $P = \emptyset$, both sides are $\emptyset$ and $\operatorname{ext} P = \emptyset$. Otherwise P is closed and convex by Proposition 17.9.1, and bounded by hypothesis, so it is compact by Corollary 15.2.5. By Theorem 17.8.5, $P = \operatorname{conv}(\operatorname{ext} P)$, and $\operatorname{ext} P$ is finite by Corollary 17.9.3. The converse is Theorem 17.9.5 (a). ∎

The same theorem applied to a face is what makes an edge a segment between two corners — the statement that lets one speak of walking along the edges of a solid.

Proposition 21.3.4 — An Edge Joins Two Vertices

Let $P \subseteq \mathbb{R}^n$ be a bounded polyhedron and F an edge of P. Then $F = [\mathbf{v}, \mathbf{w}]$ for two distinct vertices $\mathbf{v}, \mathbf{w}$ of P.

Idea. An edge is itself a bounded polyhedron, so it is the hull of its own vertices; those are vertices of P because a face passes extremeness upwards. Being 1-dimensional, it sits on a line, and the hull of finitely many points of a line is the segment between the outermost two.

Proof. By Proposition 21.3.1, F is a polyhedron, and it is bounded because $F \subseteq P$. By Theorem 21.3.3, $F = \operatorname{conv}(\operatorname{ext} F)$ with $\operatorname{ext} F$ finite, and $F \neq \emptyset$ since it has a dimension. By the remark after Definition 21.3.1, F is a face of P in the sense of Definition 17.8.2, so Lemma 17.8.3 gives $\operatorname{ext} F = F \cap \operatorname{ext} P$: every vertex of F is a vertex of P.

Fix $\mathbf{p} \in F$. By Proposition 17.1.4, $\operatorname{aff} F = \mathbf{p} + U$ with $U = \operatorname{span}\{\mathbf{x} - \mathbf{p} : \mathbf{x} \in F\}$, and $\dim U = \dim F = 1$, so $U = \operatorname{span}(\mathbf{u})$ for some $\mathbf{u} \neq \mathbf{0}$. Every point of F lies in $\operatorname{aff} F$, hence is $\mathbf{p} + t\mathbf{u}$ for exactly one $t \in \mathbb{R}$, the map $t \mapsto \mathbf{p} + t\mathbf{u}$ being injective because $\mathbf{u} \neq \mathbf{0}$. Let $t_1 \leq \cdots \leq t_k$ be the parameters of the points of $\operatorname{ext} F$, a non-empty finite list. A convex combination $\sum_j s_j(\mathbf{p} + t_j\mathbf{u})$ equals $\mathbf{p} + (\sum_j s_j t_j)\mathbf{u}$, and $\sum_j s_j t_j$ lies in $[t_1, t_k]$; conversely each $t \in [t_1, t_k]$ is $(1-\lambda)t_1 + \lambda t_k$ for some $\lambda \in [0,1]$. Hence, writing $[\mathbf{v}, \mathbf{w}]$ for the segment of Chapter 17 §01,

$$F = \{\mathbf{p} + t\mathbf{u} : t_1 \leq t \leq t_k\} = [\mathbf{v}, \mathbf{w}], \qquad \mathbf{v} = \mathbf{p} + t_1\mathbf{u}, \quad \mathbf{w} = \mathbf{p} + t_k\mathbf{u}.$$

If $t_1 = t_k$ then F is a single point and $\dim F = 0$, contrary to hypothesis; so $\mathbf{v} \neq \mathbf{w}$, and

both are vertices of P. This proves the proposition.

■

21.3.3 Two face lattices, computed

Faces are ordered by inclusion, and the resulting picture — which face lies in which — is the **face lattice** of the polyhedron. It is the combinatorial skeleton of the solid. Here it is in full for the two standard examples.

Example. (The faces of a cube)

Let $B_\infty = [-1,1]^n$, described by the $2n$ rows $\mathbf{e}_i^\top \mathbf{x} \le 1$ and $-\mathbf{e}_i^\top \mathbf{x} \le 1$. Find all faces of B_∞ and their dimensions.

Solution. By Proposition 21.3.1 (b) every non-empty face is some P_J. A set J of rows says, for each coordinate i, either nothing, or $x_i = 1$, or $x_i = -1$, or both; the last makes $P_J = \emptyset$. So the non-empty faces are indexed by **sign vectors** $\mathbf{s} \in \{-1, 0, 1\}^n$:

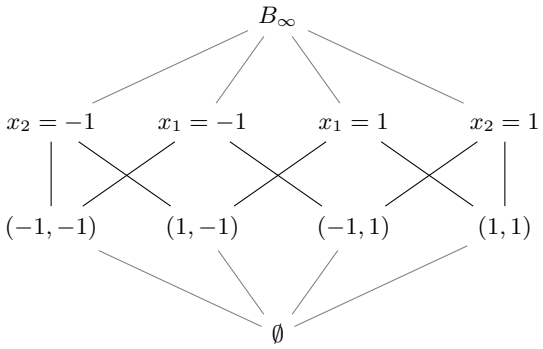
$$F_\mathbf{s} = \{\mathbf{x} \in B_\infty : x_i = s_i \text{ for every } i \text{ with } s_i \neq 0\}.$$

Each $F_\mathbf{s}$ is non-empty: the point with $x_i = s_i$ where $s_i \neq 0$ and $x_i = 0$ elsewhere lies in it. Distinct sign vectors give distinct faces, because $s_i = \pm 1$ exactly when the coordinate x_i is constantly ± 1 on $F_\mathbf{s}$. So B_∞ has exactly 3^n non-empty faces, one for each sign vector, together with $\emptyset$.

Let $Z = \{i : s_i = 0\}$ and $z = |Z|$. Then $\operatorname{aff} F_\mathbf{s}$ is the flat $\{\mathbf{x} : x_i = s_i \text{ for } i \notin Z\}$, a coset of $\operatorname{span}\{\mathbf{e}_i : i \in Z\}$: it contains $F_\mathbf{s}$, and conversely $F_\mathbf{s}$ contains the point $\mathbf{p}$ with $p_i = s_i$ for $i \notin Z$ and $p_i = 0$ for $i \in Z$, together with $\mathbf{p} + \mathbf{e}_i$ for every $i \in Z$, whose differences from $\mathbf{p}$ span $\operatorname{span}\{\mathbf{e}_i : i \in Z\}$. By Proposition 17.1.4, $\dim F_\mathbf{s} = z$.

So the faces of dimension k are the sign vectors with exactly k zeros, and there are $\binom{n}{k} 2^{n-k}$ of them. For $n = 3$: 8 vertices ($k = 0$), 12 edges ($k = 1$), 6 facets ($k = 2$) and the cube itself, and $8 + 12 + 6 + 1 = 27 = 3^3$. Every vertex is a sign vector ± 1 in each coordinate, matching what Example (The cube and the cross-polytope) found by the rank test.

Here is the resulting lattice for the square $B_\infty \subseteq \mathbb{R}^2$, with $\emptyset$ at the bottom and the square at the top, and a line drawn when the lower face is contained in the upper one.



The face lattice of the square: one empty face, four vertices, four edges, and the square itself. Nine non-empty faces, 3^2

Example. (The faces of a simplex)

Let $\Delta_n = \{\mathbf{t} \in \mathbb{R}^n : t_i \geq 0,\ \sum_i t_i = 1\}$ be the standard simplex (Definition 17.1.2), described by the n rows $-t_i \leq 0$ together with $\mathbf{1}^\top \mathbf{t} \leq 1$ and $-\mathbf{1}^\top \mathbf{t} \leq -1$. Find all faces of Δ_n.

Solution. The last two rows are tight at every point of Δ_n, so including them in J changes nothing. A face is therefore P_J for J determined by a set $S \subseteq \{1, \ldots, n\}$ of coordinates forced to zero:

$$F_S = \{\mathbf{t} \in \Delta_n : t_i = 0 \text{ for every } i \in S\}.$$

Write $T = \{1, \ldots, n\} \setminus S$. If $T = \emptyset$ the conditions $\mathbf{t} = \mathbf{0}$ and $\sum_i t_i = 1$ clash, so $F_S = \emptyset$. If $T \neq \emptyset$, then F_S consists of the vectors $\mathbf{t} \geq \mathbf{0}$ supported in T with $\sum_{i \in T} t_i = 1$, which by Theorem 17.1.3 is exactly $\operatorname{conv}\{\mathbf{e}_i : i \in T\}$, a copy of $\Delta_{|T|}$. Its dimension is $|T| - 1$, by the computation of $\dim \Delta_k$ after Proposition 17.1.4. Distinct non-empty T give distinct faces, since $\mathbf{e}_i \in F_S$ exactly for $i \in T$.

So the non-empty faces of Δ_n are indexed by the **non-empty subsets** $T \subseteq \{1, \ldots, n\}$, and there are $2^n - 1$ of them: n vertices, $\binom{n}{2}$ edges, and so on up to Δ_n itself. For $n = 4$, the tetrahedron $\Delta_4 \subseteq \mathbb{R}^4$ of dimension 3 has $4 + 6 + 4 + 1 = 15 = 2^4 - 1$ non-empty faces.

The contrast is the point. The cube's lattice is the set of sign vectors; that of the simplex is the set of non-empty subsets. A cube in dimension n has 2^n vertices and $2n$ facets; a simplex has n vertices and n facets. The cube's corners grow exponentially with n, those of the simplex only linearly.

Quick check. How many faces does a triangle in $\mathbb{R}^2$ have, counting the empty face and the triangle itself?

Solution. Eight: $\emptyset$, three vertices, three edges, and the triangle. Count directly from Proposition 21.3.1 (b), writing the triangle as the polyhedron cut out by its three sides: $P_\emptyset$ is the triangle, each single row gives one side, each pair of rows gives the corner where those two sides meet, and all three rows together give $\emptyset$. That is $1 + 3 + 3$ non-empty faces, plus $\emptyset$. The count matches Example (The faces of a simplex) with $n = 3$, whose $2^3 - 1 = 7$ non-empty faces are indexed by the non-empty subsets of the three corners.

21.3.4 A linear program, seen

Fix $\mathbf{c} \in \mathbb{R}^n$ with $\mathbf{c} \neq \mathbf{0}$. The level sets $\{\mathbf{x} : \mathbf{c}^\top \mathbf{x} = \gamma\}$ of the objective are parallel affine hyperplanes, one for each γ, and they sweep across $\mathbb{R}^n$ as γ grows, moving in the direction $\mathbf{c}$. Maximizing $\mathbf{c}^\top \mathbf{x}$ over a polyhedron P means pushing the sweeping hyperplane as far as it will go while still touching P. Two things can happen: it escapes to infinity, and the program is unbounded; or there is a last hyperplane that touches, and what it touches is a face.

Proposition 21.3.5 — The Optimal Set Is a Face

Let $P \subseteq \mathbb{R}^n$ be a polyhedron, $\mathbf{c} \in \mathbb{R}^n$, and suppose $\mathbf{c}^\top \mathbf{x}$ attains a maximum $\gamma^\star$ on P. Then the set $F^\star$ of maximizers is a non-empty face of P. If P is bounded, $F^\star$ contains a vertex of P.

Proof. By the definition of a maximum, $\mathbf{c}^\top \mathbf{x} \leq \gamma^\star$ for every $\mathbf{x} \in P$, and $F^\star = \{\mathbf{x} \in P : \mathbf{c}^\top \mathbf{x} = \gamma^\star\}$ is non-empty. That is Definition 21.3.1 verbatim, so $F^\star$ is a face.

Suppose P is bounded. Then $F^\star \subseteq P$ is a bounded polyhedron by Proposition 21.3.1, and non-empty, so $\operatorname{ext} F^\star \neq \emptyset$ by Theorem 21.3.3 (a non-empty set is not the hull of the empty set). By the remark after Definition 21.3.1 and Lemma 17.8.3, $\operatorname{ext} F^\star = F^\star \cap \operatorname{ext} P$, so any point of $\operatorname{ext} F^\star$ is a vertex of P lying in $F^\star$.

■

The last sentence is Corollary 17.8.6 read geometrically, and it says a little more than that corollary: not only is *some* maximizer a vertex, but the *whole* set of maximizers is a face — a single vertex when the optimum is unique, and otherwise an edge or a larger face, up to all of P when $\mathbf{c} = \mathbf{0}$. A linear program with a non-unique optimum has a positive-dimensional optimal face, and every point of it is optimal.

An algorithm now suggests itself: start at a vertex, and as long as some edge leaving it increases the objective, walk along that edge to the vertex at its other end (Proposition 21.3.4 guarantees there is one, when P is bounded). That is the idea of the **simplex method**, sketched in Chapter 17 §09 after Corollary 17.9.3. **No algorithm is developed here or anywhere in this book:** Chapter 23 is where this book's algorithms live, and it treats the numerical linear algebra of elimination, least squares and eigenvalues, not linear programming. What this section supplies is the geometry an algorithm would exploit.

Example. (A linear program and its picture)

Maximize $3x_1 + 2x_2$ over

$$P = \{\mathbf{x} \in \mathbb{R}^2 : x_1 \geq 0,\ x_2 \geq 0,\ x_1 + x_2 \leq 5,\ 2x_1 + x_2 \leq 8\}.$$

Find the vertices, the optimum, the optimal face, and the dual optimal solution.

Solution. Number the rows (1) $-x_1 \leq 0$, (2) $-x_2 \leq 0$, (3) $x_1 + x_2 \leq 5$, (4) $2x_1 + x_2 \leq 8$. No two rows are multiples of each other, so each of the $\binom{4}{2} = 6$ pairs gives one basic

point, which we test against the other two rows:

pair	basic point	verdict
(1), (2)	$(0,0)$	feasible
(1), (3)	$(0,5)$	(4): $5 \le 8$: feasible
(1), (4)	$(0,8)$	(3): $8 \le 5$ fails
(2), (3)	$(5,0)$	(4): $10 \le 8$ fails
(2), (4)	$(4,0)$	(3): $4 \le 5$: feasible
(3), (4)	$(3,2)$	feasible

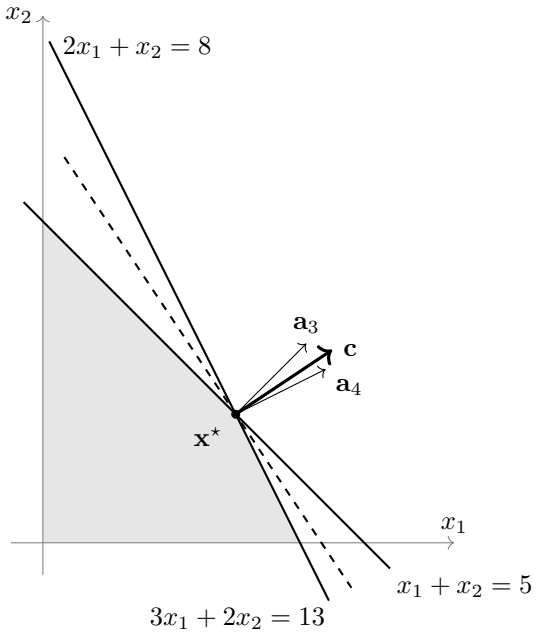
For the last pair, subtracting (3) from (4) gives $x_1 = 3$, hence $x_2 = 2$. By Proposition 21.3.2 the vertices are $(0,0)$, $(0,5)$, $(4,0)$ and $(3,2)$. P is bounded, since $0 \le x_1, x_2 \le 5$ on it, so by Theorem 21.3.3 it is the quadrilateral $\operatorname{conv}\{(0,0),(4,0),(3,2),(0,5)\}$.

The objective takes the value 0 at $(0,0)$, 10 at $(0,5)$, 12 at $(4,0)$ and 13 at $(3,2)$, so by Proposition 21.3.5 the maximum is 13, at $\mathbf{x}^\star = (3,2)$, and the optimal face is $\{\mathbf{x} \in P : 3x_1 + 2x_2 = 13\}$. Since only one vertex achieves 13 and the face is the hull of its vertices, the optimal face is the single point $\{(3,2)\}$: the optimum is unique.

The rows active at $\mathbf{x}^\star$ are (3) and (4), with outer normals $\mathbf{a}_3 = (1,1)$ and $\mathbf{a}_4 = (2,1)$. And

$$\mathbf{c} = (3,2) = 1 \cdot (1,1) + 1 \cdot (2,1) = 1 \cdot \mathbf{a}_3 + 1 \cdot \mathbf{a}_4,$$

so $\mathbf{y} = (1,1)$ is a candidate for the dual. In the notation of Definition 17.6.2, with $\mathbf{A}$ the rows $(1,1)$ and $(2,1)$ and $\mathbf{b} = (5,8)$, the dual asks to minimize $5y_1 + 8y_2$ subject to $y_1 + 2y_2 \ge 3$, $y_1 + y_2 \ge 2$, $\mathbf{y} \ge \mathbf{0}$. At $\mathbf{y} = (1,1)$ both constraints are equalities and the value is $5 + 8 = 13$, which matches. By Corollary 17.6.2 (a), $\mathbf{x}^\star$ and $\mathbf{y}$ are both optimal, and no further checking is needed.



The feasible quadrilateral, the level line of the objective through the optimum, and the two active outer normals whose non-negative combination is $\mathbf{c} = \mathbf{a}_3 + \mathbf{a}_4$

21.3.5 What the dual variables are, geometrically

The example ended with an identity worth isolating: the objective vector was a **non-negative** combination of the outer normals of the constraints active at the optimum, and the coefficients were the dual optimal solution. That is the geometric content of duality, and Chapter 17 has already done all the work.

Recall Chapter 17 §06's pair of programs, with $\mathbf{A} \in M_{m\times n}(\mathbb{R})$, $\mathbf{b} \in \mathbb{R}^m$, $\mathbf{c} \in \mathbb{R}^n$:

$$\begin{aligned} &\text{(P)} \quad \text{maximize } \mathbf{c}^\top \mathbf{x} \ \text{ subject to } \mathbf{A}\mathbf{x} \le \mathbf{b},\ \mathbf{x} \ge \mathbf{0};\\ &\text{(D)} \quad \text{minimize } \mathbf{b}^\top \mathbf{y} \ \text{ subject to } \mathbf{A}^\top \mathbf{y} \ge \mathbf{c},\ \mathbf{y} \ge \mathbf{0}. \end{aligned}$$

The feasible region of (P) is the polyhedron with the m rows $\mathbf{a}_i^\top \mathbf{x} \le b_i$ and the n rows $(-\mathbf{e}_j)^\top \mathbf{x} \le 0$. The **outer normal** of a row is the vector on its left-hand side: $\mathbf{a}_i$ for the i-th constraint and $-\mathbf{e}_j$ for the sign constraint on x_j.

Proposition 21.3.6 — Dual Variables Are the Weights of the Active Normals

Let $\mathbf{x}^\star$ be an optimal solution of (P). Then there are $\mathbf{y} \in \mathbb{R}^m$ and $\mathbf{s} \in \mathbb{R}^n$ with $\mathbf{y} \ge \mathbf{0}$ and $\mathbf{s} \ge \mathbf{0}$ such that

$$\mathbf{c} = \sum_{i=1}^{m} y_i \mathbf{a}_i + \sum_{j=1}^{n} s_j (-\mathbf{e}_j),$$

where $y_i = 0$ whenever $\mathbf{a}_i^\top \mathbf{x}^\star < b_i$, and $s_j = 0$ whenever $x_j^\star > 0$. That is, $\mathbf{c}$ is a non-negative combination of the outer normals of the constraints **active at** $\mathbf{x}^\star$, and the weights are an optimal solution of (D).

Idea. Strong duality hands over an optimal $\mathbf{y}$ for (D); the slack $\mathbf{s} = \mathbf{A}^\top \mathbf{y} - \mathbf{c}$ is non-negative because $\mathbf{y}$ is dual feasible, and rearranging is the displayed identity. Complementary slackness is exactly the statement that the weights vanish on the inactive constraints.

Proof. Since $\mathbf{x}^\star$ is feasible, (P) is feasible, and $\mathbf{c}^\top \mathbf{x} \le \mathbf{c}^\top \mathbf{x}^\star$ for every feasible $\mathbf{x}$, so (P) is not unbounded. By Theorem 17.6.3 (b), (D) is therefore feasible, and by Theorem 17.6.3 (a) both programs have optimal solutions with equal optimal values; let $\mathbf{y}$ be an optimal solution of (D). Then $\mathbf{y} \ge \mathbf{0}$ and $\mathbf{A}^\top \mathbf{y} \ge \mathbf{c}$, so $\mathbf{s} := \mathbf{A}^\top \mathbf{y} - \mathbf{c} \ge \mathbf{0}$. Reading the j-th coordinate of $\mathbf{A}^\top \mathbf{y}$ as $\sum_i y_i a_{ij}$, we get $\mathbf{A}^\top \mathbf{y} = \sum_i y_i \mathbf{a}_i$, and hence

$$\mathbf{c} = \mathbf{A}^\top \mathbf{y} - \mathbf{s} = \sum_{i=1}^{m} y_i \mathbf{a}_i + \sum_{j=1}^{n} s_j (-\mathbf{e}_j).$$

Both $\mathbf{x}^\star$ and $\mathbf{y}$ are optimal, so Theorem 17.6.5 applies: its condition (i) says $y_i > 0$ forces $(\mathbf{A}\mathbf{x}^\star)_i = b_i$, which is the contrapositive of "$\mathbf{a}_i^\top \mathbf{x}^\star < b_i$ forces $y_i = 0$"; its condition (ii) says $x_j^\star > 0$ forces $(\mathbf{A}^\top \mathbf{y})_j = c_j$, that is $s_j = 0$. This proves the proposition. ∎

So a dual optimal solution is a **certificate written in normals**. The hyperplane $\{\mathbf{x} : \mathbf{c}^\top \mathbf{x} = \mathbf{b}^\top \mathbf{y}\}$ supports the feasible region at $\mathbf{x}^\star$, by Theorem 17.6.1 and equality of the optimal values,

and Proposition 21.3.6 says how its normal $\mathbf{c}$ is assembled from the normals of the facets meeting at $\mathbf{x}^\star$. Increasing b_i loosens the i-th constraint, and y_i **bounds** the gain: the dual feasible region $\{\mathbf{y} \geq \mathbf{0} : \mathbf{A}^\top \mathbf{y} \geq \mathbf{c}\}$ does not mention $\mathbf{b}$ at all, so $\mathbf{y}$ stays dual feasible when b_i is raised to $b_i + \varepsilon$, and Theorem 17.6.1 then caps the objective of every point feasible for the loosened program at $\mathbf{b}^\top \mathbf{y} + \varepsilon y_i$, the old optimal value plus εy_i. That y_i is also the **exact** rate of gain, its *shadow price* in the economists' phrase, says more, and this book does not prove it; nothing here uses it, and it can fail. Take $n = 1$, $m = 2$, $\mathbf{A} = \left(\begin{smallmatrix} 1 \\ 1 \end{smallmatrix}\right)$, $\mathbf{b} = (1, 1)$ and $\mathbf{c} = 1$, so that (P) maximizes x subject to $x \leq 1$ written twice and $x \geq 0$. Its optimum is 1, and $\mathbf{y} = (1, 0)$ is dual feasible with $\mathbf{b}^\top \mathbf{y} = 1$, hence dual optimal by Corollary 17.6.2 (a); but raising b_1 leaves the second copy binding and the optimum at 1, a gain of 0 against $y_1 = 1$. The same pair shows which half of complementary slackness is available: Theorem 17.6.5 (i) says $y_i > 0$ forces row i tight, so a constraint **slack** at the optimum has $y_i = 0$, and that is what Proposition 21.3.6 records. The converse is the trap — here $y_2 = 0$ while row 2 is tight.

21.3.6 Polyhedra without corners

Boundedness is doing real work in Theorem 21.3.3, and the failures are worth seeing.

Example. (A slab, and a quadrant)

(a) Find the faces of the slab $S = \{\mathbf{x} \in \mathbb{R}^3 : 0 \leq x_3 \leq 1\}$, and its vertices.

(b) Show that $\max\{x_1 + x_2 : \mathbf{x} \in Q\}$ does not exist for the quadrant $Q = \{\mathbf{x} \in \mathbb{R}^2 : x_1 \geq 0,\ x_2 \geq 0\}$, although Q has a vertex.

Solution.

(a) S has the two rows $-x_3 \leq 0$ and $x_3 \leq 1$. By Proposition 21.3.1 the non-empty faces are among $P_\emptyset = S$, $P_{\{1\}} = \{x_3 = 0\}$, $P_{\{2\}} = \{x_3 = 1\}$ and $P_{\{1,2\}} = \emptyset$. So there are three non-empty faces: S and two parallel planes, of dimensions 3, 2, 2. There is no face of dimension 0 or 1. In particular S has **no vertices**: at any $\mathbf{x} \in S$ the active rows are among $\pm\mathbf{e}_3$, of rank at most $1 < 3$, so Theorem 17.9.2 denies a vertex. Hence $\operatorname{conv}(\operatorname{ext} S) = \operatorname{conv} \emptyset = \emptyset \neq S$, and Theorem 17.8.5 indeed needs compactness. Note also that $\max\{-x_3 : \mathbf{x} \in S\} = 0$ **is** attained, on the whole face $\{x_3 = 0\}$, which contains no vertex: the last sentence of Proposition 21.3.5 needs boundedness too.

(b) The point $(0, 0)$ is a vertex of Q: the two active rows $-\mathbf{e}_1, -\mathbf{e}_2$ are independent, so Theorem 17.9.2 applies. It is the only one, since at any other point of Q at most one row is active. But $(t, t) \in Q$ for every $t \geq 0$ and $x_1 + x_2 = 2t$ there, so the objective is unbounded above and no maximum exists. A polyhedron can have corners and still have no optimum.

Warning. **"Vertex" and "corner of the picture" can both be empty words for an unbounded polyhedron.** The slab above is a perfectly ordinary convex solid, closed, with a genuine boundary, and it has no vertices, no edges, and no bounded face. Nothing in this section rebuilds it from finitely many points, and nothing should: by Theorem 17.9.5 (a) a polyhedron is a polytope exactly when it is bounded. The general finite description of an unbounded polyhedron needs directions as well as points — every non-empty polyhedron is a polytope plus a finitely generated cone — which Chapter 17 derives from Theorem 17.9.5 (b) in Exercise (C1: Unbounded polyhedra), and which is

not pursued here.

21.3.7.1 A. Check your understanding

Exercise A1.

(a) State Definition 21.3.1, and say which pair $(\mathbf{c}, \beta)$ exhibits P itself as a face and which exhibits $\emptyset$.

(b) True or false: a polyhedron given by m inequalities in $\mathbb{R}^n$ has exactly 2^m non-empty faces. Justify your answer.

(c) Give the three equivalent descriptions of a vertex from Proposition 21.3.2.

(d) True or false: if a linear program over a bounded non-empty polyhedron has two distinct optimal solutions, it has infinitely many. Justify your answer.

(e) How many faces of dimension 2 does the cube $[-1, 1]^4$ have?

Solution.

(a) A face of a polyhedron P is a set $\{\mathbf{x} \in P : \mathbf{c}^\top \mathbf{x} = \beta\}$ for some $\mathbf{c}, \beta$ with $\mathbf{c}^\top \mathbf{x} \le \beta$ valid on all of P. The pair $(\mathbf{0}, 0)$ gives $F = P$; the pair $(\mathbf{0}, 1)$ gives $F = \emptyset$.

(b) False; 2^m is only an upper bound (Proposition 21.3.1 (c)). The map $J \mapsto P_J$ need not be injective, and some P_J may be empty. The warning after that proposition has $m = 3$ rows in $\mathbb{R}^2$ and only four non-empty faces: the polyhedron, two edges and one vertex.

(c) $\mathbf{v} \in P$ is a vertex when: it is an extreme point of P; or $\{\mathbf{v}\}$ is a face of P; or among the rows active at $\mathbf{v}$ there are n linearly independent ones.

(d) True. The optimal set is a face (Proposition 21.3.5), hence convex, so it contains the whole segment joining the two optimal points, and a segment with distinct ends has infinitely many points.

(e) By Example (The faces of a cube) with $n = 4$, $k = 2$: $\binom{4}{2} 2^{4-2} = 6 \cdot 4 = 24$.

21.3.7.2 B. Practice

Exercise B1: Vertices and faces of a region.

Let

$$P = \{\mathbf{x} \in \mathbb{R}^2 : x_1 \ge 0,\ x_2 \ge 0,\ x_1 + 2x_2 \le 8,\ 2x_1 + x_2 \le 10\}.$$

Find all vertices of P, list all of its faces, and maximize $x_1 + 3x_2$ over P.

Solution. Number the rows (1) $-x_1 \le 0$, (2) $-x_2 \le 0$, (3) $x_1 + 2x_2 \le 8$, (4) $2x_1 + x_2 \le 10$.

No two are multiples, so each of the six pairs gives a basic point:

pair	point	verdict
(1), (2)	$(0,0)$	feasible
(1), (3)	$(0,4)$	(4): $4 \le 10$: feasible
(1), (4)	$(0,10)$	(3): $20 \le 8$ fails
(2), (3)	$(8,0)$	(4): $16 \le 10$ fails
(2), (4)	$(5,0)$	(3): $5 \le 8$: feasible
(3), (4)	$(4,2)$	feasible

For the last pair, twice (3) minus (4) gives $3x_2 = 6$, so $x_2 = 2$ and $x_1 = 8 - 4 = 4$. By Proposition 21.3.2 the vertices are $(0,0)$, $(0,4)$, $(5,0)$ and $(4,2)$, so P is a quadrilateral, not a pentagon; two of the six basic points are infeasible. P is bounded ($0 \le x_1 \le 5$, $0 \le x_2 \le 4$ on it), so $P = \operatorname{conv}\{(0,0),(5,0),(4,2),(0,4)\}$ by Theorem 21.3.3.

By Proposition 21.3.1 (b) every non-empty face is some P_J. The four singletons give the four edges, computed directly: $P_{\{1\}} = \{x_1 = 0,\ 0 \le x_2 \le 4\}$; $P_{\{2\}} = \{x_2 = 0,\ 0 \le x_1 \le 5\}$; $P_{\{3\}} = \{x_1 + 2x_2 = 8\} \cap P$, where $x_1 = 8 - 2x_2 \ge 0$ gives $x_2 \le 4$ and $2x_1 + x_2 = 16 - 3x_2 \le 10$ gives $x_2 \ge 2$, a segment from $(4,2)$ to $(0,4)$; and $P_{\{4\}} = \{2x_1 + x_2 = 10\} \cap P$, which in the same way is the segment from $(4,2)$ to $(5,0)$. The six pairs give $P_{\{1,2\}} = \{(0,0)\}$, $P_{\{1,3\}} = \{(0,4)\}$, $P_{\{2,4\}} = \{(5,0)\}$, $P_{\{3,4\}} = \{(4,2)\}$, and $P_{\{1,4\}} = P_{\{2,3\}} = \emptyset$, the two infeasible basic points; every J with three or more rows gives $\emptyset$, since no point of P has three rows active. So P has ten faces in all: $\emptyset$, four vertices, four edges and P itself.

The objective $x_1 + 3x_2$ takes the values 0, 5, 10, 12 at $(0,0)$, $(5,0)$, $(4,2)$, $(0,4)$. By Proposition 21.3.5 the maximum is 12, attained at $(0,4)$ alone.

Exercise B2: Reading the dual off the normals.

For the program of Exercise (B1: Vertices and faces of a region) with objective $x_1 + 3x_2$, use Proposition 21.3.6 to write $\mathbf{c} = (1,3)$ as a non-negative combination of the outer normals of the constraints active at the optimum, and check the resulting dual solution against Corollary 17.6.2.

Solution. The optimum is $\mathbf{x}^\star = (0,4)$. The active rows there are (1), with outer normal $-\mathbf{e}_1 = (-1,0)$, and (3), with outer normal $\mathbf{a}_3 = (1,2)$. In the notation of Definition 17.6.2 the rows of $\mathbf{A}$ are (3) and (4) in that order, so the weight on $\mathbf{a}_3$ is y_1. Writing $\mathbf{c} = y_1\mathbf{a}_3 + s_1(-\mathbf{e}_1)$ with $\mathbf{a}_3 = (1,2)$:

$$(1,3) = y_1(1,2) + s_1(-1,0)$$

gives $2y_1 = 3$, so $y_1 = \frac{3}{2}$, and $1 = \frac{3}{2} - s_1$, so $s_1 = \frac{1}{2}$. Both are non-negative, as Proposition 21.3.6 requires. Row (4) is inactive at $\mathbf{x}^\star$, so its weight is $y_2 = 0$; and $x_2^\star = 4 > 0$, so the slack on the second sign constraint is $s_2 = 0$.

So $\mathbf{A}$ has rows $(1,2)$ and $(2,1)$, with $\mathbf{b} = (8,10)$ and $\mathbf{c} = (1,3)$. The dual solution read off is $\mathbf{y} = (\frac{3}{2}, 0)$, which satisfies $\mathbf{y} \ge \mathbf{0}$ and

$$\mathbf{A}^\top \mathbf{y} = \tfrac{3}{2}(1,2) = \left(\tfrac{3}{2}, 3\right) \ge (1,3) = \mathbf{c},$$

so it is dual feasible, with value $\mathbf{b}^\top \mathbf{y} = 8 \cdot \frac{3}{2} = 12$. Since the primal value at $(0, 4)$ is also 12, Corollary 17.6.2 (a) confirms that both are optimal.

Exercise B3: Faces of the cross-polytope.

Let $B_1 = \{\mathbf{x} \in \mathbb{R}^n : \mathbf{s}^\top \mathbf{x} \le 1 \text{ for every sign vector } \mathbf{s} \in \{-1, 1\}^n\}$, the cross-polytope of Example (The cube and the cross-polytope). Determine the face P_J for J a single sign vector $\mathbf{s}$, and its dimension. How many facets does B_1 have?

Solution. For a single sign vector $\mathbf{s}$, $P_{\{\mathbf{s}\}} = \{\mathbf{x} \in B_1 : \mathbf{s}^\top \mathbf{x} = 1\}$. Now $\mathbf{s}^\top \mathbf{x} = \sum_i s_i x_i \le \sum_i |x_i| = \|\mathbf{x}\|_1$, term by term, so equality holds exactly when $s_i x_i = |x_i|$ for every i; and $\|\mathbf{x}\|_1 = \max_{\mathbf{s}} \mathbf{s}^\top \mathbf{x} \le 1$ on B_1, as Example (The cube and the cross-polytope) records. So $\mathbf{s}^\top \mathbf{x} = 1$ forces $\|\mathbf{x}\|_1 = 1$ and $s_i x_i = |x_i| \ge 0$ for every i; conversely those conditions give $\mathbf{s}^\top \mathbf{x} = \|\mathbf{x}\|_1 = 1$. Writing $\mathbf{x} = \sum_i x_i \mathbf{e}_i$ with $x_i = s_i |x_i|$, we get

$$P_{\{\mathbf{s}\}} = \Big\{ \sum_i t_i (s_i \mathbf{e}_i) : t_i \ge 0,\ \sum_i t_i = 1 \Big\} = \operatorname{conv}\{s_1 \mathbf{e}_1, \dots, s_n \mathbf{e}_n\},$$

using Theorem 17.1.3. This is a copy of Δ_n, of dimension $n-1$ by the computation after Proposition 17.1.4. Since $\dim B_1 = n$ — it contains $\mathbf{0}$ and every $\pm\mathbf{e}_i$, and the differences $\mathbf{e}_i - \mathbf{0}$ span $\mathbb{R}^n$, so Proposition 17.1.4 gives $\operatorname{aff} B_1 = \mathbb{R}^n$ — each $P_{\{\mathbf{s}\}}$ is a facet. Distinct $\mathbf{s}$ give distinct facets, since $\mathbf{s}$ is recovered from $P_{\{\mathbf{s}\}}$ by the signs of the vertices $s_i \mathbf{e}_i$.

There are no others. Every non-empty face is P_J for a set J of sign vectors, by Proposition 21.3.1 (b), and if $\mathbf{s} \ne \mathbf{s}'$ both lie in J then $P_J \subseteq P_{\{\mathbf{s}\}} \cap P_{\{\mathbf{s}'\}}$. A point of that intersection has $x_i = s_i |x_i| = s_i' |x_i|$, so $x_i = 0$ whenever $s_i \ne s_i'$; hence the intersection is $\operatorname{conv}\{s_i \mathbf{e}_i : s_i = s_i'\}$, of dimension at most $n-2$, since at least one index is missing. So B_1 has exactly 2^n facets: in $\mathbb{R}^n$ it has $2n$ vertices and 2^n facets, exactly the reverse of the cube.

21.3.7.3 C. Going deeper

Exercise C1: A face of a face.

Let P be a polyhedron and F a face of P.

(a) Prove that every face of F is a face of P.

(b) Deduce that the faces of P contained in a fixed face F are exactly the faces of F.

Hint: for (a), use Proposition 21.3.1 to write both F and the face of F in the form P_J.

Solution.

(a) We may assume the face G of F is non-empty, since $\emptyset$ is a face of P. Fix a system $\mathbf{A}\mathbf{x} \le \mathbf{b}$ with $P = \{\mathbf{x} : \mathbf{A}\mathbf{x} \le \mathbf{b}\}$ and rows $\mathbf{a}_i^\top \mathbf{x} \le b_i$, $i = 1, \dots, m$. By Proposition 21.3.1 (b), $F = P_J$ for some J. By part (a) of the same proposition, F is cut out by the m original rows together with the rows $-\mathbf{a}_i^\top \mathbf{x} \le -b_i$ for $i \in J$. By (b) applied to F with **this** system, $G = F_K$ for some set K of those rows; since the rows $-\mathbf{a}_i^\top \mathbf{x} \le -b_i$ with $i \in J$ are tight everywhere on F, including them in K

changes nothing, so we may take $K \subseteq \{1, \dots, m\}$. Then

$$G = \{\mathbf{x} \in F : \mathbf{a}_i^\top \mathbf{x} = b_i \text{ for } i \in K\} = \{\mathbf{x} \in P : \mathbf{a}_i^\top \mathbf{x} = b_i \text{ for } i \in J \cup K\} = P_{J \cup K},$$

which is a face of P by Proposition 21.3.1 (a).

(b) By (a), every face of F is a face of P, and it is contained in F. Conversely let G be a face of P with $G \subseteq F$, say $G = \{\mathbf{x} \in P : \mathbf{c}^\top \mathbf{x} = \beta\}$ with $\mathbf{c}^\top \mathbf{x} \le \beta$ on P. Then $\mathbf{c}^\top \mathbf{x} \le \beta$ holds in particular on $F \subseteq P$, and

$$\{\mathbf{x} \in F : \mathbf{c}^\top \mathbf{x} = \beta\} = \{\mathbf{x} \in P : \mathbf{c}^\top \mathbf{x} = \beta\} \cap F = G \cap F = G,$$

so G is a face of F.

Exercise C2: The two notions of face agree for a polyhedron.

Let $P = \{\mathbf{x} \in \mathbb{R}^n : \mathbf{A}\mathbf{x} \le \mathbf{b}\}$ and let $F \subseteq P$ be a non-empty face in the sense of Definition 17.8.2: F is convex, and whenever $t\mathbf{y} + (1-t)\mathbf{z} \in F$ with $\mathbf{y}, \mathbf{z} \in P$ and $0 < t < 1$, both $\mathbf{y}$ and $\mathbf{z}$ lie in F.

(a) Let $J = \{i : \mathbf{a}_i^\top \mathbf{x} = b_i \text{ for every } \mathbf{x} \in F\}$. Prove that $F = P_J$.

(b) Deduce that F is a face in the sense of Definition 21.3.1, so the two notions agree for polyhedra.

Hint: for (a), Step 1 of the proof of Proposition 21.3.1 produces a point of F at which every row outside J is slack; use it as the midpoint of a short segment.

Solution.

(a) $F \subseteq P_J$ by the definition of J. For the reverse inclusion, note first that F is convex, so Step 1 of the proof of Proposition 21.3.1 applies verbatim and yields $\mathbf{x}^* \in F$ with $\mathbf{a}_i^\top \mathbf{x}^* < b_i$ for every $i \notin J$.
Let $\mathbf{y} \in P_J$. If $\mathbf{y} = \mathbf{x}^*$ we are done, so assume $\mathbf{y} \neq \mathbf{x}^*$ and put $\mathbf{z}_t = \mathbf{x}^* + t(\mathbf{x}^* - \mathbf{y})$ for $t > 0$. Exactly as in Step 2 of that proof, $\mathbf{a}_i^\top \mathbf{z}_t = b_i$ for $i \in J$ and, for small enough $t > 0$, $\mathbf{a}_i^\top \mathbf{z}_t < b_i$ for $i \notin J$; so $\mathbf{z}_t \in P$. Fix such a t. Then

$$\mathbf{x}^* = \frac{t}{1+t}\,\mathbf{y} + \frac{1}{1+t}\,\mathbf{z}_t,$$

a combination with positive coefficients adding to 1: indeed the right side is $\frac{t\mathbf{y} + \mathbf{x}^* + t\mathbf{x}^* - t\mathbf{y}}{1+t} = \mathbf{x}^*$. Both $\mathbf{y}$ and $\mathbf{z}_t$ lie in P and $\mathbf{x}^* \in F$, so the face property of Definition 17.8.2 forces $\mathbf{y} \in F$. Hence $P_J \subseteq F$ and $F = P_J$.

(b) By Proposition 21.3.1 (a), P_J is a face in the sense of Definition 21.3.1. Together with the remark after Definition 21.3.1, which gives the other direction for every face, the two notions coincide on polyhedra.

They do not coincide for general convex sets, and one round set shows it. Let $D = \{\mathbf{x} \in \mathbb{R}^2 : \|\mathbf{x}\| \le 1\}$, let $\mathbf{q} = (2, 0)$, let $C = \operatorname{conv}(D \cup \{\mathbf{q}\})$, and put $\mathbf{p} = \left(\frac{1}{2}, \frac{\sqrt{3}}{2}\right)$, so that $\|\mathbf{p}\| = 1$ and $\langle \mathbf{p}, \mathbf{q} \rangle = 1$. Since D is convex, Theorem 17.1.3 writes every point of C as $(1-s)\mathbf{d} + s\mathbf{q}$ with $\mathbf{d} \in D$ and $s \in [0, 1]$, whence

$$\langle \mathbf{p}, (1-s)\mathbf{d} + s\mathbf{q} \rangle = (1-s)\langle \mathbf{p}, \mathbf{d} \rangle + s \le (1-s)\|\mathbf{d}\| + s \le 1,$$

the first inequality by Theorem 10.1.5. Equality with $s < 1$ forces $\langle \mathbf{p}, \mathbf{d} \rangle = \|\mathbf{d}\| = 1$, hence $(\mathbf{p}, \mathbf{d})$ dependent and $\mathbf{d} = \mathbf{p}$; so $\{\mathbf{x} \in C : \langle \mathbf{p}, \mathbf{x} \rangle = 1\} = [\mathbf{p}, \mathbf{q}]$. Now $\{\mathbf{p}\}$ **is** a face of C in the sense of Definition 17.8.2: if $\mathbf{p} = t\mathbf{y} + (1-t)\mathbf{z}$ with $\mathbf{y}, \mathbf{z} \in C$ and $0 < t < 1$, then $1 = t\langle \mathbf{p}, \mathbf{y} \rangle + (1-t)\langle \mathbf{p}, \mathbf{z} \rangle$, and both inner products are at most 1, so both equal 1 and $\mathbf{y} = \mathbf{p} + a(\mathbf{q} - \mathbf{p})$, $\mathbf{z} = \mathbf{p} + b(\mathbf{q} - \mathbf{p})$ with $a, b \in [0, 1]$; then $ta + (1-t)b = 0$ forces $a = b = 0$. But no supporting hyperplane isolates $\mathbf{p}$. If $\langle \mathbf{c}, \mathbf{x} \rangle \le \beta$ on C with $\langle \mathbf{c}, \mathbf{p} \rangle = \beta$, then $\mathbf{c} \neq \mathbf{0}$, since $\mathbf{c} = \mathbf{0}$ gives the face C or $\emptyset$; testing the inequality at the point $\mathbf{c}/\|\mathbf{c}\|$ of D gives $\|\mathbf{c}\| \le \beta = \langle \mathbf{c}, \mathbf{p} \rangle \le \|\mathbf{c}\|$, so equality holds in Theorem 10.1.5 and $\mathbf{c} = \|\mathbf{c}\|\mathbf{p}$, $\beta = \|\mathbf{c}\|$. Then $\langle \mathbf{c}, \mathbf{q} \rangle = \|\mathbf{c}\|\langle \mathbf{p}, \mathbf{q} \rangle = \beta$, so $\mathbf{q}$ lies in the face too, and the face is not $\{\mathbf{p}\}$.

Exercise C3: The optimal face has no better vertex outside it.

Let $P \subseteq \mathbb{R}^n$ be a non-empty bounded polyhedron, $\mathbf{c} \in \mathbb{R}^n$, and let $F^\star$ be the optimal face of Proposition 21.3.5.

(a) Prove that $F^\star = \operatorname{conv}(F^\star \cap \operatorname{ext} P)$.

(b) Deduce that the optimal value of the program equals $\max\{\mathbf{c}^\top \mathbf{v} : \mathbf{v} \in \operatorname{ext} P\}$, a maximum over a finite set, and that this finite maximum is attained exactly at the vertices lying in $F^\star$.

Solution.

(a) $F^\star$ is a non-empty bounded polyhedron by Proposition 21.3.1, so Theorem 21.3.3 gives $F^\star = \operatorname{conv}(\operatorname{ext} F^\star)$. By the remark after Definition 21.3.1, $F^\star$ is a face of P in the sense of Definition 17.8.2, so Lemma 17.8.3 gives $\operatorname{ext} F^\star = F^\star \cap \operatorname{ext} P$. Substituting proves (a).

(b) By Corollary 17.9.3, $\operatorname{ext} P$ is finite, and it is non-empty by Theorem 21.3.3 since $P \neq \emptyset$. Write $\gamma^\star$ for the optimal value. Every vertex lies in P, so $\mathbf{c}^\top \mathbf{v} \le \gamma^\star$ for $\mathbf{v} \in \operatorname{ext} P$; and by (a) $F^\star$ contains a vertex, at which $\mathbf{c}^\top \mathbf{v} = \gamma^\star$. So the finite maximum equals $\gamma^\star$. A vertex $\mathbf{v}$ attains it exactly when $\mathbf{c}^\top \mathbf{v} = \gamma^\star$, which is exactly the condition $\mathbf{v} \in F^\star$ defining the optimal face.

21.4 Euclidean Motions

Affine geometry knows about lines, parallels and ratios along a line, but not about length. Put the standard inner product back on $\mathbb{R}^n$ and a new question appears: which maps of space leave every distance unchanged? One might expect a large and unruly collection, since the condition says nothing about linearity, nothing about continuity, and nothing about where the origin goes. The first theorem of this section says otherwise. A map that preserves distances is forced to be affine, with an orthogonal linear part — and it is forced without assuming that it is onto, which most treatments quietly do. The rest of the section turns that structure theorem into a complete list of the motions of the plane and of space.

Throughout, the field is $\mathbb{R}$, the space is $\mathbb{R}^n$ with the standard inner product, and the **distance** between $\mathbf{x}$ and $\mathbf{y}$ is $\|\mathbf{x} - \mathbf{y}\|$. Matrices are bold, points of $\mathbb{R}^n$ are bold vectors as usual, and we write $\mathbf{R}_\theta$ and the reflections of Theorem 10.7.5 for the elements of $\mathrm{O}(2)$.

21.4.1 Distance alone

Chapter 10 studied the **linear** maps preserving distance: the isometries, which in $\mathbb{R}^n$ are the orthogonal matrices (Theorem 10.7.3). But a translation $\mathbf{x} \mapsto \mathbf{x} + \mathbf{b}$ with $\mathbf{b} \neq \mathbf{0}$ also preserves every distance and is not linear, since it moves the origin. So the linear theory misses exactly what affine geometry was invented to supply, and the right notion drops linearity from the hypotheses altogether.

A Euclidean motion is a map of space that changes no distance.

Definition 21.4.1 — Euclidean Motion

A **Euclidean motion** of $\mathbb{R}^n$, or simply a **motion**, is a map $f\colon \mathbb{R}^n \to \mathbb{R}^n$ such that

$$\|f(\mathbf{x}) - f(\mathbf{y})\| = \|\mathbf{x} - \mathbf{y}\| \qquad \text{for all } \mathbf{x}, \mathbf{y} \in \mathbb{R}^n.$$

No linearity, continuity or surjectivity is assumed.

In words: the only requirement is that the distance between any two points equals the distance between their images. The quantifier is **for all** pairs, not for pairs at some special distance, and that turns out to be exactly the right amount of information.

Examples.

1. **Translations.** $t_{\mathbf{b}}(\mathbf{x}) = \mathbf{x} + \mathbf{b}$ satisfies $t_{\mathbf{b}}(\mathbf{x}) - t_{\mathbf{b}}(\mathbf{y}) = \mathbf{x} - \mathbf{y}$, so it is a motion for every $\mathbf{b}$. It is linear only when $\mathbf{b} = \mathbf{0}$.
2. **Orthogonal maps.** For $\mathbf{Q} \in \mathrm{O}(n)$, the map $\mathbf{x} \mapsto \mathbf{Q}\mathbf{x}$ is a motion: $\|\mathbf{Q}\mathbf{x} - \mathbf{Q}\mathbf{y}\| = \|\mathbf{Q}(\mathbf{x}-\mathbf{y})\| = \|\mathbf{x}-\mathbf{y}\|$, the last equality by Theorem 10.7.3 (a) applied to $T_{\mathbf{Q}}$, which is an isometry by part (f) of that theorem.
3. **Compositions.** If f and g are motions then so is $g \circ f$, since $\|g(f(\mathbf{x})) - g(f(\mathbf{y}))\| = \|f(\mathbf{x}) - f(\mathbf{y})\| = \|\mathbf{x} - \mathbf{y}\|$. In particular $\mathbf{x} \mapsto \mathbf{Q}\mathbf{x} + \mathbf{b}$ is a motion for every $\mathbf{Q} \in \mathrm{O}(n)$ and $\mathbf{b} \in \mathbb{R}^n$.
4. **The degenerate case** $n = 0$ is the one-point space and its only motion is the identity; for $n = 1$ the motions are $x \mapsto \pm x + b$, as the theorem below will confirm.

A non-example by minimal change. Take $f(\mathbf{x}) = 2\mathbf{x}$. It is linear, continuous and bijective, and it multiplies every distance by the same factor 2. The one clause of Definition 21.4.1 it fails is the only one there is: $\|f(\mathbf{x}) - f(\mathbf{y})\| = 2\|\mathbf{x} - \mathbf{y}\| \neq \|\mathbf{x} - \mathbf{y}\|$ as soon as $\mathbf{x} \neq \mathbf{y}$. A map that rescales all distances equally is a **similarity**, not a motion, and this book does not pursue them.

Why this definition, and why it is enough. Nothing in it mentions the vector space structure of $\mathbb{R}^n$; it is a statement about $\mathbb{R}^n$ as a set with a distance. The content of the next theorem is that the vector space structure is recoverable anyway. That is worth pausing on: distances alone remember which points are midpoints, hence which maps are affine, hence all of the linear algebra.

Theorem 21.4.1 — Every Motion Is Affine

Let $f\colon \mathbb{R}^n \to \mathbb{R}^n$ be a Euclidean motion. Then there are a unique $\mathbf{Q} \in \mathrm{O}(n)$ and a unique $\mathbf{b} \in \mathbb{R}^n$ with

$$f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b} \qquad \text{for every } \mathbf{x} \in \mathbb{R}^n.$$

In particular f is an affine map (Definition 21.1.3) whose linear part $\vec{f}$ (Theorem 21.1.5) is the isometry $T_{\mathbf{Q}}$.

Idea. Three steps. ① Move the origin out of the way: $g(\mathbf{x}) = f(\mathbf{x}) - f(\mathbf{0})$ is a motion fixing $\mathbf{0}$, so it preserves norms as well as distances. ② A map preserving both norms and distances preserves inner products, because the inner product is built from those two by polarization: $2\langle \mathbf{x}, \mathbf{y}\rangle = \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2 - \|\mathbf{x}-\mathbf{y}\|^2$. ③ A map preserving inner products is linear, and the way to see it is the reflex for showing a vector is zero: pair the vector $g(\mathbf{x}+\mathbf{y}) - g(\mathbf{x}) - g(\mathbf{y})$ with itself. Expanding the square turns it into a combination of inner products, each of which g has just been shown to preserve, and the combination is the square of $(\mathbf{x}+\mathbf{y}) - \mathbf{x} - \mathbf{y} = \mathbf{0}$.

Proof. **Step 1: reduce to a motion fixing the origin.** Put $\mathbf{b} = f(\mathbf{0})$ and $g(\mathbf{x}) = f(\mathbf{x}) - \mathbf{b}$. For all $\mathbf{x}, \mathbf{y}$,

$$\|g(\mathbf{x}) - g(\mathbf{y})\| = \|f(\mathbf{x}) - f(\mathbf{y})\| = \|\mathbf{x} - \mathbf{y}\|,$$

so g is a motion, and $g(\mathbf{0}) = \mathbf{0}$. Taking $\mathbf{y} = \mathbf{0}$ gives

$$\|g(\mathbf{x})\| = \|g(\mathbf{x}) - g(\mathbf{0})\| = \|\mathbf{x} - \mathbf{0}\| = \|\mathbf{x}\|$$

for every $\mathbf{x}$: g preserves norms.

Step 2: g preserves inner products. By Theorem 10.1.2 (c), for real vectors $\mathbf{u}, \mathbf{v}$,

$$\begin{aligned} \|\mathbf{u} - \mathbf{v}\|^2 &= \|\mathbf{u}\|^2 - 2\langle \mathbf{u}, \mathbf{v}\rangle + \|\mathbf{v}\|^2, \\ \text{so} \qquad 2\langle \mathbf{u}, \mathbf{v}\rangle &= \|\mathbf{u}\|^2 + \|\mathbf{v}\|^2 - \|\mathbf{u} - \mathbf{v}\|^2. \end{aligned}$$

This is the polarization identity of Lemma 10.7.2 in the form that uses the distance: the inner product is determined by norms and distances alone. Applying it to $g(\mathbf{x}), g(\mathbf{y})$ and then to $\mathbf{x}, \mathbf{y}$, and using Step 1 three times,

$$\begin{aligned} 2\langle g(\mathbf{x}), g(\mathbf{y})\rangle &= \|g(\mathbf{x})\|^2 + \|g(\mathbf{y})\|^2 - \|g(\mathbf{x}) - g(\mathbf{y})\|^2 \\ &= \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2 - \|\mathbf{x} - \mathbf{y}\|^2 = 2\langle \mathbf{x}, \mathbf{y}\rangle. \end{aligned}$$

So $\langle g(\mathbf{x}), g(\mathbf{y})\rangle = \langle \mathbf{x}, \mathbf{y}\rangle$ for all $\mathbf{x}, \mathbf{y}$.

Step 3: g is linear. Fix $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ and expand the squared norm of $\mathbf{d} = g(\mathbf{x}+\mathbf{y}) - g(\mathbf{x}) - g(\mathbf{y})$. For any three vectors $\mathbf{r}, \mathbf{s}, \mathbf{z}$, repeated use of Theorem 10.1.2 (c) gives

$$\begin{aligned} \|\mathbf{r} - \mathbf{s} - \mathbf{z}\|^2 = \|\mathbf{r}\|^2 + \|\mathbf{s}\|^2 + \|\mathbf{z}\|^2 \\ - 2\langle \mathbf{r}, \mathbf{s}\rangle - 2\langle \mathbf{r}, \mathbf{z}\rangle + 2\langle \mathbf{s}, \mathbf{z}\rangle. \end{aligned}$$

Apply this with $\mathbf{r} = g(\mathbf{x}+\mathbf{y})$, $\mathbf{s} = g(\mathbf{x})$, $\mathbf{z} = g(\mathbf{y})$. Every term on the right is a norm or an inner product of values of g, and Steps 1 and 2 replace each by the corresponding quantity for $\mathbf{x}+\mathbf{y}$, $\mathbf{x}$, $\mathbf{y}$. The result is the same expression with $\mathbf{r} = \mathbf{x}+\mathbf{y}$, $\mathbf{s} = \mathbf{x}$, $\mathbf{z} = \mathbf{y}$, that is, $\|(\mathbf{x}+\mathbf{y}) - \mathbf{x} - \mathbf{y}\|^2 = 0$. Hence $\|\mathbf{d}\|^2 = 0$ and $\mathbf{d} = \mathbf{0}$ by Theorem 10.1.2 (a), so

$$g(\mathbf{x}+\mathbf{y}) = g(\mathbf{x}) + g(\mathbf{y}).$$

For scalars, let $\lambda \in \mathbb{R}$ and expand in the same way:

$$\begin{aligned}\|g(\lambda\mathbf{x}) - \lambda g(\mathbf{x})\|^2 &= \|g(\lambda\mathbf{x})\|^2 - 2\lambda\langle g(\lambda\mathbf{x}), g(\mathbf{x})\rangle + \lambda^2\|g(\mathbf{x})\|^2 \\ &= \|\lambda\mathbf{x}\|^2 - 2\lambda\langle\lambda\mathbf{x}, \mathbf{x}\rangle + \lambda^2\|\mathbf{x}\|^2 \\ &= \lambda^2\|\mathbf{x}\|^2 - 2\lambda^2\|\mathbf{x}\|^2 + \lambda^2\|\mathbf{x}\|^2 = 0,\end{aligned}$$

so $g(\lambda\mathbf{x}) = \lambda g(\mathbf{x})$. Therefore g is linear.

Step 4: the matrix. Let $\mathbf{Q}$ be the matrix of g in the standard basis, so $g(\mathbf{x}) = \mathbf{Q}\mathbf{x}$. By Step 2, g preserves inner products, so $\mathbf{Q} \in \mathrm{O}(n)$ by Theorem 10.7.3 (b) and (f), the standard basis being orthonormal. Then $f(\mathbf{x}) = g(\mathbf{x}) + \mathbf{b} = \mathbf{Q}\mathbf{x} + \mathbf{b}$.

Uniqueness. If $\mathbf{Q}\mathbf{x} + \mathbf{b} = \mathbf{Q}'\mathbf{x} + \mathbf{b}'$ for every $\mathbf{x}$, then $\mathbf{x} = \mathbf{0}$ gives $\mathbf{b} = \mathbf{b}'$, and then $(\mathbf{Q} - \mathbf{Q}')\mathbf{x} = \mathbf{0}$ for every $\mathbf{x}$ gives $\mathbf{Q} = \mathbf{Q}'$. This proves the theorem.

■

Remark. **Surjectivity was never used.** The definition of a motion asks only that distances be preserved, and the proof never produces a preimage of anything. Most treatments define a motion to be a distance-preserving **bijection**, and then the bijectivity is an unused hypothesis — as the next corollary shows, it comes for free.

Corollary 21.4.2 — Motions Are Bijections

Every Euclidean motion f of $\mathbb{R}^n$ is a bijection, and f^{-1} is again a motion. The linear part of f^{-1} is $\mathbf{Q}^{\top}$, where $\mathbf{Q}$ is the linear part of f.

Proof. Write $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ by Theorem 21.4.1. Since $\mathbf{Q} \in \mathrm{O}(n)$, $\mathbf{Q}$ is invertible with $\mathbf{Q}^{-1} = \mathbf{Q}^{\top}$ (Theorem 10.7.3 (g1)), so the map $h(\mathbf{y}) = \mathbf{Q}^{\top}(\mathbf{y} - \mathbf{b}) = \mathbf{Q}^{\top}\mathbf{y} - \mathbf{Q}^{\top}\mathbf{b}$ satisfies $h(f(\mathbf{x})) = \mathbf{x}$ and $f(h(\mathbf{y})) = \mathbf{y}$. Hence f is a bijection with inverse h, which is a motion by examples 2 and 3 after Definition 21.4.1, with linear part $\mathbf{Q}^{\top}$.

■

Warning. **The Euclidean norm is doing real work.** Step 2 is the only place where the special shape of $\|\cdot\|$ is used, and for other norms the phenomenon fails. Here is a distance-preserving map that is not affine, for a norm of Chapter 15 and between spaces of different dimensions. Give $\mathbb{R}^2$ the norm $\|(y_1, y_2)\|_\infty = \max(|y_1|, |y_2|)$ of Chapter 15 and consider $\varphi\colon \mathbb{R} \to \mathbb{R}^2$, $\varphi(t) = (t, |t|)$. For $s, t \in \mathbb{R}$, Lemma 15.1.1 applied to the absolute value as a norm on $\mathbb{R}$ gives $\big||s| - |t|\big| \le |s - t|$, so

$$\|\varphi(s) - \varphi(t)\|_\infty = \max\big(|s - t|,\ \big||s| - |t|\big|\big) = |s - t|.$$

So φ preserves distances exactly, and it is visibly not affine: $\varphi(-1) = (-1, 1)$, $\varphi(0) = (0, 0)$ and $\varphi(1) = (1, 1)$, yet $\varphi(0)$ is not the midpoint of $\varphi(-1)$ and $\varphi(1)$, which is $(0, 1)$. Replacing $|t|$ by any function $\mathbb{R} \to \mathbb{R}$ that never changes by more than its input does gives another one. What makes Theorem 21.4.1 true is polarization, an identity special to the norms that come from an inner product, and not any property shared by all norms.

The determinant of the linear part now splits the motions into two halves, exactly as it splits

$\mathrm{O}(n)$.

Definition 21.4.2 — Direct and Opposite Motions

Let $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ be a motion of $\mathbb{R}^n$. It is **direct**, or orientation-preserving, if $\det \mathbf{Q} = 1$, and **opposite**, or orientation-reversing, if $\det \mathbf{Q} = -1$. These are the only possibilities: $\mathbf{Q}^{\top}\mathbf{Q} = \mathbf{I}_n$, and $\det \mathbf{Q}^{\top} = \det \mathbf{Q}$ (Theorem 6.4.5), so $(\det \mathbf{Q})^2 = \det(\mathbf{Q}^{\top}\mathbf{Q}) = 1$ by Theorem 6.5.4.

Quick check. For which n is the map $f(\mathbf{x}) = -\mathbf{x} + \mathbf{b}$ a direct motion of $\mathbb{R}^n$? Describe it for $n = 2$ and $n = 3$.

Solution. It is a motion with linear part $-\mathbf{I}_n$, and $\det(-\mathbf{I}_n) = (-1)^n$, so it is direct exactly when n is even. For $n = 2$ it is direct: $-\mathbf{I}_2 = \mathbf{R}_{\pi}$, and f is the half-turn about the point $\frac{1}{2}\mathbf{b}$, which is its unique fixed point, since $-\mathbf{x}+\mathbf{b} = \mathbf{x}$ forces $\mathbf{x} = \frac{1}{2}\mathbf{b}$. For $n = 3$ it is opposite: it is the point reflection $\mathbf{x} \mapsto 2(\frac{1}{2}\mathbf{b}) - \mathbf{x}$ in the point $\frac{1}{2}\mathbf{b}$, which sends each point to the point diametrically opposite it through that center.

21.4.2 The group of motions

Write $\mathrm{E}(n)$ for the set of Euclidean motions of $\mathbb{R}^n$ and $\mathrm{Trans}(n) = \{t_{\mathbf{b}} : \mathbf{b} \in \mathbb{R}^n\}$ for the translations. One proposition records how these fit together, and every part of it is a line of computation.

Proposition 21.4.3 — The Euclidean Group

(a) $\mathrm{E}(n)$ is a group under composition.

(b) The map $\lambda\colon \mathrm{E}(n) \to \mathrm{O}(n)$ sending a motion to its linear part is a surjective group homomorphism.

(c) $\ker \lambda = \mathrm{Trans}(n)$, and $\mathbf{b} \mapsto t_{\mathbf{b}}$ is a group isomorphism $(\mathbb{R}^n, +) \to \mathrm{Trans}(n)$.

(d) For every motion f with linear part $\mathbf{Q}$ and every $\mathbf{b} \in \mathbb{R}^n$,

$$f \circ t_{\mathbf{b}} \circ f^{-1} = t_{\mathbf{Q}\mathbf{b}}.$$

In particular a conjugate of a translation is a translation.

Idea. Write everything in the form $\mathbf{x} \mapsto \mathbf{Q}\mathbf{x} + \mathbf{b}$. Composing two such maps multiplies the matrices and moves the translation vectors through, so the matrix is exactly the part that composes without interference — which is what a homomorphism is. Part (d) is one substitution, and it explains where the translations sit: they are the motions that every other motion pushes around among themselves.

Proof. By Theorem 21.4.1 every motion is $\mathbf{x} \mapsto \mathbf{Q}\mathbf{x} + \mathbf{b}$ with $\mathbf{Q} \in \mathrm{O}(n)$, and conversely every such map is a motion (examples 2 and 3 after Definition 21.4.1). Write $f_{\mathbf{Q},\mathbf{b}}$ for it. A direct computation gives the composition rule:

$$f_{\mathbf{R},\mathbf{c}}\big(f_{\mathbf{Q},\mathbf{b}}(\mathbf{x})\big) = \mathbf{R}(\mathbf{Q}\mathbf{x} + \mathbf{b}) + \mathbf{c} = (\mathbf{R}\mathbf{Q})\mathbf{x} + (\mathbf{R}\mathbf{b} + \mathbf{c}),$$

so

$$f_{\mathbf{R},\mathbf{c}} \circ f_{\mathbf{Q},\mathbf{b}} = f_{\mathbf{RQ},\ \mathbf{Rb}+\mathbf{c}}. \tag{$*$}$$

(a) By Corollary 21.4.2 every motion is a bijection of $\mathbb{R}^n$, so $\mathrm{E}(n)$ is a subset of the group of all bijections $\mathbb{R}^n \to \mathbb{R}^n$ under composition, which is a group by the argument of Example (Groups) for S_n: composition of functions is associative by Theorem 0.4.2, the identity map is a two-sided identity, and a bijection has a two-sided inverse (Theorem 0.4.7), none of which used finiteness. It contains $\mathrm{id} = f_{\mathbf{I},\mathbf{0}}$, it is closed under composition by $(*)$ and because $\mathbf{RQ} \in \mathrm{O}(n)$ (Proposition 10.7.4), and it is closed under inverses by Corollary 21.4.2. By Definition 0.10.2 it is a subgroup, hence a group.

(b) With $\lambda(f_{\mathbf{Q},\mathbf{b}}) = \mathbf{Q}$, well defined by the uniqueness in Theorem 21.4.1, $(*)$ reads $\lambda(g \circ f) = \lambda(g)\lambda(f)$, so λ is a homomorphism (Definition 0.10.3). It is surjective because $\lambda(f_{\mathbf{Q},\mathbf{0}}) = \mathbf{Q}$ for every $\mathbf{Q} \in \mathrm{O}(n)$.

(c) $\lambda(f_{\mathbf{Q},\mathbf{b}}) = \mathbf{I}$ if and only if $\mathbf{Q} = \mathbf{I}$, that is, $f = t_{\mathbf{b}}$; so $\ker\lambda = \mathrm{Trans}(n)$. By $(*)$ with $\mathbf{R} = \mathbf{Q} = \mathbf{I}$, $t_{\mathbf{c}} \circ t_{\mathbf{b}} = t_{\mathbf{b}+\mathbf{c}}$, so $\mathbf{b} \mapsto t_{\mathbf{b}}$ is a homomorphism from $(\mathbb{R}^n, +)$; it is injective because $t_{\mathbf{b}} = \mathrm{id}$ forces $\mathbf{b} = t_{\mathbf{b}}(\mathbf{0}) = \mathbf{0}$, and its image is $\mathrm{Trans}(n)$ by definition.

(d) By Corollary 21.4.2, $f^{-1}(\mathbf{x}) = \mathbf{Q}^{\top}(\mathbf{x} - \mathbf{c})$ where $f = f_{\mathbf{Q},\mathbf{c}}$. Then

$$f\big(t_{\mathbf{b}}(f^{-1}(\mathbf{x}))\big) = \mathbf{Q}\big(\mathbf{Q}^{\top}(\mathbf{x} - \mathbf{c}) + \mathbf{b}\big) + \mathbf{c} = (\mathbf{x} - \mathbf{c}) + \mathbf{Qb} + \mathbf{c} = \mathbf{x} + \mathbf{Qb},$$

which is $t_{\mathbf{Qb}}(\mathbf{x})$. This proves the proposition.

■

Remark. In the vocabulary of group theory, (c) and (d) say that $\mathrm{Trans}(n)$ is a **normal** subgroup of $\mathrm{E}(n)$ and that the quotient group $\mathrm{E}(n)/\mathrm{Trans}(n)$ is isomorphic to $\mathrm{O}(n)$. This book has not built quotient groups — Chapter 3 §09's quotients are quotients of **vector spaces**, and $\mathrm{E}(n)$ is not one — so the proposition records instead the exact content such a quotient would package: a surjective homomorphism onto $\mathrm{O}(n)$ whose kernel is exactly the translations. Concretely, the motions with a given linear part $\mathbf{Q}$ are exactly the maps $t_{\mathbf{b}} \circ f_{\mathbf{Q},\mathbf{0}}$, one for each $\mathbf{b}$, which is the statement that the fibers of λ are the translates of its kernel.

Warning. $\mathrm{E}(n)$ **is not the direct product of** $\mathrm{O}(n)$ **and** $\mathrm{Trans}(n)$**.** Part (d) shows why: conjugating $t_{\mathbf{b}}$ by a rotation gives $t_{\mathbf{Qb}}$, not $t_{\mathbf{b}}$, so the two subgroups do **not** commute with one another. Concretely in $\mathbb{R}^2$, with $\mathbf{Q} = \mathbf{R}_{\pi/2}$ and $\mathbf{b} = \mathbf{e}_1$, the composite $f_{\mathbf{Q},\mathbf{0}} \circ t_{\mathbf{e}_1}$ sends $\mathbf{0}$ to $\mathbf{Qe}_1 = \mathbf{e}_2$, while $t_{\mathbf{e}_1} \circ f_{\mathbf{Q},\mathbf{0}}$ sends $\mathbf{0}$ to $\mathbf{e}_1$. A rotation followed by a translation is not the same motion as the translation followed by the rotation.

21.4.3 Motions of the plane

Now the classification. Four kinds of map appear, and each is built from a linear one by moving the origin to a chosen point.

Definition 21.4.3 — Translation, Rotation, Reflection, Glide Reflection

Let $\mathbf{p} \in \mathbb{R}^2$.

(a) The **translation** by $\mathbf{b}$ is $t_{\mathbf{b}}(\mathbf{x}) = \mathbf{x} + \mathbf{b}$.

(b) The **rotation about $\mathbf{p}$ by θ** is $\mathbf{x} \mapsto \mathbf{R}_\theta(\mathbf{x} - \mathbf{p}) + \mathbf{p}$.

(c) Let $L = \mathbf{p} + \operatorname{span}(\mathbf{u})$ be a line, $\mathbf{u} \neq \mathbf{0}$, and let $\mathbf{Q}_L \in \mathrm{O}(2)$ be the linear reflection fixing $\operatorname{span}(\mathbf{u})$ and negating $\operatorname{span}(\mathbf{u})^\perp$. The **reflection in** L is $s_L(\mathbf{x}) = \mathbf{Q}_L(\mathbf{x} - \mathbf{p}) + \mathbf{p}$.

(d) Let $\mathbf{v} \neq \mathbf{0}$ be parallel to L, that is, $\mathbf{v} \in \operatorname{span}(\mathbf{u})$. The **glide reflection** with axis L and vector $\mathbf{v}$ is $t_{\mathbf{v}} \circ s_L$.

The reflection s_L does not depend on which point $\mathbf{p} \in L$ is used: replacing $\mathbf{p}$ by $\mathbf{p} + c\mathbf{u}$ changes $\mathbf{Q}_L(\mathbf{x}-\mathbf{p})+\mathbf{p}$ by $-c\mathbf{Q}_L\mathbf{u}+c\mathbf{u} = \mathbf{0}$, since $\mathbf{Q}_L\mathbf{u} = \mathbf{u}$. All four maps are motions, being composites of translations and orthogonal maps. Their linear parts are $\mathbf{I}$, $\mathbf{R}_\theta$, $\mathbf{Q}_L$ and $\mathbf{Q}_L$, so the first two are direct and the last two are opposite.

Theorem 21.4.4 — Classification of the Motions of the Plane

Let $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ be a motion of $\mathbb{R}^2$. Then **exactly one** of the following holds.

(a) $f = \mathrm{id}$.

(b) $f = t_{\mathbf{b}}$ is a translation with $\mathbf{b} \neq \mathbf{0}$; the vector $\mathbf{b}$ is unique.

(c) f is a rotation about a point $\mathbf{p}$ by an angle $\theta \in (0, 2\pi)$; the point $\mathbf{p}$ and the angle θ are unique.

(d) f is a reflection s_L in a line L; the line L is unique.

(e) f is a glide reflection with axis L and vector $\mathbf{v} \neq \mathbf{0}$; the pair $(L, \mathbf{v})$ is unique.

The five cases are told apart by the determinant of $\mathbf{Q}$ and the fixed-point set $\operatorname{Fix}(f) = \{\mathbf{x} : f(\mathbf{x}) = \mathbf{x}\}$:

	(a)	(b)	(c)	(d)	(e)
$\det \mathbf{Q}$	1	1	1	-1	-1
$\operatorname{Fix}(f)$	$\mathbb{R}^2$	$\emptyset$	a point	a line	$\emptyset$

Idea. Split on $\det \mathbf{Q}$, which Theorem 10.7.5 turns into "$\mathbf{Q}$ is a rotation $\mathbf{R}_\theta$" or "$\mathbf{Q}$ is a linear reflection".

For $\det \mathbf{Q} = 1$ with $\mathbf{Q} \neq \mathbf{I}$, the matrix $\mathbf{I} - \mathbf{Q}$ is invertible, and solving $(\mathbf{I} - \mathbf{Q})\mathbf{p} = \mathbf{b}$ is exactly finding a fixed point; once there is one, moving the origin to it makes f linear.

For $\det \mathbf{Q} = -1$ there may be no fixed point, so instead split $\mathbf{b}$ into its components along the mirror and across it. The **across** part is absorbed by sliding the mirror halfway; the **along** part is what is left over, and it is the glide.

Proof. *Case* $\det \mathbf{Q} = 1$. By Theorem 10.7.5 (a), $\mathbf{Q} = \mathbf{R}_\theta$ for a unique $\theta \in [0, 2\pi)$.

If $\theta = 0$ then $\mathbf{Q} = \mathbf{I}$ and $f = t_{\mathbf{b}}$, which is case (a) when $\mathbf{b} = \mathbf{0}$ and case (b) otherwise; the vector is $\mathbf{b} = f(\mathbf{0})$, hence unique. Its fixed-point set is $\mathbb{R}^2$ or $\emptyset$.

If $\theta \neq 0$, then

$$\det(\mathbf{I} - \mathbf{R}_\theta) = (1 - \cos\theta)^2 + \sin^2\theta = 2 - 2\cos\theta.$$

Were this 0 we would have $\cos\theta = 1$, hence $\sin^2\theta = 1 - \cos^2\theta = 0$ and $\mathbf{R}_\theta = \mathbf{I} = \mathbf{R}_0$, so

$\theta = 0$ by the uniqueness in Theorem 10.7.5 (a), a contradiction. So $\mathbf{I} - \mathbf{Q}$ is invertible and there is a unique $\mathbf{p}$ with $(\mathbf{I} - \mathbf{Q})\mathbf{p} = \mathbf{b}$, that is, with $f(\mathbf{p}) = \mathbf{Q}\mathbf{p} + \mathbf{b} = \mathbf{p}$. For every $\mathbf{x}$,

$$f(\mathbf{x}) - \mathbf{p} = \mathbf{Q}\mathbf{x} + \mathbf{b} - \mathbf{p} = \mathbf{Q}\mathbf{x} - \mathbf{Q}\mathbf{p} = \mathbf{Q}(\mathbf{x} - \mathbf{p}),$$

so f is the rotation about $\mathbf{p}$ by θ: case (c). Its fixed points satisfy $(\mathbf{I} - \mathbf{Q})(\mathbf{x} - \mathbf{p}) = \mathbf{0}$, hence $\mathbf{x} = \mathbf{p}$, so $\mathrm{Fix}(f) = \{\mathbf{p}\}$ and $\mathbf{p}$ is determined by f; θ is determined because $\mathbf{Q}$ is.

Case $\det \mathbf{Q} = -1$. By Theorem 10.7.5 (b), $\mathbf{Q}$ fixes a line $\mathrm{span}(\mathbf{u})$ pointwise and negates $\mathrm{span}(\mathbf{u})^{\perp} = \mathrm{span}(\mathbf{w})$, where $(\mathbf{u}, \mathbf{w})$ is an orthonormal basis of $\mathbb{R}^2$. By Theorem 10.3.2 write

$$\mathbf{b} = \mathbf{b}_{\parallel} + \mathbf{b}_{\perp}, \qquad \mathbf{b}_{\parallel} = \langle \mathbf{b}, \mathbf{u} \rangle \mathbf{u}, \quad \mathbf{b}_{\perp} = \langle \mathbf{b}, \mathbf{w} \rangle \mathbf{w}.$$

Put $\mathbf{c} = \frac{1}{2}\mathbf{b}_{\perp}$ and $L = \mathbf{c} + \mathrm{span}(\mathbf{u})$. The reflection in L is $s_L(\mathbf{x}) = \mathbf{Q}(\mathbf{x} - \mathbf{c}) + \mathbf{c} = \mathbf{Q}\mathbf{x} + (\mathbf{I} - \mathbf{Q})\mathbf{c}$, and $\mathbf{Q}\mathbf{c} = -\mathbf{c}$ because $\mathbf{c} \in \mathrm{span}(\mathbf{w})$, so $(\mathbf{I} - \mathbf{Q})\mathbf{c} = 2\mathbf{c} = \mathbf{b}_{\perp}$ and

$$s_L(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}_{\perp}, \qquad f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}_{\perp} + \mathbf{b}_{\parallel} = \big(t_{\mathbf{b}_{\parallel}} \circ s_L\big)(\mathbf{x}).$$

If $\mathbf{b}_{\parallel} = \mathbf{0}$, then $f = s_L$: case (d). Its fixed set is L, since $\mathbf{Q}(\mathbf{x} - \mathbf{c}) = \mathbf{x} - \mathbf{c}$ holds exactly when $\mathbf{x} - \mathbf{c} \in \mathrm{span}(\mathbf{u})$; so L is determined by f.

If $\mathbf{b}_{\parallel} \neq \mathbf{0}$, then f is the glide reflection with axis L and vector $\mathbf{b}_{\parallel}$, which is parallel to L: case (e). For its fixed set, compute the square of f:

$$f(f(\mathbf{x})) = \mathbf{Q}(\mathbf{Q}\mathbf{x} + \mathbf{b}) + \mathbf{b} = \mathbf{x} + (\mathbf{Q}\mathbf{b} + \mathbf{b}) = \mathbf{x} + 2\mathbf{b}_{\parallel},$$

using $\mathbf{Q}^2 = \mathbf{I}$ and $\mathbf{Q}\mathbf{b} = \mathbf{b}_{\parallel} - \mathbf{b}_{\perp}$. So $f \circ f = t_{2\mathbf{b}_{\parallel}} \neq \mathrm{id}$, and a fixed point of f would be a fixed point of $f \circ f$; hence $\mathrm{Fix}(f) = \emptyset$.

Uniqueness in case (e). Suppose also $f = t_{\mathbf{v}} \circ s_{L'}$ with $\mathbf{v} \neq \mathbf{0}$ parallel to L'. Picking $\mathbf{p}' \in L'$ gives $f(\mathbf{x}) = \mathbf{Q}_{L'}\mathbf{x} + (\mathbf{I} - \mathbf{Q}_{L'})\mathbf{p}' + \mathbf{v}$, so comparing linear parts (unique by Theorem 21.4.1) gives $\mathbf{Q}_{L'} = \mathbf{Q}$, and hence L' has direction $\mathrm{span}(\mathbf{u})$ and $\mathbf{v} \in \mathrm{span}(\mathbf{u})$. Now $\mathbf{I} - \mathbf{Q}$ sends $\mathbf{u}$ to $\mathbf{0}$ and $\mathbf{w}$ to $2\mathbf{w}$, so $(\mathbf{I} - \mathbf{Q})\mathbf{p}' \in \mathrm{span}(\mathbf{w})$, and

$$\mathbf{b} = (\mathbf{I} - \mathbf{Q})\mathbf{p}' + \mathbf{v}, \qquad (\mathbf{I} - \mathbf{Q})\mathbf{p}' \in \mathrm{span}(\mathbf{w}), \quad \mathbf{v} \in \mathrm{span}(\mathbf{u}).$$

Comparing with $\mathbf{b} = \mathbf{b}_{\parallel} + \mathbf{b}_{\perp}$ and using the uniqueness of the decomposition in Theorem 10.3.2, $\mathbf{v} = \mathbf{b}_{\parallel}$. Finally $s_{L'} = t_{-\mathbf{v}} \circ f = s_L$, and a reflection determines its axis as its fixed set, so $L' = L$.

Exactly one case holds. The table follows from what was computed in each case, and it separates the five: within $\det \mathbf{Q} = 1$ the fixed sets $\mathbb{R}^2$, $\emptyset$, a single point are distinct, and within $\det \mathbf{Q} = -1$ a line and $\emptyset$ are distinct. This proves the theorem.

■

So there are only four shapes of plane motion, and the surprise is the fourth. A student asked to list them usually produces translations, rotations and reflections, and stops; the glide reflection is the one that has no fixed point and no visible center, and it is forced on us by the two-line computation $f \circ f = t_{2\mathbf{b}_{\parallel}}$.

Example. (Naming a plane motion)

Classify the motion $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ of $\mathbb{R}^2$ with

$$\mathbf{Q} = \tfrac{1}{5}\begin{pmatrix} -3 & 4 \\ 4 & 3 \end{pmatrix}, \qquad \mathbf{b} = (5, 0).$$

Solution. The linear part. The columns $\frac{1}{5}(-3, 4)$ and $\frac{1}{5}(4, 3)$ have norm $\frac{1}{5}\sqrt{9+16} = 1$ and inner product $\frac{1}{25}(-12 + 12) = 0$, so $\mathbf{Q} \in \mathrm{O}(2)$ by Theorem 10.7.3 (f), and $\det \mathbf{Q} = \frac{1}{25}(-9 - 16) = -1$. So f is opposite, and we are in case (d) or (e) of Theorem 21.4.4.

The mirror direction. Solve $\mathbf{Q}\mathbf{x} = \mathbf{x}$: the first row gives $-3x_1 + 4x_2 = 5x_1$, that is $x_2 = 2x_1$, and the second row gives $4x_1 + 3x_2 = 5x_2$, the same condition. So $\mathbf{Q}$ fixes $\mathrm{span}(\mathbf{u}')$ with $\mathbf{u}' = (1, 2)$, and negates $\mathrm{span}(\mathbf{w}')$ with $\mathbf{w}' = (2, -1)$: indeed $\mathbf{Q}(2, -1) = \frac{1}{5}(-6 - 4,\ 8 - 3) = (-2, 1)$.

Splitting $\mathbf{b}$. Since $\|\mathbf{u}'\|^2 = 5$,

$$\mathbf{b}_{\parallel} = \frac{\langle \mathbf{b}, \mathbf{u}' \rangle}{5}\mathbf{u}' = \frac{5}{5}(1, 2) = (1, 2), \qquad \mathbf{b}_{\perp} = \mathbf{b} - \mathbf{b}_{\parallel} = (4, -2) = 2\,\mathbf{w}'.$$

As $\mathbf{b}_{\parallel} \neq \mathbf{0}$, f is a **glide reflection**. Its axis is $L = \mathbf{c} + \mathrm{span}((1, 2))$ with $\mathbf{c} = \frac{1}{2}\mathbf{b}_{\perp} = (2, -1)$, and its vector is $(1, 2)$.

Checks. The point $(2, -1)$ should go to $(2, -1) + (1, 2) = (3, 1)$, and indeed $f(2, -1) = \frac{1}{5}(-6 - 4,\ 8 - 3) + (5, 0) = (-2, 1) + (5, 0) = (3, 1)$, which lies on L. And $f \circ f$ should be the translation by $2\mathbf{b}_{\parallel} = (2, 4)$: $f(f(\mathbf{x})) = \mathbf{x} + \mathbf{Q}\mathbf{b} + \mathbf{b}$, with $\mathbf{Q}\mathbf{b} = \frac{1}{5}(-15, 20) = (-3, 4)$, so $\mathbf{Q}\mathbf{b} + \mathbf{b} = (2, 4)$.

The next example is the one that explains where reflections sit in the group: they generate everything, and two of them make a direct motion.

Example. (Two mirrors)

(a) Reflect in the line $L_1 = \mathrm{span}((1, 0))$ and then in $L_2 = \mathrm{span}((1, 1))$. Identify the composite.

(b) Reflect in $M_1 = \{x_2 = 0\}$ and then in $M_2 = \{x_2 = 1\}$. Identify the composite.

(c) Prove the general statements: two reflections in lines through a common point $\mathbf{p}$ meeting at angle α compose to the rotation about $\mathbf{p}$ by 2α; two reflections in parallel lines compose to a translation by twice the perpendicular vector between them.

Solution.

(a) The reflection in the first coordinate axis is $\mathbf{Q}_1 = \mathrm{diag}(1, -1)$, and the reflection in the line $x_2 = x_1$ swaps the coordinates, $\mathbf{Q}_2 = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ (each fixes its line pointwise and negates the orthogonal complement, which is the description in Theorem 10.7.5 (b)). Then

$$\mathbf{Q}_2\mathbf{Q}_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = \mathbf{R}_{\pi/2}.$$

The two lines meet at angle $\pi/4$, and the composite is the rotation by $2 \cdot \pi/4 = \pi/2$ about their common point $\mathbf{0}$.

(b) $s_{M_1}(x_1, x_2) = (x_1, -x_2)$, and $s_{M_2}(x_1, x_2) = (x_1, 2 - x_2)$, since reflecting in the line

$x_2 = 1$ fixes the first coordinate and sends x_2 to $2 - x_2$. Composing, $s_{M_2}(s_{M_1}(\mathbf{x})) = (x_1, 2 + x_2)$, the translation by $(0, 2)$ — twice the perpendicular vector $(0, 1)$ from M_1 to M_2.

(c) Let $L_i = \mathbf{p} + \operatorname{span}(\mathbf{u}_i)$ with $\mathbf{u}_i$ unit vectors, meeting at $\mathbf{p}$. Moving the origin to $\mathbf{p}$ (that is, conjugating by $t_{-\mathbf{p}}$) we may assume $\mathbf{p} = \mathbf{0}$, because $s_{L_i} = t_{\mathbf{p}} \circ \mathbf{Q}_{L_i} \circ t_{-\mathbf{p}}$ and the two translations cancel in the middle of the composite. By Theorem 10.7.5 (b) the linear reflection in the line through $\mathbf{0}$ at angle φ is $\mathbf{M}_{2\varphi}$, the matrix with rows $(\cos 2\varphi, \sin 2\varphi)$ and $(\sin 2\varphi, -\cos 2\varphi)$. Writing $\mathbf{D} = \operatorname{diag}(1, -1)$, one checks $\mathbf{M}_\psi = \mathbf{R}_\psi \mathbf{D}$ and $\mathbf{D}\mathbf{R}_\psi\mathbf{D} = \mathbf{R}_{-\psi}$, the second because $\mathbf{D}$ changes the sign of $\sin\psi$ in both off-diagonal entries. Hence, for lines at angles φ_1 and φ_2 with $\alpha = \varphi_2 - \varphi_1$,

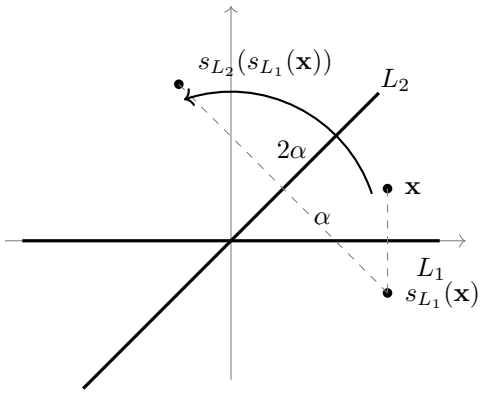
$$\mathbf{M}_{2\varphi_2}\mathbf{M}_{2\varphi_1} = \mathbf{R}_{2\varphi_2}\mathbf{D}\mathbf{R}_{2\varphi_1}\mathbf{D} = \mathbf{R}_{2\varphi_2}\mathbf{R}_{-2\varphi_1} = \mathbf{R}_{2\alpha},$$

a rotation about $\mathbf{0}$ by 2α; conjugating back gives the rotation about $\mathbf{p}$.

For parallel lines $L_i = \mathbf{c}_i + \operatorname{span}(\mathbf{u})$ the linear part is the same reflection $\mathbf{Q}$ for both, and $s_{L_i}(\mathbf{x}) = \mathbf{Q}\mathbf{x} + (\mathbf{I} - \mathbf{Q})\mathbf{c}_i$. Therefore

$$\begin{aligned} s_{L_2}\big(s_{L_1}(\mathbf{x})\big) &= \mathbf{Q}\big(\mathbf{Q}\mathbf{x} + (\mathbf{I} - \mathbf{Q})\mathbf{c}_1\big) + (\mathbf{I} - \mathbf{Q})\mathbf{c}_2 \\ &= \mathbf{x} + (\mathbf{Q} - \mathbf{I})\mathbf{c}_1 + (\mathbf{I} - \mathbf{Q})\mathbf{c}_2 = \mathbf{x} + (\mathbf{I} - \mathbf{Q})(\mathbf{c}_2 - \mathbf{c}_1), \end{aligned}$$

using $\mathbf{Q}^2 = \mathbf{I}$. Since $\mathbf{I} - \mathbf{Q}$ kills $\operatorname{span}(\mathbf{u})$ and doubles $\operatorname{span}(\mathbf{u})^\perp$, the vector $(\mathbf{I} - \mathbf{Q})(\mathbf{c}_2 - \mathbf{c}_1)$ is twice the component of $\mathbf{c}_2 - \mathbf{c}_1$ perpendicular to the lines. In (b), $\mathbf{c}_2 - \mathbf{c}_1 = (0, 1)$ and the translation was by $(0, 2)$.



Two mirrors meeting at angle α compose to the rotation through 2α about their common point

21.4.4 Motions of space

In $\mathbb{R}^3$ the same method works, with Corollary 11.6.2 supplying the normal form of the linear part. Two new names are needed.

Definition 21.4.4 — Screw Motion, Rotatory Reflection

Let $L = \mathbf{p} + \operatorname{span}(\mathbf{u})$ be a line in $\mathbb{R}^3$ with $\|\mathbf{u}\| = 1$, and let $\Pi = \mathbf{p} + W$ be a plane.

(a) A **rotation about the axis** L is a motion $\mathbf{x} \mapsto \mathbf{Q}(\mathbf{x}-\mathbf{p})+\mathbf{p}$ with $\mathbf{Q} \in \mathrm{SO}(3)$, $\mathbf{Q} \neq \mathbf{I}$ and $\mathbf{Q}\mathbf{u} = \mathbf{u}$. It fixes L pointwise, and by Corollary 11.6.2 it turns the plane $\mathrm{span}(\mathbf{u})^{\perp}$ by a single angle $\theta \in (0, \pi]$, the **angle** of the rotation. The requirement $\mathbf{Q} \neq \mathbf{I}$ keeps the identity out: it is a translation, and a translation should not also count as a rotation about every line at once.

(b) A **screw motion** is $t_{\mathbf{v}} \circ r$, where r is a rotation about L — so its angle is again non-zero — and $\mathbf{v} \neq \mathbf{0}$ is parallel to L.

(c) The **reflection in the plane** Π is $\mathbf{x} \mapsto \mathbf{Q}_{\Pi}(\mathbf{x}-\mathbf{p})+\mathbf{p}$, with $\mathbf{Q}_{\Pi}$ the linear map fixing W pointwise and negating $W^{\perp}$; a **glide reflection** is $t_{\mathbf{v}} \circ s_{\Pi}$ with $\mathbf{v} \neq \mathbf{0}$ lying in W.

(d) A **rotatory reflection about the point $\mathbf{p}$** is the composite of a rotation about an axis $L = \mathbf{p} + \mathrm{span}(\mathbf{u})$ by an angle $\theta \in (0, \pi]$ with the reflection in the plane $\mathbf{p} + \mathrm{span}(\mathbf{u})^{\perp}$ perpendicular to that axis. The two commute, and the composite is $\mathbf{x} \mapsto \mathbf{Q}(\mathbf{x}-\mathbf{p})+\mathbf{p}$ where $\mathbf{Q}$ is $[-1] \oplus \mathbf{R}_{\theta}$ in an orthonormal basis beginning with $\mathbf{u}$; in particular $\det \mathbf{Q} = -1$. The case $\theta = \pi$ gives $\mathbf{Q} = -\mathbf{I}_3$ and the **point reflection** $\mathbf{x} \mapsto 2\mathbf{p} - \mathbf{x}$.

Theorem 21.4.5 — Classification of the Motions of Space

Let $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ be a motion of $\mathbb{R}^3$.

(a) If f is direct, then f is a translation (possibly the identity), a rotation about an axis, or a screw motion, according as $\mathbf{Q} = \mathbf{I}$, or $\mathbf{Q} \neq \mathbf{I}$ and $\mathbf{b}$ is orthogonal to the line fixed by $\mathbf{Q}$, or $\mathbf{Q} \neq \mathbf{I}$ and it is not.

(b) If f is opposite, then f is a reflection in a plane, a glide reflection, or a rotatory reflection about a point.

In both parts the three cases are mutually exclusive, and are told apart by $\mathrm{Fix}(f)$ together with whether $\mathbf{Q} = \mathbf{I}$:

$\det \mathbf{Q} = 1$	translation	rotation	screw
$\mathrm{Fix}(f)$	$\mathbb{R}^3$ or $\emptyset$	a line	$\emptyset$
$\mathbf{Q}$	$\mathbf{I}$	$\neq \mathbf{I}$	$\neq \mathbf{I}$

$\det \mathbf{Q} = -1$	reflection	glide	rotatory
$\mathrm{Fix}(f)$	a plane	$\emptyset$	a point

Idea. Corollary 11.6.2 gives an orthonormal basis $(\mathbf{u}, \mathbf{w}_1, \mathbf{w}_2)$ in which $\mathbf{Q}$ is $[1] \oplus \mathbf{R}_{\theta}$ or $[-1] \oplus \mathbf{R}_{\theta}$ with $\theta \in [0, \pi]$. In every case, split $\mathbf{b}$ into its component along $\mathbf{u}$ and its component in $W = \mathrm{span}(\mathbf{u})^{\perp}$, and ask whether $\mathbf{I} - \mathbf{Q}$ can absorb each piece.

For a direct motion with $\theta \neq 0$, $\mathbf{I} - \mathbf{Q}$ kills $\mathbf{u}$ but is invertible on W; so the W-part of $\mathbf{b}$ is absorbed by moving the axis, and the $\mathbf{u}$-part survives as the glide along the axis. That is Chasles's screw.

For an opposite motion the roles swap. When $\theta = 0$, $\mathbf{Q}$ is a plane reflection: $\mathbf{I} - \mathbf{Q}$ is invertible on $\mathrm{span}(\mathbf{u})$ and kills W, so the $\mathbf{u}$-part of $\mathbf{b}$ is absorbed by sliding the mirror plane and the W-part survives as the glide. When $\theta \neq 0$, $\mathbf{I} - \mathbf{Q}$ is invertible outright, so **all** of $\mathbf{b}$ is absorbed and f has a fixed point.

Proof. By Corollary 11.6.2 there are an orthonormal basis $(\mathbf{u}, \mathbf{w}_1, \mathbf{w}_2)$ of $\mathbb{R}^3$ and $\theta \in [0, \pi]$ such that, in that basis, $\mathbf{Q}$ is $[1] \oplus \mathbf{R}_\theta$ when $\det \mathbf{Q} = 1$ and $[-1] \oplus \mathbf{R}_\theta$ when $\det \mathbf{Q} = -1$. Put $W = \operatorname{span}(\mathbf{u})^\perp = \operatorname{span}(\mathbf{w}_1, \mathbf{w}_2)$, a $\mathbf{Q}$-invariant subspace on which $\mathbf{Q}$ acts as $\mathbf{R}_\theta$ in the basis $(\mathbf{w}_1, \mathbf{w}_2)$, and write, by Theorem 10.3.2,

$$\mathbf{b} = \mathbf{b}_\parallel + \mathbf{b}_\perp, \qquad \mathbf{b}_\parallel = \langle \mathbf{b}, \mathbf{u} \rangle \mathbf{u}, \quad \mathbf{b}_\perp \in W.$$

As in the proof of Theorem 21.4.4, $\det(\mathbf{I}_2 - \mathbf{R}_\theta) = 2 - 2\cos\theta$, which is non-zero exactly when $\mathbf{R}_\theta \neq \mathbf{I}_2$, that is, when $\theta \neq 0$.

(a) Direct motions. Here $\mathbf{Q}\mathbf{u} = \mathbf{u}$.

If $\theta = 0$, then $\mathbf{Q} = \mathbf{I}$ and $f = t_{\mathbf{b}}$, the identity when $\mathbf{b} = \mathbf{0}$. Its fixed set is $\mathbb{R}^3$ or $\emptyset$.

If $\theta \neq 0$, then $\mathbf{Q} \neq \mathbf{I}$ and the restriction of $\mathbf{I} - \mathbf{Q}$ to W has matrix $\mathbf{I}_2 - \mathbf{R}_\theta$, which is invertible. Since $\mathbf{b}_\perp \in W$, there is a unique $\mathbf{c} \in W$ with $(\mathbf{I} - \mathbf{Q})\mathbf{c} = \mathbf{b}_\perp$. Put $L = \mathbf{c} + \operatorname{span}(\mathbf{u})$ and $r(\mathbf{x}) = \mathbf{Q}(\mathbf{x} - \mathbf{c}) + \mathbf{c} = \mathbf{Q}\mathbf{x} + (\mathbf{I} - \mathbf{Q})\mathbf{c} = \mathbf{Q}\mathbf{x} + \mathbf{b}_\perp$. Then r fixes L pointwise, because $r(\mathbf{c} + s\mathbf{u}) = \mathbf{Q}(s\mathbf{u}) + \mathbf{c} = s\mathbf{u} + \mathbf{c}$, so r is the rotation about the axis L. And

$$f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}_\perp + \mathbf{b}_\parallel = \big(t_{\mathbf{b}_\parallel} \circ r\big)(\mathbf{x}),$$

with $\mathbf{b}_\parallel$ parallel to L. So $f = r$ is a rotation about L when $\mathbf{b}_\parallel = \mathbf{0}$, and a screw motion otherwise.

For the fixed sets, note that $(\mathbf{I} - \mathbf{Q})\mathbf{x} \in W$ for every $\mathbf{x}$, because $(\mathbf{I} - \mathbf{Q})\mathbf{u} = \mathbf{0}$ and $\mathbf{I} - \mathbf{Q}$ maps W into W. Hence the $\mathbf{u}$-component of $f(\mathbf{x}) - \mathbf{x} = \mathbf{b} - (\mathbf{I} - \mathbf{Q})\mathbf{x}$ is $\mathbf{b}_\parallel$. If $\mathbf{b}_\parallel \neq \mathbf{0}$ there is no fixed point; if $\mathbf{b}_\parallel = \mathbf{0}$ the fixed points are the $\mathbf{x}$ with $(\mathbf{I} - \mathbf{Q})\mathbf{x} = \mathbf{b}_\perp$, whose W-component is the unique $\mathbf{c}$ above and whose $\mathbf{u}$-component is free, that is, the line L.

(b) Opposite motions. Here $\mathbf{Q}\mathbf{u} = -\mathbf{u}$.

If $\theta = 0$, then $\mathbf{Q}$ fixes W pointwise and negates $\operatorname{span}(\mathbf{u})$: it is the linear reflection in the plane W. Put $\mathbf{c} = \frac{1}{2}\mathbf{b}_\parallel \in \operatorname{span}(\mathbf{u})$ and $\Pi = \mathbf{c} + W$. Since $\mathbf{Q}\mathbf{c} = -\mathbf{c}$ we get $(\mathbf{I} - \mathbf{Q})\mathbf{c} = 2\mathbf{c} = \mathbf{b}_\parallel$, so the reflection in Π is

$$s_\Pi(\mathbf{x}) = \mathbf{Q}(\mathbf{x} - \mathbf{c}) + \mathbf{c} = \mathbf{Q}\mathbf{x} + \mathbf{b}_\parallel, \qquad f(\mathbf{x}) = \big(t_{\mathbf{b}_\perp} \circ s_\Pi\big)(\mathbf{x}),$$

with $\mathbf{b}_\perp \in W$ parallel to Π. So f is the reflection in Π when $\mathbf{b}_\perp = \mathbf{0}$, and a glide reflection otherwise. For the fixed sets: $(\mathbf{I} - \mathbf{Q})\mathbf{x} \in \operatorname{span}(\mathbf{u})$ for every $\mathbf{x}$, since $\mathbf{I} - \mathbf{Q}$ kills W, so the W-component of $f(\mathbf{x}) - \mathbf{x}$ is $\mathbf{b}_\perp$. If $\mathbf{b}_\perp \neq \mathbf{0}$ there is no fixed point; if $\mathbf{b}_\perp = \mathbf{0}$ the fixed points are the $\mathbf{x}$ with $(\mathbf{I} - \mathbf{Q})\mathbf{x} = \mathbf{b}_\parallel$, that is, with $\mathbf{u}$-component $\mathbf{c}$, which is the plane Π.

If $\theta \neq 0$, then in the basis $(\mathbf{u}, \mathbf{w}_1, \mathbf{w}_2)$ the matrix $\mathbf{I}_3 - \mathbf{Q}$ is $[2] \oplus (\mathbf{I}_2 - \mathbf{R}_\theta)$, whose determinant is $2(2 - 2\cos\theta) \neq 0$. So $\mathbf{I} - \mathbf{Q}$ is invertible and there is a unique $\mathbf{p}$ with $(\mathbf{I} - \mathbf{Q})\mathbf{p} = \mathbf{b}$, that is, $f(\mathbf{p}) = \mathbf{p}$. Then $f(\mathbf{x}) - \mathbf{p} = \mathbf{Q}(\mathbf{x} - \mathbf{p})$ for every $\mathbf{x}$, as in the plane case, and f is a rotatory reflection about $\mathbf{p}$: in the basis $(\mathbf{u}, \mathbf{w}_1, \mathbf{w}_2)$ its linear part is $[-1] \oplus \mathbf{R}_\theta$, the rotation by θ about $\operatorname{span}(\mathbf{u})$ followed by the reflection in W, and these two commute. The fixed set is $\{\mathbf{p}\}$, since $\mathbf{I} - \mathbf{Q}$ is injective. When $\theta = \pi$, $\mathbf{R}_\pi = -\mathbf{I}_2$ and $\mathbf{Q} = -\mathbf{I}_3$, giving the point reflection $\mathbf{x} \mapsto 2\mathbf{p} - \mathbf{x}$.

Finally, exactly one case holds in each part. Among the direct motions a translation has $\mathbf{Q} = \mathbf{I}$ while a rotation and a screw do not, and those two differ by having a line of fixed points or none; among the opposite motions the three fixed sets, a plane, the empty set and a single point, are pairwise different. This proves the theorem.

■

Remark. Part (a) is **Chasles's theorem**: every direct motion of space is a screw, provided the two degenerate cases barred by Definition 21.4.4 are allowed back in — angle $\theta = 0$, which is a pure translation, and $\mathbf{v} = \mathbf{0}$, which is a pure rotation. The corresponding statement in the plane, Theorem 21.4.4, has no screw because a rotation of $\mathbb{R}^2$ leaves no axis to glide along.

Warning. **From $\mathbb{R}^4$ on, the list breaks down.** The proof rested entirely on Corollary 11.6.2, which in turn rested on the arithmetic $p + q + 2m = 3$ of Theorem 11.6.1. In $\mathbb{R}^4$ the matrix $\mathbf{R}_{\pi/2} \oplus \mathbf{R}_{\pi/3}$ has determinant 1 and fixes no non-zero vector, so a direct motion of $\mathbb{R}^4$ need not have an axis and need not be a screw. The right general statement replaces "one axis and one angle" by the full canonical form: a **direct** motion of $\mathbb{R}^n$ decomposes the space into a flat, along which it translates, and a list of mutually orthogonal planes, each turned by its own angle. The word **direct** is needed there: that description hides the $-\mathbf{I}_q$ block of Theorem 11.6.1, which splits into rotations by π only when q is even, and an opposite motion keeps one leftover direction and negates it. The glide reflection of Theorem 21.4.5 (b) is the smallest witness, with $p = 2$, $q = 1$, $m = 0$: it has no rotation plane, yet it is not a pure translation. This book proves the classification only for $n \le 3$.

Example. (Naming a space motion)

Classify the motion $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ of $\mathbb{R}^3$ with

$$\mathbf{Q} = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \qquad \mathbf{b} = (4, 1, -2).$$

Solution. The linear part. The columns of $\mathbf{Q}$ are $\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1$, an orthonormal list, so $\mathbf{Q} \in \mathrm{O}(3)$ by Theorem 10.7.3 (f). Expanding along the first row, $\det \mathbf{Q} = 0 - 0 + 1 \cdot (1 \cdot 1 - 0 \cdot 0) = 1$, so f is direct. By Theorem 11.6.4 (c), $\mathbf{Q} = \mathbf{R}_{\mathbf{n},\theta}$ for some unit $\mathbf{n}$ and $\theta \in [0, \pi]$. Its trace is 0, so by Theorem 11.6.5 (a) the angle is given by $\cos\theta = \frac{1}{2}(0 - 1) = -\frac{1}{2}$, that is $\theta = 2\pi/3$, and in particular $\mathbf{Q} \neq \mathbf{I}$. The axis direction is fixed by $\mathbf{Q}$: reading $\mathbf{Q}\mathbf{x} = (x_3, x_1, x_2)$, the equation $\mathbf{Q}\mathbf{x} = \mathbf{x}$ says $x_1 = x_2 = x_3$, so the axis direction is $\mathbf{u}' = (1, 1, 1)$.

Splitting $\mathbf{b}$. With $\|\mathbf{u}'\|^2 = 3$ and $\langle \mathbf{b}, \mathbf{u}' \rangle = 4 + 1 - 2 = 3$,

$$\mathbf{b}_{\parallel} = \tfrac{3}{3}(1, 1, 1) = (1, 1, 1), \qquad \mathbf{b}_{\perp} = \mathbf{b} - \mathbf{b}_{\parallel} = (3, 0, -3).$$

Since $\mathbf{b}_{\parallel} \neq \mathbf{0}$, Theorem 21.4.5 (a) says f is a **screw motion** with glide vector $(1, 1, 1)$.

The axis. We need $\mathbf{c}$ perpendicular to $\mathbf{u}'$ with $(\mathbf{I} - \mathbf{Q})\mathbf{c} = \mathbf{b}_{\perp}$. Writing $(\mathbf{I} - \mathbf{Q})\mathbf{c} = (c_1 - c_3,\ c_2 - c_1,\ c_3 - c_2)$, the equations are $c_1 - c_3 = 3$, $c_2 - c_1 = 0$, $c_3 - c_2 = -3$, together with $c_1 + c_2 + c_3 = 0$. From the second, $c_2 = c_1$; from the first, $c_3 = c_1 - 3$; the sum gives $3c_1 - 3 = 0$, so $\mathbf{c} = (1, 1, -2)$. The axis is $L = (1, 1, -2) + \mathrm{span}((1, 1, 1))$.

Checks. The rotation part $r(\mathbf{x}) = \mathbf{Q}\mathbf{x} + (3, 0, -3)$ should fix $\mathbf{c}$: $\mathbf{Q}(1, 1, -2) = (-2, 1, 1)$, and $(-2, 1, 1) + (3, 0, -3) = (1, 1, -2)$. And f applied three times should be the trans-

lation by $3\mathbf{b}_{\|} = (3,3,3)$, since $\mathbf{Q}^3 = \mathbf{I}$:

$$f^3(\mathbf{x}) = \mathbf{Q}^3\mathbf{x} + \mathbf{Q}^2\mathbf{b} + \mathbf{Q}\mathbf{b} + \mathbf{b} = \mathbf{x} + (\mathbf{I} + \mathbf{Q} + \mathbf{Q}^2)\mathbf{b}.$$

Here $\mathbf{I} + \mathbf{Q} + \mathbf{Q}^2$ is the all-ones matrix $\mathbf{J}$, so $(\mathbf{I} + \mathbf{Q} + \mathbf{Q}^2)\mathbf{b} = (4 + 1 - 2)\mathbf{1} = (3,3,3)$, as predicted.

21.4.5 Exercises

21.4.5.1 A. Check your understanding

Exercise A1.

(a) State Definition 21.4.1, and say which of linearity, continuity and surjectivity it assumes.

(b) True or false: every motion of $\mathbb{R}^n$ with a fixed point is linear. Justify your answer.

(c) Name the four kinds of motion of $\mathbb{R}^2$ and give the fixed-point set of each.

(d) True or false: the composite of two opposite motions of $\mathbb{R}^3$ is opposite. Justify your answer.

(e) A motion of $\mathbb{R}^3$ has exactly one fixed point. What kind is it?

Solution.

(a) A motion is a map $f\colon \mathbb{R}^n \to \mathbb{R}^n$ with $\|f(\mathbf{x}) - f(\mathbf{y})\| = \|\mathbf{x} - \mathbf{y}\|$ for all $\mathbf{x}, \mathbf{y}$. It assumes none of the three: Theorem 21.4.1 shows that a motion is automatically affine, and Corollary 21.4.2 that it is automatically a bijection.

(b) False as stated, but only just: by Theorem 21.4.1, $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$, and $f(\mathbf{p}) = \mathbf{p}$ gives $\mathbf{b} = \mathbf{p} - \mathbf{Q}\mathbf{p}$, so $f(\mathbf{x}) = \mathbf{Q}(\mathbf{x} - \mathbf{p}) + \mathbf{p}$, which is linear precisely when $\mathbf{p}$ can be taken to be $\mathbf{0}$. For example the half-turn of $\mathbb{R}^2$ about $(1,0)$, $\mathbf{x} \mapsto -\mathbf{x} + (2,0)$, has a fixed point but sends $\mathbf{0}$ to $(2,0) \neq \mathbf{0}$, so it is not linear. What is true is that a motion fixing $\mathbf{0}$ is linear, which is Steps 1 to 3 of Theorem 21.4.1.

(c) Translations (fixed set $\mathbb{R}^2$ if the identity, otherwise $\emptyset$); rotations about a point (one point); reflections in a line (that line); glide reflections ($\emptyset$). This is Theorem 21.4.4.

(d) False. By Proposition 21.4.3 (b) the linear part of a composite is the product of the linear parts, and det is multiplicative (Theorem 6.5.4), so the composite has det $= (-1)(-1) = 1$ and is **direct**. What composes is the parity, not the word "opposite": Example (Two mirrors) is the two-dimensional instance, where two reflections make a rotation.

(e) A rotatory reflection about that point, by Theorem 21.4.5: it is the only kind whose fixed set is a single point. In particular it is opposite.

21.4.5.2 B. Practice

Exercise B1: Classify three plane motions.

Classify each motion $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ of $\mathbb{R}^2$, giving the center and angle, the axis, or the axis and glide vector, as appropriate.

(a) $\mathbf{Q} = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, $\mathbf{b} = (2, 4)$.
(b) $\mathbf{Q} = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, $\mathbf{b} = (3, 3)$.
(c) $\mathbf{Q} = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, $\mathbf{b} = (1, -1)$.

Solution.

(a) $\det \mathbf{Q} = 1$ and $\mathbf{Q} = \mathbf{R}_{\pi/2}$, so f is a rotation by $\pi/2$. Its center solves $(\mathbf{I} - \mathbf{Q})\mathbf{p} = \mathbf{b}$, that is $p_1 + p_2 = 2$ and $-p_1 + p_2 = 4$; adding gives $2p_2 = 6$, so $\mathbf{p} = (-1, 3)$. Check: $f(-1, 3) = (-3, -1) + (2, 4) = (-1, 3)$. So f is the rotation about $(-1, 3)$ by $\pi/2$.

(b) $\det \mathbf{Q} = -1$, and $\mathbf{Q}$ swaps the coordinates: it is the reflection in $\operatorname{span}((1, 1))$, negating $\operatorname{span}((1, -1))$. With $\mathbf{u}' = (1, 1)$, $\langle \mathbf{b}, \mathbf{u}' \rangle = 6$ and $\|\mathbf{u}'\|^2 = 2$, so $\mathbf{b}_{\|} = 3(1, 1) = (3, 3) = \mathbf{b}$ and $\mathbf{b}_{\perp} = \mathbf{0}$. Since $\mathbf{b}_{\|} \neq \mathbf{0}$, f is a glide reflection with axis $\mathbf{c} + \operatorname{span}((1, 1))$, where $\mathbf{c} = \frac{1}{2}\mathbf{b}_{\perp} = \mathbf{0}$: the axis is the line $x_2 = x_1$ and the glide vector is $(3, 3)$. Check: $f(0, 0) = (3, 3)$, which is on the axis.

(c) Same $\mathbf{Q}$. Now $\langle \mathbf{b}, \mathbf{u}' \rangle = 0$, so $\mathbf{b}_{\|} = \mathbf{0}$ and $\mathbf{b}_{\perp} = (1, -1)$. Hence f is a **reflection**, in the line $L = \mathbf{c} + \operatorname{span}((1, 1))$ with $\mathbf{c} = \frac{1}{2}(1, -1)$. Check: $f(\frac{1}{2}, -\frac{1}{2}) = (-\frac{1}{2}, \frac{1}{2}) + (1, -1) = (\frac{1}{2}, -\frac{1}{2})$, a fixed point, and $f(\frac{3}{2}, \frac{1}{2}) = (\frac{1}{2}, \frac{3}{2}) + (1, -1) = (\frac{3}{2}, \frac{1}{2})$, another one; the two lie on L.

Exercise B2: A space motion.

Classify the motion $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ of $\mathbb{R}^3$ with

$$\mathbf{Q} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \qquad \mathbf{b} = (0, 2, 0),$$

giving the axis and the glide vector if there is one.

Solution. The columns are $\mathbf{e}_1, \mathbf{e}_3, -\mathbf{e}_2$, orthonormal, so $\mathbf{Q} \in \mathrm{O}(3)$; expanding along the first row, $\det \mathbf{Q} = 1 \cdot (0 + 1) = 1$, so f is direct. The fixed vectors of $\mathbf{Q}$ satisfy x_1 free, $-x_3 = x_2$, $x_2 = x_3$, hence $x_2 = x_3 = 0$: the axis direction is $\mathbf{u} = \mathbf{e}_1$, and $\mathbf{Q}$ is the quarter turn about it.

Now $\mathbf{b}_{\|} = \langle \mathbf{b}, \mathbf{e}_1 \rangle \mathbf{e}_1 = \mathbf{0}$ and $\mathbf{b}_{\perp} = (0, 2, 0)$. Since $\mathbf{b}_{\|} = \mathbf{0}$, Theorem 21.4.5 (a) says f is a **pure rotation** about an axis, with no glide. The axis is $\mathbf{c} + \operatorname{span}(\mathbf{e}_1)$ where $\mathbf{c} \in \operatorname{span}(\mathbf{e}_2, \mathbf{e}_3)$ solves $(\mathbf{I} - \mathbf{Q})\mathbf{c} = \mathbf{b}_{\perp}$:

$$(\mathbf{I} - \mathbf{Q})(0, c_2, c_3) = (0,\ c_2 + c_3,\ -c_2 + c_3) = (0, 2, 0)$$

gives $c_2 + c_3 = 2$ and $c_3 = c_2$, so $\mathbf{c} = (0, 1, 1)$. The axis is $\{(t, 1, 1) : t \in \mathbb{R}\}$. Check: $f(0, 1, 1) = (0, -1, 1) + (0, 2, 0) = (0, 1, 1)$, and $f(5, 1, 1) = (5, -1, 1) + (0, 2, 0) = (5, 1, 1)$.

Exercise B3: A motion is determined by few points.

Let f and g be motions of $\mathbb{R}^n$ that agree on $\mathbf{0}, \mathbf{e}_1, \ldots, \mathbf{e}_n$. Prove that $f = g$.

Hint: consider $h = g^{-1} \circ f$ and use Theorem 21.4.1.

Solution. By Corollary 21.4.2, g^{-1} is a motion, so $h = g^{-1} \circ f$ is a motion (example 3 after Definition 21.4.1). It fixes $\mathbf{0}$ and each $\mathbf{e}_i$, since f and g agree there. By Theorem 21.4.1, $h(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ with $\mathbf{Q} \in \mathrm{O}(n)$; from $h(\mathbf{0}) = \mathbf{0}$ we get $\mathbf{b} = \mathbf{0}$, and then $\mathbf{Q}\mathbf{e}_i = h(\mathbf{e}_i) = \mathbf{e}_i$ for each i, so $\mathbf{Q}$ agrees with $\mathbf{I}$ on a basis and $\mathbf{Q} = \mathbf{I}$. Hence $h = \mathrm{id}$, and composing with g gives $f = g$.

(The $n+1$ points $\mathbf{0}, \mathbf{e}_1, \dots, \mathbf{e}_n$ are affinely independent, and the same argument works for any affinely independent list of $n+1$ points, which is the affine statement of §02.)

21.4.5.3 C. Going deeper

Exercise C1: Reflections generate the motions.

(a) Prove that every motion of $\mathbb{R}^n$ is a composite of at most $n+1$ reflections in affine hyperplanes, where the reflection in the hyperplane $\mathbf{p} + \mathrm{span}(\mathbf{w})^{\perp}$ is $\mathbf{x} \mapsto \mathbf{H}_{\mathbf{w}}(\mathbf{x} - \mathbf{p}) + \mathbf{p}$ with $\mathbf{H}_{\mathbf{w}}$ the Householder reflection of Definition 10.8.1.

(b) Deduce that a translation of $\mathbb{R}^n$ by $\mathbf{b} \neq \mathbf{0}$ is a composite of exactly two such reflections, and identify them.

Hint: for (a), first make the motion fix a point, then quote Theorem 11.6.7.

Solution.

(a) Write $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ by Theorem 21.4.1. If $\mathbf{b} = \mathbf{0}$, then $\mathbf{Q}$ is a product of at most n Householder reflections by Theorem 11.6.7, and each of those is the reflection in the hyperplane $\mathbf{0} + \mathrm{span}(\mathbf{w})^{\perp}$ in the above sense, so f is a composite of at most $n \le n+1$ reflections.
If $\mathbf{b} \neq \mathbf{0}$, let σ be the reflection in the hyperplane $\frac{1}{2}\mathbf{b} + \mathrm{span}(\mathbf{b})^{\perp}$, that is, $\sigma(\mathbf{x}) = \mathbf{H}_{\mathbf{b}}(\mathbf{x} - \frac{1}{2}\mathbf{b}) + \frac{1}{2}\mathbf{b}$. Since $\mathbf{H}_{\mathbf{b}}\mathbf{b} = -\mathbf{b}$ (Proposition 10.8.2 (d)), this simplifies to $\sigma(\mathbf{x}) = \mathbf{H}_{\mathbf{b}}\mathbf{x} + \mathbf{b}$, and then, using $\mathbf{H}_{\mathbf{b}}^2 = \mathbf{I}$ (Proposition 10.8.2 (b)),

$$\sigma\big(\sigma(\mathbf{x})\big) = \mathbf{H}_{\mathbf{b}}\big(\mathbf{H}_{\mathbf{b}}\mathbf{x} + \mathbf{b}\big) + \mathbf{b} = \mathbf{x} - \mathbf{b} + \mathbf{b} = \mathbf{x},$$

so $\sigma^{-1} = \sigma$. Therefore

$$(\sigma \circ f)(\mathbf{x}) = \mathbf{H}_{\mathbf{b}}(\mathbf{Q}\mathbf{x} + \mathbf{b}) + \mathbf{b} = \mathbf{H}_{\mathbf{b}}\mathbf{Q}\mathbf{x} - \mathbf{b} + \mathbf{b} = \mathbf{H}_{\mathbf{b}}\mathbf{Q}\mathbf{x},$$

a linear orthogonal map, which by Theorem 11.6.7 is a product of at most n Householder reflections. Hence $f = \sigma \circ (\sigma \circ f)$ is a composite of at most $n+1$ reflections.

(b) Let $f = t_{\mathbf{b}}$ with $\mathbf{b} \neq \mathbf{0}$. It is not a single reflection, since a reflection has a fixed point and $t_{\mathbf{b}}$ has none. Let σ_0 be the reflection in $\mathrm{span}(\mathbf{b})^{\perp}$ and σ_1 the reflection in $\frac{1}{2}\mathbf{b} + \mathrm{span}(\mathbf{b})^{\perp}$. By the computation in (a), $\sigma_0(\mathbf{x}) = \mathbf{H}_{\mathbf{b}}\mathbf{x}$ and $\sigma_1(\mathbf{x}) = \mathbf{H}_{\mathbf{b}}\mathbf{x} + \mathbf{b}$, so

$$(\sigma_1 \circ \sigma_0)(\mathbf{x}) = \mathbf{H}_{\mathbf{b}}\big(\mathbf{H}_{\mathbf{b}}\mathbf{x}\big) + \mathbf{b} = \mathbf{x} + \mathbf{b} = t_{\mathbf{b}}(\mathbf{x}).$$

So exactly two reflections suffice, in two parallel hyperplanes perpendicular to $\mathbf{b}$ and at distance $\frac{1}{2}\|\mathbf{b}\|$ apart — the n-dimensional form of Example (Two mirrors) (b).

Exercise C2: Matching two congruent frames.

Let $\mathbf{p}_0, \dots, \mathbf{p}_n$ and $\mathbf{q}_0, \dots, \mathbf{q}_n$ be points of $\mathbb{R}^n$ with $\|\mathbf{p}_i - \mathbf{p}_j\| = \|\mathbf{q}_i - \mathbf{q}_j\|$ for all i, j, and suppose $\mathbf{p}_1 - \mathbf{p}_0, \dots, \mathbf{p}_n - \mathbf{p}_0$ is a basis of $\mathbb{R}^n$.

(a) Prove that there is a motion f of $\mathbb{R}^n$ with $f(\mathbf{p}_i) = \mathbf{q}_i$ for every i.

(b) Prove that f is unique, and give an example with fewer points where it is not.

Hint: for (a), translate both lists so that $\mathbf{p}_0 = \mathbf{q}_0 = \mathbf{0}$, then compare the inner products of the two lists.

Solution.

(a) Replacing $\mathbf{p}_i$ by $\mathbf{p}_i - \mathbf{p}_0$ and $\mathbf{q}_i$ by $\mathbf{q}_i - \mathbf{q}_0$ changes no distance, and undoing the two translations at the end changes a motion into a motion; so assume $\mathbf{p}_0 = \mathbf{q}_0 = \mathbf{0}$. Put $\mathbf{v}_i = \mathbf{p}_i$ and $\mathbf{w}_i = \mathbf{q}_i$ for $i \geq 1$. Taking $j = 0$ in the hypothesis gives $\|\mathbf{v}_i\| = \|\mathbf{w}_i\|$, and then for $i, j \geq 1$, by Theorem 10.1.2 (c),

$$\begin{aligned} 2\langle \mathbf{v}_i, \mathbf{v}_j \rangle &= \|\mathbf{v}_i\|^2 + \|\mathbf{v}_j\|^2 - \|\mathbf{v}_i - \mathbf{v}_j\|^2 \\ &= \|\mathbf{w}_i\|^2 + \|\mathbf{w}_j\|^2 - \|\mathbf{w}_i - \mathbf{w}_j\|^2 = 2\langle \mathbf{w}_i, \mathbf{w}_j \rangle. \end{aligned}$$

So the two lists have the same inner products. Since $(\mathbf{v}_1, \dots, \mathbf{v}_n)$ is a basis, Theorem 3.1.5 gives a unique linear T with $T\mathbf{v}_i = \mathbf{w}_i$, and for $\mathbf{x} = \sum_i x_i \mathbf{v}_i$,

$$\|T\mathbf{x}\|^2 = \sum_{i,j} x_i x_j \langle \mathbf{w}_i, \mathbf{w}_j \rangle = \sum_{i,j} x_i x_j \langle \mathbf{v}_i, \mathbf{v}_j \rangle = \|\mathbf{x}\|^2,$$

where both ends use Theorem 10.1.2 (c) repeatedly to expand a squared norm of a sum. So T is an isometry, and $f(\mathbf{x}) = T\mathbf{x}$ is a motion with $f(\mathbf{p}_i) = \mathbf{q}_i$ for $i \geq 1$ and $f(\mathbf{0}) = \mathbf{0}$.

(b) If f and g are motions with $f(\mathbf{p}_i) = g(\mathbf{p}_i) = \mathbf{q}_i$ for all i, then $h = g^{-1} \circ f$ is a motion (Corollary 21.4.2) fixing every $\mathbf{p}_i$. Write $h(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$ by Theorem 21.4.1. Subtracting $h(\mathbf{p}_0) = \mathbf{p}_0$ from $h(\mathbf{p}_i) = \mathbf{p}_i$ gives $\mathbf{Q}(\mathbf{p}_i - \mathbf{p}_0) = \mathbf{p}_i - \mathbf{p}_0$ for $i \geq 1$, so $\mathbf{Q}$ fixes a basis and $\mathbf{Q} = \mathbf{I}$; then $\mathbf{b} = \mathbf{p}_0 - \mathbf{p}_0 = \mathbf{0}$ and $h = \mathrm{id}$, so $f = g$.

With fewer points the spanning hypothesis fails and uniqueness goes with it. In $\mathbb{R}^2$, take the single pair $\mathbf{p}_0 = \mathbf{q}_0 = (0, 0)$ and $\mathbf{p}_1 = \mathbf{q}_1 = (1, 0)$. Both the identity and the reflection in the first coordinate axis are motions carrying $\mathbf{p}_i$ to $\mathbf{q}_i$, and they differ at $(0, 1)$. Here $\mathbf{p}_1 - \mathbf{p}_0 = \mathbf{e}_1$ spans only a line.

Exercise C3: Motions of a finite set.

Let $S \subseteq \mathbb{R}^n$ be a finite non-empty set and let $G = \{f \in \mathrm{E}(n) : f(S) = S\}$ be its symmetry group.

(a) Prove that G is a subgroup of $\mathrm{E}(n)$, and that every $f \in G$ fixes the **centroid** $\mathbf{c} = \frac{1}{|S|} \sum_{\mathbf{p} \in S} \mathbf{p}$.

(b) Deduce that G is isomorphic to a subgroup of $\mathrm{O}(n)$, and that G contains no translation other than the identity.

Solution.

(a) The identity lies in G. If $f, g \in G$ then $(g \circ f)(S) = g(S) = S$, and $f(S) = S$ with f a bijection (Corollary 21.4.2) gives $f^{-1}(S) = S$; so G is a subgroup by Definition 0.10.2, using Proposition 21.4.3 (a).
Let $f \in G$, with $f(\mathbf{x}) = \mathbf{Q}\mathbf{x} + \mathbf{b}$. Since f restricts to a bijection of the finite set S,

$$\sum_{\mathbf{p}\in S} f(\mathbf{p}) = \sum_{\mathbf{q}\in S} \mathbf{q} = |S|\,\mathbf{c},$$

while on the other hand $\sum_{\mathbf{p}\in S} f(\mathbf{p}) = \mathbf{Q}\big(\sum_{\mathbf{p}\in S} \mathbf{p}\big) + |S|\mathbf{b} = |S|(\mathbf{Q}\mathbf{c}+\mathbf{b}) = |S| f(\mathbf{c})$. Dividing by $|S| \neq 0$ gives $f(\mathbf{c}) = \mathbf{c}$.

(b) Conjugating by the translation $t_{-\mathbf{c}}$ gives an injective homomorphism $G \to \mathrm{E}(n)$, $f \mapsto t_{-\mathbf{c}} \circ f \circ t_{\mathbf{c}}$, whose image consists of motions fixing $\mathbf{0}$, hence of linear ones by Theorem 21.4.1; those are the orthogonal maps. So G is isomorphic to a subgroup of $\mathrm{O}(n)$, namely $\{\lambda(f) : f \in G\}$ in the notation of Proposition 21.4.3. If $t_{\mathbf{b}} \in G$ then $t_{\mathbf{b}}(\mathbf{c}) = \mathbf{c}$ by (a), so $\mathbf{b} = \mathbf{0}$. Geometrically: a finite figure cannot be carried onto itself by a non-trivial translation, because a translation would move its centroid.

21.5 Affine and Euclidean Quadrics

Chapter 13 classified quadratic forms up to congruence, and the answer over $\mathbb{R}$ was the inertia. A curve like $5x^2 + 4xy + 5y^2 - 14x - 14y - 7 = 0$ is not a quadratic form, though: it has linear terms and a constant, and its zero set does not pass through the origin. This section asks what the inertia classification becomes once the origin is given up, which is exactly the question affine geometry was built for. Two answers come out, one for affine changes of coordinates and one for the rigid motions of Definition 21.4.1, and the difference between them is the difference between "it is an ellipse" and "its semi-axes are $\sqrt{7}$ and $\sqrt{3}$".

21.5.1 Where characteristic two bites

Everything in this section needs a field in which $2 \neq 0$, and it is worth seeing why before any definition is written down.

A degree-two polynomial in $x_1, \dots, x_n$ has a homogeneous quadratic part, and we want to write that part as $\mathbf{x}^{\top}\mathbf{A}\mathbf{x}$ with $\mathbf{A}$ **symmetric**, so that Chapter 13 applies to it. For a symmetric $\mathbf{A}$ the coefficient of $x_i x_j$ with $i \neq j$ is $a_{ij} + a_{ji} = 2a_{ij}$. Recovering a_{ij} from the polynomial means halving, which is the division by $1 + 1$ that Theorem 13.3.5 performs, and on which the uniqueness of the symmetric matrix attached to a quadratic form (Definition 13.3.2) depends.

Over $\mathbb{F}_2$ the halving is not merely inconvenient; the target is not there. Every symmetric $\mathbf{A} \in M_n(\mathbb{F}_2)$ gives

$$\mathbf{x}^{\top}\mathbf{A}\mathbf{x} = \sum_i a_{ii}x_i^2 + 2\sum_{i<j} a_{ij}x_i x_j = \sum_i a_{ii}x_i^2,$$

and since $a^2 = a$ for $a \in \mathbb{F}_2$ and squaring is additive there, this is $\big(\sum_i a_{ii}x_i\big)^2$, the square of a **linear** form. So over $\mathbb{F}_2$ no expression $\mathbf{x}^{\top}\mathbf{A}\mathbf{x}$ with $\mathbf{A}$ symmetric ever has an xy term, the

polynomial xy is not of that shape at all, and the ones that are have already collapsed to squares of linear forms. There is nothing left to classify.

So: throughout this section F is a field with $\operatorname{char} F \neq 2$ (Definition 0.7.2), and from the affine classification onward $F = \mathbb{R}$. The hypothesis will be invoked by name at each of the three places where it does work: writing the linear part as $2\mathbf{b}^{\top}\mathbf{x}$, reading off a symmetric $\mathbf{A}$, and solving for a center.

21.5.2 The equation of a quadric

Fix an origin O and a basis of the direction space, which by Proposition 21.1.3 identifies the affine space $\mathcal{A}$ of dimension n with F^n. Every polynomial of degree 2 in the resulting coordinates can then be written in one standard shape.

A quadric is what you get when a quadratic form is allowed to forget where the origin is.

Definition 21.5.1 — Quadric

Let $\operatorname{char} F \neq 2$ and let $\mathcal{A}$ be an affine space of dimension n over F, identified with F^n by a choice of origin and basis (Proposition 21.1.3). A **quadric polynomial** on $\mathcal{A}$ is a function

$$Q(\mathbf{x}) = \mathbf{x}^{\top}\mathbf{A}\mathbf{x} + 2\mathbf{b}^{\top}\mathbf{x} + c$$

with $\mathbf{A} \in M_n(F)$ **symmetric and non-zero**, $\mathbf{b} \in F^n$ and $c \in F$. Its **quadratic part** is the quadratic form $q(\mathbf{x}) = \mathbf{x}^{\top}\mathbf{A}\mathbf{x}$. The **quadric** defined by Q is its zero set

$$\{\, \mathbf{x} \in F^n : Q(\mathbf{x}) = 0 \,\}.$$

For $n = 2$ a quadric is called a **conic**.

Read the clauses. "**Symmetric**" is a normalization, not a restriction: $\mathbf{x}^{\top}\mathbf{A}\mathbf{x} = \mathbf{x}^{\top}\mathbf{A}^{\top}\mathbf{x}$ because a 1×1 matrix equals its transpose, so $\mathbf{A}$ may always be replaced by $\frac{1}{2}(\mathbf{A} + \mathbf{A}^{\top})$, and once symmetric it is determined by q (Theorem 13.3.5). "**Non-zero**" excludes $\mathbf{A} = \mathbf{0}$, where Q would be affine and its zero set a flat (Definition 21.2.1) already handled in Section 2; it is the clause that makes the object genuinely quadratic. The factor 2 in $2\mathbf{b}^{\top}\mathbf{x}$ is a convention we may adopt because 2 is invertible: a linear part $\beta_1 x_1 + \cdots + \beta_n x_n$ is $2\mathbf{b}^{\top}\mathbf{x}$ with $b_i = \beta_i/2$. It pays for itself in every formula below.

The data are recoverable from the function. Definition 21.5.1 calls Q a function, so before speaking of "its" quadratic part or "its" constant we must check that $\mathbf{A}$, $\mathbf{b}$ and c are determined by Q. They are, over any field of characteristic $\neq 2$. First $Q(\mathbf{0}) = c$. Next

$$Q(\mathbf{x}) - Q(-\mathbf{x}) = 4\mathbf{b}^{\top}\mathbf{x} \qquad \text{for every } \mathbf{x} \in F^n,$$

and $4 = 2 \cdot 2 \neq 0$, so taking $\mathbf{x} = \mathbf{e}_i$ recovers b_i for each i. Finally $\mathbf{x}^{\top}\mathbf{A}\mathbf{x} = Q(\mathbf{x}) - 2\mathbf{b}^{\top}\mathbf{x} - c$ is then determined as a function of $\mathbf{x}$, and a **symmetric** $\mathbf{A}$ is determined by that quadratic form (Theorem 13.3.5). So the triple $(\mathbf{A}, \mathbf{b}, c)$ is unique.

Examples. Over $\mathbb{R}$ with $n = 2$:

- $x^2 + y^2 - 1$, with $\mathbf{A} = \mathbf{I}_2$, $\mathbf{b} = \mathbf{0}$, $c = -1$: the unit circle.
- $x^2 - y$, with $\mathbf{A} = \operatorname{diag}(1, 0)$, $\mathbf{b} = (0, -\frac{1}{2})$, $c = 0$: a parabola. Here the halving convention is visible, and $\mathbf{A}$ is singular.

- $x^2 + y^2$: the zero set is the single point $\mathbf{0}$, although the polynomial has degree 2.
- x^2: the zero set is the line $x = 0$, traced "twice" in the sense that $\mathbf{A} = \operatorname{diag}(1, 0)$ has rank 1 and the polynomial is a square. This is the degenerate case, and it matters because the classification must find room for it.
- $x^2 + y^2 + 1$: the zero set is **empty**. Over $\mathbb{R}$ a quadric may have no points at all, and the classification below has two different normal forms whose zero sets are both empty.

Non-example by minimal change. Replace $x^2 + y^2 - 1$ by $x^4 + y^2 - 1$: the quadratic part is no longer a quadratic form, and there is no $\mathbf{A}$. Replace it instead by $2x + 3y - 1$: now $\mathbf{A} = \mathbf{0}$, the clause "non-zero" fails, and the zero set is a line, not a quadric.

> *Warning.* **A quadric is classified through its polynomial, not through its point set.** Over $\mathbb{R}$ the polynomials $x^2 + y^2 + 1$ and $x^2 + 1$ both have empty zero set, and no coordinate change can be expected to tell empty from empty; yet the two polynomials will land in different classes below, and rightly so, because their behavior over $\mathbb{C}$ and their intersections with lines differ. Everything in the affine classification below is a statement about the polynomial Q up to an invertible affine substitution and a non-zero scalar factor. When the zero set determines Q up to a scalar it will be said explicitly.

21.5.3 The matrix of a quadric

The whole point of writing the linear part as $2\mathbf{b}^\top\mathbf{x}$ is that Q then becomes a single quadratic form in one extra variable. Write

$$\tilde{\mathbf{x}} = \begin{pmatrix} \mathbf{x} \\ 1 \end{pmatrix} \in F^{n+1}, \qquad \widetilde{\mathbf{A}} = \begin{pmatrix} \mathbf{A} & \mathbf{b} \\ \mathbf{b}^\top & c \end{pmatrix} \in M_{n+1}(F),$$

so that $\widetilde{\mathbf{A}}$ is symmetric and

$$\tilde{\mathbf{x}}^\top \widetilde{\mathbf{A}}\, \tilde{\mathbf{x}} = \mathbf{x}^\top \mathbf{A}\mathbf{x} + \mathbf{x}^\top \mathbf{b} + \mathbf{b}^\top \mathbf{x} + c = Q(\mathbf{x}),$$

the two middle terms being equal because each is a 1×1 matrix and one is the transpose of the other. We call $\widetilde{\mathbf{A}}$ the **big matrix** of Q and $\mathbf{A}$ its **small matrix**. The extra coordinate is the same trick that turned an affine map into an $(n+1) \times (n+1)$ block matrix in Proposition 21.1.7, and the two devices fit together exactly.

Proposition 21.5.1 — Affine Substitution Is Congruence of the Big Matrix

Let Q have big matrix $\widetilde{\mathbf{A}}$, let $\mathbf{M} \in M_n(F)$ be invertible, let $\mathbf{t} \in F^n$, and let $g(\mathbf{y}) = \mathbf{M}\mathbf{y} + \mathbf{t}$ be the corresponding invertible affine map (Definition 21.1.3), with block matrix (Proposition 21.1.7)

$$\widehat{g} = \begin{pmatrix} \mathbf{M} & \mathbf{t} \\ \mathbf{0}^\top & 1 \end{pmatrix}.$$

Then $Q \circ g$ is again a quadric polynomial, its big matrix is $\widehat{g}^\top \widetilde{\mathbf{A}} \widehat{g}$, and its small matrix, linear vector and constant are

$$\mathbf{A}' = \mathbf{M}^\top \mathbf{A}\mathbf{M}, \qquad \mathbf{b}' = \mathbf{M}^\top(\mathbf{A}\mathbf{t} + \mathbf{b}), \qquad c' = Q(\mathbf{t}).$$

Proof. By Proposition 21.1.7, $\widehat{g}\,\tilde{\mathbf{y}} = \big(\mathbf{M}\mathbf{y} + \mathbf{t},\, 1\big) = \widetilde{g(\mathbf{y})}$. Hence

$$Q(g(\mathbf{y})) = \widetilde{g(\mathbf{y})}^{\top}\,\widetilde{\mathbf{A}}\,\widetilde{g(\mathbf{y})} = \tilde{\mathbf{y}}^{\top}\big(\widehat{g}^{\top}\widetilde{\mathbf{A}}\widehat{g}\big)\tilde{\mathbf{y}},$$

and $\widehat{g}^{\top}\widetilde{\mathbf{A}}\widehat{g}$ is symmetric, being a congruence of a symmetric matrix (Proposition 13.2.4). Multiplying the blocks out,

$$\begin{aligned}\begin{pmatrix}\mathbf{M}^{\top} & \mathbf{0}\\ \mathbf{t}^{\top} & 1\end{pmatrix}\begin{pmatrix}\mathbf{A} & \mathbf{b}\\ \mathbf{b}^{\top} & c\end{pmatrix}\begin{pmatrix}\mathbf{M} & \mathbf{t}\\ \mathbf{0}^{\top} & 1\end{pmatrix} &= \begin{pmatrix}\mathbf{M}^{\top}\mathbf{A} & \mathbf{M}^{\top}\mathbf{b}\\ \mathbf{t}^{\top}\mathbf{A}+\mathbf{b}^{\top} & \mathbf{t}^{\top}\mathbf{b}+c\end{pmatrix}\begin{pmatrix}\mathbf{M} & \mathbf{t}\\ \mathbf{0}^{\top} & 1\end{pmatrix}\\ &= \begin{pmatrix}\mathbf{M}^{\top}\mathbf{A}\mathbf{M} & \mathbf{M}^{\top}(\mathbf{A}\mathbf{t}+\mathbf{b})\\ (\mathbf{A}\mathbf{t}+\mathbf{b})^{\top}\mathbf{M} & \mathbf{t}^{\top}\mathbf{A}\mathbf{t}+2\mathbf{b}^{\top}\mathbf{t}+c\end{pmatrix},\end{aligned}$$

where the bottom-left block was transposed using $\mathbf{A}^{\top} = \mathbf{A}$. Reading off the blocks gives $\mathbf{A}'$, $\mathbf{b}'$ and $c' = \mathbf{t}^{\top}\mathbf{A}\mathbf{t} + 2\mathbf{b}^{\top}\mathbf{t} + c = Q(\mathbf{t})$. Finally $\mathbf{A}' = \mathbf{M}^{\top}\mathbf{A}\mathbf{M}$ is non-zero, since $\mathbf{M}$ is invertible and congruence preserves rank (Theorem 13.2.3), so $Q \circ g$ is a quadric polynomial. This proves the proposition. ∎

Three consequences are worth naming at once. The new constant is Q evaluated at the new origin — obvious in hindsight, since $\mathbf{y} = \mathbf{0}$ means $\mathbf{x} = \mathbf{t}$. The new small matrix is a congruence of the old one, so **the rank of $\mathbf{A}$ is an affine invariant of Q** by Theorem 13.2.3, and over $\mathbb{R}$ **so is its inertia** by Corollary 13.5.2 (b) — the latter only up to the simultaneous exchange of n_+ with n_- that a negative scalar factor forces, as Step 4 of the classification theorem below records. And $\widetilde{\mathbf{A}}$ itself only undergoes congruences by matrices whose last row is $(\mathbf{0}^{\top}, 1)$, which is a strictly smaller set than all congruences: that restriction is exactly why the affine classification is finer than Chapter 13's.

Replacing Q by λQ with $\lambda \neq 0$ does not change the zero set and replaces $\widetilde{\mathbf{A}}$ by $\lambda\widetilde{\mathbf{A}}$, so a scalar factor costs nothing geometrically and is worth allowing alongside the substitution.

Definition 21.5.2 — Affine Equivalence of Quadric Polynomials

Two quadric polynomials Q_1, Q_2 on F^n are **affinely equivalent** when

$$Q_2 = \lambda\,(Q_1 \circ g)$$

for some invertible affine map g (Definition 21.1.3) and some $\lambda \in F$ with $\lambda \neq 0$.

This is an equivalence relation, because the invertible affine maps form a group and the non-zero scalars do too.

21.5.4 Centers

A circle has a center and a parabola does not, and the difference is visible in the equation before any picture is drawn.

A center is a point about which the equation is symmetric.

Definition 21.5.3 — Center of a Quadric

Let Q be a quadric polynomial on F^n. A point $\mathbf{p} \in F^n$ is a **center** of Q if

$$Q(\mathbf{p}+\mathbf{v}) = Q(\mathbf{p}-\mathbf{v}) \qquad \text{for every } \mathbf{v} \in F^n.$$

Q is **central** if it has at least one center, and **centerless** otherwise.

In words: reflecting in $\mathbf{p}$, the map $\mathbf{p}+\mathbf{v} \mapsto \mathbf{p}-\mathbf{v}$, carries the quadric to itself, and more than that, leaves the whole polynomial unchanged. The next proposition turns this into a linear system.

Proposition 21.5.2 — When a Center Exists

Let $\operatorname{char} F \neq 2$ and let $Q(\mathbf{x}) = \mathbf{x}^\top \mathbf{A}\mathbf{x} + 2\mathbf{b}^\top \mathbf{x} + c$ be a quadric polynomial on F^n. Then:

(a) $\mathbf{p}$ is a center of Q if and only if $\mathbf{A}\mathbf{p} + \mathbf{b} = \mathbf{0}$;

(b) Q is central if and only if $\mathbf{b} \in \operatorname{col}(\mathbf{A})$; in particular Q is central whenever $\mathbf{A}$ is invertible, and the center is then the unique point $-\mathbf{A}^{-1}\mathbf{b}$;

(c) if $\mathbf{p}$ is a center then $Q(\mathbf{p}+\mathbf{v}) = Q(\mathbf{p}) + \mathbf{v}^\top \mathbf{A}\mathbf{v}$ for every $\mathbf{v}$, and the value $Q(\mathbf{p})$ is the same at every center.

Idea. Expand $Q(\mathbf{p} \pm \mathbf{v})$ and subtract. Everything even in $\mathbf{v}$ cancels and what is left is $4\mathbf{v}^\top(\mathbf{A}\mathbf{p} + \mathbf{b})$, a linear functional of $\mathbf{v}$. A linear functional vanishes identically exactly when its vector vanishes, so the condition on $\mathbf{p}$ is one linear equation per coordinate. The 4 is where $\operatorname{char} F \neq 2$ is spent.

Proof.

(a) Expanding and using $\mathbf{A}^\top = \mathbf{A}$, so that $\mathbf{p}^\top \mathbf{A}\mathbf{v} = \mathbf{v}^\top \mathbf{A}\mathbf{p}$,

$$Q(\mathbf{p} \pm \mathbf{v}) = \mathbf{p}^\top \mathbf{A}\mathbf{p} \pm 2\mathbf{v}^\top \mathbf{A}\mathbf{p} + \mathbf{v}^\top \mathbf{A}\mathbf{v} + 2\mathbf{b}^\top \mathbf{p} \pm 2\mathbf{b}^\top \mathbf{v} + c.$$

Subtracting the two,

$$Q(\mathbf{p}+\mathbf{v}) - Q(\mathbf{p}-\mathbf{v}) = 4\mathbf{v}^\top \mathbf{A}\mathbf{p} + 4\mathbf{b}^\top \mathbf{v} = 4\,\mathbf{v}^\top(\mathbf{A}\mathbf{p} + \mathbf{b}). \tag{21.5.1}$$

Since $\operatorname{char} F \neq 2$, the element $4 = 2 \cdot 2$ is non-zero. So $\mathbf{p}$ is a center exactly when $\mathbf{v}^\top(\mathbf{A}\mathbf{p} + \mathbf{b}) = 0$ for every $\mathbf{v}$. Taking $\mathbf{v} = \mathbf{e}_i$ shows that this forces every entry of $\mathbf{A}\mathbf{p} + \mathbf{b}$ to vanish; conversely $\mathbf{A}\mathbf{p} + \mathbf{b} = \mathbf{0}$ makes Eq. 21.5.1 zero for every $\mathbf{v}$. Hence (a).

(b) By (a), a center is a solution of $\mathbf{A}\mathbf{p} = -\mathbf{b}$, and such a solution exists exactly when $-\mathbf{b}$, equivalently $\mathbf{b}$, lies in $\operatorname{col}(\mathbf{A})$ (Theorem 0.9.3). If $\mathbf{A}$ is invertible then $\operatorname{col}(\mathbf{A}) = F^n$ and $\mathbf{p} = -\mathbf{A}^{-1}\mathbf{b}$ is the only solution.

(c) With $\mathbf{A}\mathbf{p} + \mathbf{b} = \mathbf{0}$, the expansion above with the sign $+$ reads

$$Q(\mathbf{p}+\mathbf{v}) = \big(\mathbf{p}^\top \mathbf{A}\mathbf{p} + 2\mathbf{b}^\top \mathbf{p} + c\big) + 2\mathbf{v}^\top(\mathbf{A}\mathbf{p} + \mathbf{b}) + \mathbf{v}^\top \mathbf{A}\mathbf{v} = Q(\mathbf{p}) + \mathbf{v}^\top \mathbf{A}\mathbf{v}.$$

If $\mathbf{p}'$ is a second center then $\mathbf{A}(\mathbf{p}' - \mathbf{p}) = (-\mathbf{b}) - (-\mathbf{b}) = \mathbf{0}$, so putting $\mathbf{v} = \mathbf{p}' - \mathbf{p}$ in

the last identity gives $Q(\mathbf{p}') = Q(\mathbf{p}) + \mathbf{v}^\top \mathbf{A}\mathbf{v} = Q(\mathbf{p}) + \mathbf{v}^\top \mathbf{0} = Q(\mathbf{p})$. This proves the proposition.

■

Part (c) is the useful half. Translating the origin to a center — that is, applying Proposition 21.5.1 with $\mathbf{M} = \mathbf{I}$ and $\mathbf{t} = \mathbf{p}$ — gives $\mathbf{b}' = \mathbf{A}\mathbf{p} + \mathbf{b} = \mathbf{0}$, so the equation becomes $\mathbf{v}^\top \mathbf{A}\mathbf{v} + Q(\mathbf{p}) = 0$ with no linear term at all, and Chapter 13 applies verbatim. That single move is the engine of the classification.

Example. (The parabola is centerless)

Show that $Q(x, y) = x^2 - y$ over $\mathbb{R}$ has no center, and find all centers of $Q_1(x, y) = x^2 - 1$.

Solution. For Q, $\mathbf{A} = \operatorname{diag}(1, 0)$ and $\mathbf{b} = (0, -\frac{1}{2})$. Then $\operatorname{col}(\mathbf{A}) = \operatorname{span}(\mathbf{e}_1)$ and $\mathbf{b} \notin \operatorname{col}(\mathbf{A})$ because its second entry is non-zero, so by Proposition 21.5.2 (b) there is no center. Concretely, $Q(\mathbf{p} + \mathbf{v}) - Q(\mathbf{p} - \mathbf{v}) = 4\mathbf{v}^\top(\mathbf{A}\mathbf{p} + \mathbf{b}) = 4(v_1 p_1 - \frac{1}{2} v_2)$, which is $-2 \neq 0$ at $\mathbf{v} = \mathbf{e}_2$ whatever $\mathbf{p}$ is.

For Q_1, $\mathbf{A} = \operatorname{diag}(1, 0)$ and $\mathbf{b} = \mathbf{0} \in \operatorname{col}(\mathbf{A})$, so the centers are the solutions of $\mathbf{A}\mathbf{p} = \mathbf{0}$, namely the whole y-axis. That is right: Q_1 defines the pair of lines $x = \pm 1$, and reflecting in any point of the y-axis swaps them. And $Q_1(\mathbf{p}) = -1$ at every one of those centers, as Proposition 21.5.2 (c) promises.

Quick check. A quadric polynomial on F^n with $\operatorname{rank} \mathbf{A} = n$ has exactly one center, and one with $\operatorname{rank} \mathbf{A} = n - 1$ has either none or a whole line of them. Which is it for $x^2 + y^2 - 2x$ on $\mathbb{R}^2$, and which for $x^2 + 2y$?

Solution. For $x^2 + y^2 - 2x$ we have $\mathbf{A} = \mathbf{I}_2$ of rank 2 and $\mathbf{b} = (-1, 0)$, so the unique center is $-\mathbf{A}^{-1}\mathbf{b} = (1, 0)$; indeed the curve is the circle $(x-1)^2 + y^2 = 1$. For $x^2 + 2y$ we have $\mathbf{A} = \operatorname{diag}(1, 0)$ of rank 1 and $\mathbf{b} = (0, 1) \notin \operatorname{col}(\mathbf{A}) = \operatorname{span}(\mathbf{e}_1)$, so there is no center at all: it is a parabola. The line of centers occurs instead for $x^2 - 1$, where $\mathbf{b} = \mathbf{0}$ does lie in $\operatorname{col}(\mathbf{A})$.

21.5.5 The affine classification over the reals

Now the theorem. Over $\mathbb{R}$ we may diagonalize the small matrix by Sylvester (Corollary 13.5.2), translate to kill as much of the linear part as a center allows, and then scale. What survives is a short list.

Theorem 21.5.3 — Affine Classification of Real Quadrics

Let $Q(\mathbf{x}) = \mathbf{x}^\top \mathbf{A}\mathbf{x} + 2\mathbf{b}^\top \mathbf{x} + c$ be a quadric polynomial on $\mathbb{R}^n$ and let $r = \operatorname{rank} \mathbf{A}$, which is ≥ 1 because $\mathbf{A} \neq \mathbf{0}$ (Definition 21.5.1). Then Q is affinely equivalent to **exactly one** polynomial from the following list, for one value of p in the range shown, where $\sigma_{r,p}(\mathbf{y}) = y_1^2 + \cdots + y_p^2 - y_{p+1}^2 - \cdots - y_r^2$:

(I) $\sigma_{r,p}(\mathbf{y}) - 1$, with $0 \leq p \leq r$;

(II) $\sigma_{r,p}(\mathbf{y})$, with $r \le 2p \le 2r$;
(III) $\sigma_{r,p}(\mathbf{y}) - y_{r+1}$, with $r < n$ and $r \le 2p \le 2r$.

Case (III) occurs exactly when Q is centerless. The parameter p that occurs is $n_+(\mathbf{A})$ or $n_-(\mathbf{A})$, the two being interchanged by a negative scalar factor (Definition 13.5.1).

Idea. Three moves, in this order, and each is a result already proved.

① **Diagonalize the quadratic part.** Sylvester's law (Corollary 13.5.2) produces coordinates in which the quadratic part is $\sigma_{r,p}$; by Proposition 21.5.1 this changes $\mathbf{b}$ and c but nothing else.

② **Complete the square in the first r variables.** A translation kills the linear coefficients $b_1, \dots, b_r$, because those are exactly the coordinates in which $\mathbf{A}$ is invertible. This is Proposition 21.5.2 read one coordinate at a time.

③ **Deal with what is left,** a polynomial $\sigma_{r,p} + 2\sum_{i>r} b_i y_i + c$ in which the y_i with $i > r$ appear only linearly. If they do not appear at all, scaling clears the constant to 0 or -1, giving (II) or (I). If one of them does appear, it can be used as a new coordinate that swallows the constant too, giving (III).

That the list has no repetitions is a separate, purely computational matter: the pair (inertia of $\mathbf{A}$, inertia of $\widetilde{\mathbf{A}}$) is an affine invariant by Proposition 21.5.1, and reading it off the three families separates them.

Proof. **Step 1: diagonalize.** Write $(p, r-p, n-r)$ for the inertia of $\mathbf{A}$ (Definition 13.5.1); this p is the one carried through Steps 1 to 3. By Corollary 13.5.2 (a) there is an invertible $\mathbf{M}_1$ with $\mathbf{M}_1^\top \mathbf{A} \mathbf{M}_1 = \mathbf{D}$, where $\mathbf{D} = \operatorname{diag}(\epsilon_1, \dots, \epsilon_n)$ has $\epsilon_i = 1$ for $i \le p$, $\epsilon_i = -1$ for $p < i \le r$ and $\epsilon_i = 0$ for $i > r$. Substituting $\mathbf{x} = \mathbf{M}_1 \mathbf{y}$ and applying Proposition 21.5.1 with $\mathbf{t} = \mathbf{0}$, the polynomial becomes

$$Q_1(\mathbf{y}) = \sigma_{r,p}(\mathbf{y}) + 2\mathbf{b}_1^\top \mathbf{y} + c, \qquad \mathbf{b}_1 = \mathbf{M}_1^\top \mathbf{b}.$$

Step 2: complete the square. Let $\mathbf{t}$ have entries $t_i = -\epsilon_i b_{1,i}$ for $i \le r$ and $t_i = 0$ for $i > r$, and substitute $\mathbf{y} = \mathbf{z} + \mathbf{t}$. By Proposition 21.5.1 with $\mathbf{M} = \mathbf{I}$, the new linear vector is $\mathbf{b}_2 = \mathbf{D}\mathbf{t} + \mathbf{b}_1$, whose i-th entry for $i \le r$ is $\epsilon_i t_i + b_{1,i} = -\epsilon_i^2 b_{1,i} + b_{1,i} = 0$, since $\epsilon_i^2 = 1$ there; for $i > r$ it is $b_{1,i}$, unchanged. The new constant is $c_2 = Q_1(\mathbf{t})$. So

$$Q_2(\mathbf{z}) = \sigma_{r,p}(\mathbf{z}) + 2\sum_{i>r} b_{1,i} z_i + c_2.$$

Step 3, Case A: $b_{1,i} = 0$ for every $i > r$. Then $Q_2 = \sigma_{r,p} + c_2$.

If $c_2 = 0$, this is $\sigma_{r,p}$. If $r \le 2p$ we are in case (II). Otherwise multiply by $\lambda = -1$ and reverse the order of the first r coordinates, which turns $\sigma_{r,p}$ into $\sigma_{r,\,r-p}$ with $r \le 2(r-p)$; again case (II).

If $c_2 \neq 0$, substitute $z_i = |c_2|^{1/2} w_i$ for $i \le r$ and $z_i = w_i$ otherwise, an invertible linear change, and then multiply by $\lambda = 1/|c_2|$. The result is $\sigma_{r,p}(\mathbf{w}) + \operatorname{sgn}(c_2)$. If $\operatorname{sgn}(c_2) = -1$ this is case (I) with parameter p. If $\operatorname{sgn}(c_2) = +1$, multiply by -1 and reverse the order of the first r coordinates to get $\sigma_{r,\,r-p} - 1$, case (I) with parameter $r - p$.

Step 3, Case B: $b_{1,i} \neq 0$ for some $i > r$. Here $r < n$. Put $\mathbf{c} = (b_{1,r+1}, \dots, b_{1,n}) \neq \mathbf{0}$ in $\mathbb{R}^{n-r}$. Extend $2\mathbf{c}$ to a basis of $\mathbb{R}^{n-r}$ (Theorem 1.6.5) and let $\mathbf{N} \in M_{n-r}(\mathbb{R})$ be the invertible matrix whose **first row** is $2\mathbf{c}^{\top}$ and whose remaining rows complete it to an invertible matrix; such rows exist because a basis of $\mathbb{R}^{n-r}$ written as rows forms an invertible matrix. Define new coordinates by

$$u_i = z_i \ (i \leq r), \qquad (u_{r+1}, \dots, u_n)^{\top} = \mathbf{N}(z_{r+1}, \dots, z_n)^{\top} + c_2\, \mathbf{e}_1,$$

an invertible affine substitution, under which $u_{r+1} = 2\mathbf{c}^{\top}(z_{r+1}, \dots, z_n) + c_2$. Hence $Q_2 = \sigma_{r,p}(\mathbf{u}) + u_{r+1}$. Replacing u_{r+1} by $-y_{r+1}$ and keeping the other coordinates gives $\sigma_{r,p}(\mathbf{y}) - y_{r+1}$. If $r > 2p$, multiply by -1, reverse the order of the first r coordinates and replace y_{r+1} by $-y_{r+1}$; the result is $\sigma_{r,\,r-p}(\mathbf{y}) - y_{r+1}$ with $r \leq 2(r-p)$. Either way we reach case (III).

Step 4: the list has no repetitions. By Proposition 21.5.1 an affine equivalence replaces $\mathbf{A}$ by $\lambda \mathbf{M}^{\top}\mathbf{A}\mathbf{M}$ and $\widetilde{\mathbf{A}}$ by $\lambda \widehat{g}^{\top}\widetilde{\mathbf{A}}\widehat{g}$, with $\mathbf{M}$ and $\widehat{g}$ invertible. A congruence preserves inertia (Corollary 13.5.2 (b)), and multiplying a real symmetric matrix by λ leaves the inertia alone if $\lambda > 0$ and exchanges n_+ with n_- if $\lambda < 0$. Hence the **invariant pair**

$$\begin{aligned} &\big(\operatorname{In}\mathbf{A},\ \operatorname{In}\widetilde{\mathbf{A}}\big),\\ &\quad \text{taken up to exchanging } n_+ \text{ with } n_-\\ &\quad \text{in both entries simultaneously,} \end{aligned}$$

in which In is the inertia triple of Definition 16.10.1, is an invariant of the affine equivalence class. Write $\mathbf{D}_{r,p} = \operatorname{diag}(\epsilon_1, \dots, \epsilon_n)$ for the small matrix shared by all three families. In family (I) the linear vector is $\mathbf{0}$ and the constant is -1, so $\widetilde{\mathbf{A}} = \mathbf{D}_{r,p} \oplus (-1)$; in family (II) the constant is 0, so $\widetilde{\mathbf{A}} = \mathbf{D}_{r,p} \oplus 0$. In family (III) the linear vector is $-\frac{1}{2}\mathbf{e}_{r+1}$ and the constant is 0, so $\widetilde{\mathbf{A}}$ is diagonal except in the four positions indexed by $r+1$ and $n+1$, where it carries the block $\begin{pmatrix} 0 & -\frac{1}{2} \\ -\frac{1}{2} & 0 \end{pmatrix}$, whose eigenvalues are $\frac{1}{2}$ and $-\frac{1}{2}$; the remaining diagonal entries are $\epsilon_1, \dots, \epsilon_r$ and $n-r-1$ zeros. So

$$\begin{aligned} \text{(I)}: &\quad \operatorname{In}\mathbf{A} = (p,\, r-p,\, n-r), \quad \operatorname{In}\widetilde{\mathbf{A}} = (p,\, r-p+1,\, n-r);\\ \text{(II)}: &\quad \operatorname{In}\mathbf{A} = (p,\, r-p,\, n-r), \quad \operatorname{In}\widetilde{\mathbf{A}} = (p,\, r-p,\, n-r+1);\\ \text{(III)}: &\quad \operatorname{In}\mathbf{A} = (p,\, r-p,\, n-r), \quad \operatorname{In}\widetilde{\mathbf{A}} = (p+1,\, r-p+1,\, n-r-1). \end{aligned}$$

Therefore $\operatorname{rank}\mathbf{A} = r$ in all three, while $\operatorname{rank}\widetilde{\mathbf{A}}$ is $r+1$, r and $r+2$ respectively. Ranks are unaffected by the exchange of n_+ and n_-, so the pair $(\operatorname{rank}\mathbf{A}, \operatorname{rank}\widetilde{\mathbf{A}})$ already determines both the family and r.

It remains to separate two members of one family with the same r. If the invariants agree without the exchange, then $\operatorname{In}\mathbf{A}$ gives $p = p'$ at once. Suppose instead they agree after the exchange, so that $p' = r - p$.

Family (I). The exchanged $\operatorname{In}\widetilde{\mathbf{A}}$ of the p-member is $(r-p+1,\, p,\, n-r)$, while the p'-member has $(p',\, r-p'+1,\, n-r) = (r-p,\, p+1,\, n-r)$. Comparing first entries gives $r-p+1 = r-p$, which is false. So family (I) has no repetitions.

Families (II) and (III). Here both members satisfy $r \leq 2p$ and $r \leq 2p' = 2(r-p)$, that is $2p \leq r$. Hence $2p = r = 2p'$ and $p = p'$.

So distinct entries of the list are affinely inequivalent, and Step 3 showed every Q meets one. The normal form reached has small matrix $\mathbf{D}_{r,p}$, of inertia $(p,\, r-p,\, n-r)$; since $\operatorname{In}\mathbf{A}$ is preserved by affine equivalence up to the exchange of n_+ with n_-, that p is $n_+(\mathbf{A})$ or $n_-(\mathbf{A})$, as claimed. Finally, Q is centerless exactly in case (III): by Proposition 21.5.2 (b) centrality is the condition $\mathbf{b} \in \operatorname{col}(\mathbf{A})$, which is preserved by affine equivalence because centers are (if $\mathbf{p}$ is a center of Q and g is invertible affine, then $g^{-1}(\mathbf{p})$ is a center of $\lambda\, Q \circ g$, since $\mathbf{v} \mapsto \mathbf{M}\mathbf{v}$ is a bijection of $\mathbb{R}^n$); and $\mathbf{0}$ is a center in cases (I) and (II), while in case (III) the small matrix is $\mathbf{D}_{r,p}$ and the linear vector is $-\frac{1}{2}\mathbf{e}_{r+1} \notin \operatorname{col}(\mathbf{D}_{r,p}) = \operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_r)$. This proves the theorem.

■

21.5.5.1 The nine real conics

For $n = 2$ the parameters run over $r \in \{1, 2\}$ and $0 \le p \le r$, and the list has nine entries. Here they are, with the zero set of each. The last column records the classical names, and so does the paragraph on $n = 3$ below; those names are not defined anywhere in this book, and each set-theoretic reading is a one-line check from the normal form — for instance $x^2 + y^2 = -1$ has no real solution because a sum of squares is non-negative, and $x^2 - y^2 = 0$ is the pair of lines $y = \pm x$, by factoring.

Normal form	(r, p)	Family	$\operatorname{In}\mathbf{A}$	$\operatorname{In}\widetilde{\mathbf{A}}$	Zero set
$x^2 + y^2 = 1$	$(2, 2)$	I	$(2, 0, 0)$	$(2, 1, 0)$	ellipse
$x^2 - y^2 = 1$	$(2, 1)$	I	$(1, 1, 0)$	$(1, 2, 0)$	hyperbola
$x^2 + y^2 = -1$	$(2, 0)$	I	$(2, 0, 0)$	$(3, 0, 0)$	empty
$x^2 + y^2 = 0$	$(2, 2)$	II	$(2, 0, 0)$	$(2, 0, 1)$	one point
$x^2 - y^2 = 0$	$(2, 1)$	II	$(1, 1, 0)$	$(1, 1, 1)$	two crossing lines
$x^2 = 1$	$(1, 1)$	I	$(1, 0, 1)$	$(1, 1, 1)$	two parallel lines
$x^2 = -1$	$(1, 0)$	I	$(1, 0, 1)$	$(2, 0, 1)$	empty
$x^2 = 0$	$(1, 1)$	II	$(1, 0, 1)$	$(1, 0, 2)$	one line
$x^2 = y$	$(1, 1)$	III	$(1, 0, 1)$	$(2, 1, 0)$	parabola

Two rows of the table are written with the parameter p of the negated polynomial: $x^2 + y^2 = -1$ means $-x^2 - y^2 - 1 = 0$, which is $\sigma_{2,0} - 1$ after multiplying by -1, and likewise for $x^2 = -1$. Reading the two inertia columns up to a simultaneous exchange of the first two entries confirms that no two rows agree: rows 1, 3, 4 have $\operatorname{In}\mathbf{A} = (2, 0, 0)$ and differ in $\operatorname{In}\widetilde{\mathbf{A}}$; rows 2 and 5 differ in $\operatorname{In}\widetilde{\mathbf{A}}$; and rows 6, 7, 8, 9 have $\operatorname{In}\mathbf{A} = (1, 0, 1)$ with four different $\operatorname{In}\widetilde{\mathbf{A}}$. In each of those two groups the exchange changes $\operatorname{In}\mathbf{A}$, so it cannot rescue a match. The one group where $\operatorname{In}\mathbf{A}$ survives the exchange is rows 2 and 5, with $\operatorname{In}\mathbf{A} = (1, 1, 0)$; there $\operatorname{In}\widetilde{\mathbf{A}}$ is $(1, 2, 0)$ against $(1, 1, 1)$, and the exchanged forms $(2, 1, 0)$ and $(1, 1, 1)$ still disagree.

Rows 3 and 7 are the honest surprise: both zero sets are empty, and both are needed, because the polynomials are not affinely equivalent. Over $\mathbb{C}$ they are quite different objects. Row 7 is $x^2 + 1 = (x - i)(x + i)$, a pair of distinct lines, while row 3 has an invertible small matrix. Exercise (C2: Over another field) (a) below classifies affine quadrics over $\mathbb{C}$, where rank alone is the invariant and the two rows stay apart: row 3 has $\operatorname{rank}\mathbf{A} = 2$ and $\operatorname{rank}\widetilde{\mathbf{A}} = 3$, row 7 has 1 and 2. Read projectively, Section 10's rank criterion makes row 3 a smooth conic.

For $n = 3$ the same count gives $4 + 7 + 6 = 17$ normal forms. The new shapes are the ellipsoid $x^2 + y^2 + z^2 = 1$, the hyperboloids of one and two sheets $x^2 + y^2 - z^2 = \pm 1$, the cone $x^2 + y^2 - z^2 = 0$, the elliptic and hyperbolic paraboloids $x^2 \pm y^2 = z$, and the three cylinders $x^2 + y^2 = 1$, $x^2 - y^2 = 1$, $x^2 = y$, which are the conics of the table dragged along the missing coordinate. The rest are a pair of intersecting planes, a pair of parallel planes, a double plane, a line, a point and three empty sets.

> *Warning.* **The rank of $\widetilde{\mathbf{A}}$ does not classify; the inertia does.** The ellipse x^2+y^2-1, the hyperbola $x^2 - y^2 - 1$ and the empty conic $x^2 + y^2 + 1$ all have $\operatorname{rank} \mathbf{A} = 2$ and $\operatorname{rank} \widetilde{\mathbf{A}} = 3$. Their small matrices already differ in inertia in the hyperbola's case, and the ellipse and the empty conic are told apart only by $\operatorname{In} \widetilde{\mathbf{A}} = (2, 1, 0)$ against $(3, 0, 0)$. A count of non-zero eigenvalues cannot distinguish a curve from nothing at all.

21.5.6 Euclidean quadrics and principal axes

Affine equivalence forgets shape: every ellipse is affinely a circle. To keep shape, restrict the allowed substitutions to the Euclidean motions of $\mathbb{R}^n$, which by Theorem 21.4.1 are exactly the maps $\mathbf{x} = \mathbf{U}\mathbf{y} + \mathbf{t}$ with $\mathbf{U} \in \mathrm{O}(n)$; that theorem gives one direction, and the other is that such a map preserves distances, since $\mathbf{U}$ preserves norms (Theorem 10.7.3). Call two quadric polynomials **Euclidean equivalent** when one is $Q \circ g$ for such a g. Note that no scalar factor is allowed now, and that is deliberate: a scalar factor would rescale the lengths we are trying to measure.

The gain is immediate. Under $\mathbf{x} = \mathbf{U}\mathbf{y} + \mathbf{t}$ the small matrix becomes $\mathbf{U}^\top \mathbf{A} \mathbf{U}$, which is both a congruence and a **similarity**, since $\mathbf{U}^\top = \mathbf{U}^{-1}$. So the eigenvalues of $\mathbf{A}$, not merely their signs, are Euclidean invariants. This is the observation Chapter 11 made in Theorem 11.5.5, and the classification below is that theorem with the origin allowed to move.

Theorem 21.5.4 — Euclidean Classification of Real Quadrics

Let $Q(\mathbf{x}) = \mathbf{x}^\top \mathbf{A} \mathbf{x} + 2\mathbf{b}^\top \mathbf{x} + c$ be a quadric polynomial on $\mathbb{R}^n$, let $r = \operatorname{rank} \mathbf{A}$, and let $\lambda_1, \dots, \lambda_r$ be the non-zero eigenvalues of $\mathbf{A}$, listed with multiplicity. Then there is a Euclidean motion $\mathbf{x} = \mathbf{U}\mathbf{y} + \mathbf{t}$, with $\mathbf{U} \in \mathrm{O}(n)$, after which Q becomes exactly one of

(a) $\lambda_1 y_1^2 + \cdots + \lambda_r y_r^2 + c_0$, when Q is central, where $c_0 = Q(\mathbf{p})$ at any center $\mathbf{p}$;
(b) $\lambda_1 y_1^2 + \cdots + \lambda_r y_r^2 + 2\mu\, y_{r+1}$, when Q is centerless, where $\mu = \|\mathbf{b} - P_{\mathrm{col}(\mathbf{A})}\mathbf{b}\| > 0$.

The columns of $\mathbf{U}$ are an orthonormal basis of eigenvectors of $\mathbf{A}$, the first r of them for $\lambda_1, \dots, \lambda_r$; these are the **principal axes** of Q. The multiset $\{\lambda_1, \dots, \lambda_r\}$ and the number c_0, respectively μ, are unchanged by every Euclidean motion, so the normal form is unique up to the order of its terms.

> *Idea.* The spectral theorem replaces Step 1 of Theorem 21.5.3, and it is the only change: instead of scaling the eigenvalues away to ± 1 we keep them, because an orthogonal matrix is not allowed to rescale. Steps 2 and 3 then go through with one adjustment. In Step 3 we may no longer stretch a coordinate to absorb $\mathbf{c}$; instead we **rotate** the last $n - r$ coordinates so that $\mathbf{c}$ points along one of them, which is legitimate because those coordinates carry the eigenvalue 0 and a rotation among them leaves the quadratic part untouched.

Proof. **Step 1.** By Corollary 11.5.2 there is $\mathbf{U}_1 \in \mathrm{O}(n)$ with $\mathbf{U}_1^\top \mathbf{A}\mathbf{U}_1 = \mathbf{D} = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$, the eigenvalues of $\mathbf{A}$ with multiplicity, and we order the basis so that $\lambda_1, \dots, \lambda_r$ are the non-zero ones; the count is right because $\mathbf{D}$ is similar to $\mathbf{A}$, so $\operatorname{rank}\mathbf{D} = \operatorname{rank}\mathbf{A} = r$, and a diagonal matrix has rank equal to its number of non-zero entries. Substituting $\mathbf{x} = \mathbf{U}_1\mathbf{y}$ and using Proposition 21.5.1 with $\mathbf{t} = \mathbf{0}$ gives

$$Q_1(\mathbf{y}) = \sum_{i=1}^{r} \lambda_i y_i^2 + 2\mathbf{b}_1^\top \mathbf{y} + c, \qquad \mathbf{b}_1 = \mathbf{U}_1^\top \mathbf{b}.$$

Step 2. Translate by $\mathbf{t}_1$ with entries $-b_{1,i}/\lambda_i$ for $i \le r$ and 0 otherwise, which is legitimate because those λ_i are non-zero. As in Theorem 21.5.3, Step 2, the new linear vector has i-th entry $\lambda_i t_{1,i} + b_{1,i} = 0$ for $i \le r$ and $b_{1,i}$ for $i > r$. Write $\mathbf{c} = (b_{1,r+1}, \dots, b_{1,n})$ and c' for the new constant, so

$$Q_2(\mathbf{z}) = \sum_{i=1}^{r} \lambda_i z_i^2 + 2\mathbf{c}^\top (z_{r+1}, \dots, z_n) + c'.$$

Claim: $\mathbf{c} = \mathbf{0}$ *if and only if* Q *is central, and in general* $\|\mathbf{c}\| = \|\mathbf{b} - P_{\mathrm{col}(\mathbf{A})}\mathbf{b}\|$. The last $n - r$ columns $\mathbf{q}_{r+1}, \dots, \mathbf{q}_n$ of $\mathbf{U}_1$ are an orthonormal basis of the eigenspace of $\mathbf{A}$ for 0, that is of $\mathrm{nul}(\mathbf{A})$, and the entries of $\mathbf{c}$ are $\mathbf{q}_i^\top \mathbf{b} = \langle \mathbf{b}, \mathbf{q}_i \rangle$. By Theorem 10.6.5 (b) applied to the self-adjoint operator $\mathbf{x} \mapsto \mathbf{A}\mathbf{x}$, we have $\mathrm{col}(\mathbf{A}) = \mathrm{nul}(\mathbf{A})^\perp$, so by Theorem 10.3.2 the component of $\mathbf{b}$ in $\mathrm{nul}(\mathbf{A})$ is $\mathbf{b} - P_{\mathrm{col}(\mathbf{A})}\mathbf{b}$, and by Theorem 10.2.1 its norm is $\|\mathbf{c}\|$. Hence $\mathbf{c} = \mathbf{0}$ exactly when $\mathbf{b} \in \mathrm{col}(\mathbf{A})$, which is centrality by Proposition 21.5.2 (b). This proves the claim.

Step 3, central case. Here $\mathbf{c} = \mathbf{0}$, so $Q_2 = \sum_{i \le r} \lambda_i z_i^2 + c'$, which is form (a). The new origin $\mathbf{p}$ satisfies $\mathbf{A}\mathbf{p} + \mathbf{b} = \mathbf{0}$ by Proposition 21.5.2 (a), because the linear part has vanished, so $\mathbf{p}$ is a center and $c' = Q(\mathbf{p}) = c_0$ by Proposition 21.5.1; Proposition 21.5.2 (c) says the value does not depend on which center.

Step 3, centerless case. Here $\mathbf{c} \neq \mathbf{0}$. By Corollary 10.2.3 the unit vector $\mathbf{c}/\|\mathbf{c}\|$ extends to an orthonormal basis of $\mathbb{R}^{n-r}$; let $\mathbf{R} \in \mathrm{O}(n-r)$ have that basis as its columns, so $\mathbf{R}\mathbf{e}_1 = \mathbf{c}/\|\mathbf{c}\|$ and therefore $\mathbf{R}^\top \mathbf{c} = \|\mathbf{c}\|\,\mathbf{e}_1$. Put $\mathbf{U}_2 = \mathbf{I}_r \oplus \mathbf{R}$, which lies in $\mathrm{O}(n)$. Substituting $\mathbf{z} = \mathbf{U}_2\mathbf{w}$ leaves the quadratic part alone, since

$$\begin{aligned} \mathbf{U}_2^\top \big(\operatorname{diag}(\lambda_1, \dots, \lambda_r) \oplus \mathbf{0}\big)\mathbf{U}_2 &= \operatorname{diag}(\lambda_1, \dots, \lambda_r) \oplus \mathbf{R}^\top \mathbf{0} \mathbf{R} \\ &= \operatorname{diag}(\lambda_1, \dots, \lambda_r) \oplus \mathbf{0}, \end{aligned}$$

and turns the linear part into $2\mathbf{c}^\top \mathbf{R}(w_{r+1}, \dots, w_n)^\top = 2\|\mathbf{c}\| w_{r+1}$. Finally translate w_{r+1} by $-c'/(2\|\mathbf{c}\|)$, which changes no quadratic term because the coefficient of w_{r+1}^2 is $\lambda_{r+1} = 0$. The result is form (b) with $\mu = \|\mathbf{c}\| > 0$.

Step 4: invariance. Let $g(\mathbf{y}) = \mathbf{U}\mathbf{y} + \mathbf{t}$ with $\mathbf{U} \in \mathrm{O}(n)$. By Proposition 21.5.1, $Q \circ g$ has small matrix $\mathbf{U}^\top \mathbf{A}\mathbf{U}$, which is similar to $\mathbf{A}$ and so has the same eigenvalues with multiplicity (Theorem 6.10.3). Its linear vector is $\mathbf{b}' = \mathbf{U}^\top(\mathbf{A}\mathbf{t} + \mathbf{b})$. For the central case, $g^{-1}(\mathbf{p})$ is a center of $Q \circ g$ whenever $\mathbf{p}$ is a center of Q, as noted at the end of Theorem 21.5.3, and the value there is $(Q \circ g)(g^{-1}(\mathbf{p})) = Q(\mathbf{p})$; so c_0 is unchanged. For the centerless case, $\mathrm{nul}(\mathbf{U}^\top \mathbf{A}\mathbf{U}) = \mathbf{U}^\top \mathrm{nul}(\mathbf{A})$, and $\mathbf{A}\mathbf{t} \in \mathrm{col}(\mathbf{A}) = \mathrm{nul}(\mathbf{A})^\perp$, so the component of $\mathbf{b}'$ in $\mathrm{nul}(\mathbf{U}^\top \mathbf{A}\mathbf{U})$ is $\mathbf{U}^\top$ applied to the component of $\mathbf{b}$ in $\mathrm{nul}(\mathbf{A})$; an orthogonal matrix preserves norms (Theorem 10.7.3), so μ is unchanged. This proves the theorem.

■

When $\mathbf{A}$ is invertible and $c_0 \neq 0$, dividing form (a) by $-c_0$ puts it as

$$\frac{y_1^2}{a_1^2} + \cdots + \frac{y_n^2}{a_n^2} = 1 \quad \text{with} \quad \frac{1}{a_i^2} = \frac{\lambda_i}{-c_0},$$

whenever all the ratios $\lambda_i/(-c_0)$ are positive, which is the ellipsoid case. The **semi-axes** $a_i = \sqrt{-c_0/\lambda_i}$ lie along the eigenvectors, and a large eigenvalue gives a short axis, exactly as in Example (Finding the axes of a conic).

Remark. That last sentence is the Rayleigh quotient in disguise. For a centered ellipsoid $\mathbf{x}^\top \mathbf{A}\mathbf{x} = 1$ with $\mathbf{A}$ positive definite, any point $\mathbf{x}$ on it has $R_{\mathbf{A}}(\mathbf{x}) = \mathbf{x}^\top \mathbf{A}\mathbf{x}/\|\mathbf{x}\|^2 = 1/\|\mathbf{x}\|^2$. By Proposition 16.1.1 the quotient attains its maximum $\lambda_{\max}$ at a top eigenvector, and since $R_{\mathbf{A}}$ is unchanged by scaling while every non-zero vector scales to a point of the ellipsoid, the maximum over the ellipsoid is that same $\lambda_{\max}$, attained at the scaled top eigenvector; so $\|\mathbf{x}\|$ attains its **minimum** $1/\sqrt{\lambda_{\max}}$ there: the shortest semi-axis points along the eigenvector of the largest eigenvalue. The longest does the same with the smallest eigenvalue. Chapter 23 uses the same picture for a vibrating chain whose masses are all equal, where the eigenvalues are squared frequencies and the principal axes are the shapes in which the chain vibrates.

Example. (One conic, two classifications)

Over $\mathbb{R}$, consider

$$Q(x, y) = 5x^2 + 4xy + 5y^2 - 14x - 14y - 7.$$

Classify its zero set affinely, and then find its center, principal axes and semi-axes.

Solution. The small and big matrices are

$$\mathbf{A} = \begin{pmatrix} 5 & 2 \\ 2 & 5 \end{pmatrix}, \qquad \widetilde{\mathbf{A}} = \begin{pmatrix} 5 & 2 & -7 \\ 2 & 5 & -7 \\ -7 & -7 & -7 \end{pmatrix},$$

the off-diagonal 2 being half of 4 and the -7 in the last column being half of -14.

Center. $\det \mathbf{A} = 21 \neq 0$, so by Proposition 21.5.2 (b) there is exactly one center, the solution of $\mathbf{A}\mathbf{p} = -\mathbf{b} = (7, 7)$, namely $\mathbf{p} = (1, 1)$. Then $c_0 = Q(1, 1) = 5 + 4 + 5 - 14 - 14 - 7 = -21$.

Affine route. By Proposition 21.5.2 (c), translating to $\mathbf{p}$ gives $5X^2 + 4XY + 5Y^2 - 21$ with $X = x - 1$, $Y = y - 1$. Completing the square,

$$5X^2 + 4XY + 5Y^2 = 5\Big(X + \tfrac{2}{5}Y\Big)^2 + \tfrac{21}{5}Y^2,$$

since $5 - \frac{4}{5} = \frac{21}{5}$. So with $s = X + \frac{2}{5}Y$ and $t = Y$ the equation is $5s^2 + \frac{21}{5}t^2 = 21$, and the further scaling $w_1 = \sqrt{5/21}\, s$, $w_2 = t/\sqrt{5}$ gives $w_1^2 + w_2^2 = 1$. The inertia of $\mathbf{A}$ is $(2, 0, 0)$ and that of $\widetilde{\mathbf{A}}$ is $(2, 1, 0)$, since $\det \widetilde{\mathbf{A}} = (\det \mathbf{A})c_0 = -441 < 0$ forces one negative eigenvalue and $\mathbf{A}$ supplies two positive ones. Row 1 of the table: an **ellipse**.

Euclidean route. The characteristic polynomial of $\mathbf{A}$ is $x^2 - 10x + 21 = (x - 3)(x - 7)$,

so the eigenvalues are 3 and 7 with unit eigenvectors

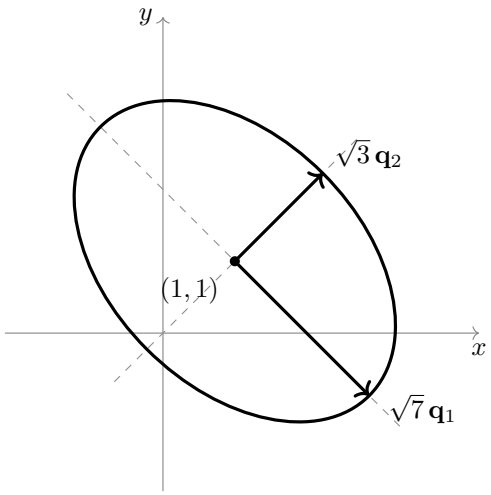
$$\mathbf{q}_1 = \tfrac{1}{\sqrt{2}}(1,-1), \qquad \mathbf{q}_2 = \tfrac{1}{\sqrt{2}}(1,1),$$

as $\mathbf{A}(1,-1) = (3,-3)$ and $\mathbf{A}(1,1) = (7,7)$. By Theorem 21.5.4 the motion $\mathbf{x} = \mathbf{U}\mathbf{y} + \mathbf{p}$ with $\mathbf{U} = (\mathbf{q}_1\ \mathbf{q}_2)$ turns Q into $3y_1^2 + 7y_2^2 - 21$, that is

$$\frac{y_1^2}{7} + \frac{y_2^2}{3} = 1.$$

So the ellipse is centered at $(1,1)$, with semi-axis $\sqrt{7}$ along $\mathbf{q}_1$ and semi-axis $\sqrt{3}$ along $\mathbf{q}_2$. Check the longer one: the point $(1,1) + \sqrt{7}\,\mathbf{q}_1 = \big(1 + \sqrt{7/2},\ 1 - \sqrt{7/2}\big)$ has $X = -Y = \sqrt{7/2}$, and $5X^2 + 4XY + 5Y^2 = (5 - 4 + 5) \cdot \frac{7}{2} = 21$, as required.

What each route saw. Both say "ellipse". Only the Euclidean one says which ellipse: the affine route ended at a circle of radius 1, having first sheared the plane by $s = X + \frac{2}{5}Y$ and then stretched it by the unequal factors $\sqrt{5/21}$ and $1/\sqrt{5}$ to get there.



$5x^2 + 4xy + 5y^2 - 14x - 14y - 7 = 0$: center $(1,1)$, axes along the eigenvectors of $\left(\begin{smallmatrix} \frac{5}{2} & \frac{2}{5} \end{smallmatrix}\right)$

The two classifications answer two different questions, and it is worth being blunt about which is which. The affine one asks what the quadric is *made of* — a curve, a pair of lines, a point, nothing — and its invariants are two inertias. The Euclidean one asks what the quadric *looks like*, and its invariants are the eigenvalues themselves. Section 10 asks a third question, the projective one, and the answer there is shorter than both.

21.5.7 Exercises

21.5.7.1 A. Check your understanding

Exercise A1.

(a) State Definition 21.5.1, including every clause on $\mathbf{A}$, and say what goes wrong if the clause "non-zero" is dropped.

(b) Write down the big matrix $\widetilde{\mathbf{A}}$ of $3x^2 - 2xy + y^2 + 4x - 2$ over $\mathbb{R}$.

(c) Name the three places in this section where $\operatorname{char} F \neq 2$ is used.

(d) True or false: two quadric polynomials with the same zero set are affinely equivalent. Justify your answer.

(e) A quadric on $\mathbb{R}^5$ has $\operatorname{rank} \mathbf{A} = 3$ and $\operatorname{rank} \widetilde{\mathbf{A}} = 5$. Which of the three families of Theorem 21.5.3 does it belong to, and is it central?

Solution.

(a) $Q(\mathbf{x}) = \mathbf{x}^\top \mathbf{A}\mathbf{x} + 2\mathbf{b}^\top \mathbf{x} + c$ with $\mathbf{A} \in M_n(F)$ symmetric and non-zero, $\mathbf{b} \in F^n$, $c \in F$, over a field of characteristic $\neq 2$. If $\mathbf{A} = \mathbf{0}$ were allowed, Q would be an affine function and its zero set a flat or all of F^n; nothing quadratic would remain, and Theorem 21.5.3, whose first step diagonalizes a small matrix of rank $r \geq 1$, would have nothing to work on.

(b) The coefficient of xy is -2, so $a_{12} = -1$; the coefficient of x is 4, so $b_1 = 2$; there is no y term, so $b_2 = 0$. Hence

$$\widetilde{\mathbf{A}} = \begin{pmatrix} 3 & -1 & 2 \\ -1 & 1 & 0 \\ 2 & 0 & -2 \end{pmatrix}.$$

(c) Writing a linear part $\sum \beta_i x_i$ as $2\mathbf{b}^\top \mathbf{x}$; recovering a **symmetric** $\mathbf{A}$ from the quadratic part, where the off-diagonal entries are halves (Theorem 13.3.5); and dividing by 4 in Eq. 21.5.1 to get the center equation $\mathbf{A}\mathbf{p} + \mathbf{b} = \mathbf{0}$.

(d) False. Over $\mathbb{R}$, $x^2 + y^2 + 1$ and $x^2 + 1$ both have empty zero set, but $\operatorname{rank} \mathbf{A}$ is 2 for the first and 1 for the second, and rank is an affine invariant by Proposition 21.5.1.

(e) $\operatorname{rank} \widetilde{\mathbf{A}} = \operatorname{rank} \mathbf{A} + 2$, so it is family (III), and family (III) is exactly the centerless case by Theorem 21.5.3.

21.5.7.2 B. Practice

Exercise B1: Centers.

For each of the following quadric polynomials over $\mathbb{R}$, determine the set of centers. Justify your answer.

(a) $2x^2 + 3y^2 - 4x + 6y + 1$.

(b) $x^2 - 4xy + 4y^2 + 2x - 4y + 5$.

(c) $x^2 - 4xy + 4y^2 + 2x + y$.

Solution. In each case solve $\mathbf{A}\mathbf{p} = -\mathbf{b}$ (Proposition 21.5.2 (a)).

(a) $\mathbf{A} = \operatorname{diag}(2, 3)$, $\mathbf{b} = (-2, 3)$. Since $\mathbf{A}$ is invertible the center is unique: $\mathbf{p} = -\mathbf{A}^{-1}\mathbf{b} = (1, -1)$.

(b) $\mathbf{A} = \left(\begin{smallmatrix} 1 & -2 \\ -2 & 4 \end{smallmatrix}\right)$, which has rank 1 with $\operatorname{col}(\mathbf{A}) = \operatorname{span}((1, -2))$, and $\mathbf{b} = (1, -2) \in \operatorname{col}(\mathbf{A})$. So centers exist, and they solve $p_1 - 2p_2 = -1$: the line $x - 2y + 1 = 0$. (Consistently, the polynomial is $(x - 2y + 1)^2 + 4$, whose zero set is empty but whose equation is symmetric about that line.)

(c) Same $\mathbf{A}$, but $\mathbf{b} = (1, \frac{1}{2})$. If $\mathbf{b}$ were in $\operatorname{col}(\mathbf{A}) = \operatorname{span}((1, -2))$ its second entry

would be -2 times its first, and $\frac{1}{2} \neq -2$. So there is no center; this is a parabola.

Exercise B2: Affine type.

Classify the conic $x^2 + 6xy + y^2 - 4x - 4y + 3 = 0$ over $\mathbb{R}$: find $\operatorname{In} \mathbf{A}$ and $\operatorname{In} \widetilde{\mathbf{A}}$, name the row of the table, and exhibit the invertible affine substitution that reaches the normal form.

Solution. Here $\mathbf{A} = \left(\begin{smallmatrix} 1 & 3 \\ 3 & 1 \end{smallmatrix}\right)$ and $\mathbf{b} = (-2, -2)$, $c = 3$. The eigenvalues of $\mathbf{A}$ are 4 and -2, from $x^2 - 2x - 8 = (x - 4)(x + 2)$, so $\operatorname{In} \mathbf{A} = (1, 1, 0)$ by Theorem 13.5.3, and $\det \mathbf{A} = -8 \neq 0$.

The unique center solves $\mathbf{A}\mathbf{p} = (2, 2)$, giving $\mathbf{p} = (\frac{1}{2}, \frac{1}{2})$, and $c_0 = Q(\mathbf{p}) = \frac{1}{4} + \frac{3}{2} + \frac{1}{4} - 2 - 2 + 3 = 1$. Translating, the equation becomes $X^2 + 6XY + Y^2 + 1 = 0$ with $X = x - \frac{1}{2}$, $Y = y - \frac{1}{2}$. Completing the square, $X^2 + 6XY + Y^2 = (X + 3Y)^2 - 8Y^2$, so with $s = X + 3Y$, $t = Y$ the equation is $s^2 - 8t^2 = -1$. Multiplying by -1 and setting $w_1 = 2\sqrt{2}\, t$, $w_2 = s$ gives $w_1^2 - w_2^2 = 1$.

So $\widetilde{\mathbf{A}}$ is congruent to $\operatorname{diag}(1, -8, 1)$ up to the translation, giving $\operatorname{In} \widetilde{\mathbf{A}} = (2, 1, 0)$; up to the simultaneous exchange this is the invariant $\big((1, 1, 0), (1, 2, 0)\big)$ of row 2. The conic is a **hyperbola**.

Exercise B3: Principal axes.

Find the center, principal axes and semi-axes of $2x^2 - 4xy + 5y^2 - 4x + 2y - 7 = 0$ over $\mathbb{R}$.

Solution. $\mathbf{A} = \left(\begin{smallmatrix} 2 & -2 \\ -2 & 5 \end{smallmatrix}\right)$, $\mathbf{b} = (-2, 1)$, $c = -7$. Since $\det \mathbf{A} = 6 \neq 0$ the center solves $\mathbf{A}\mathbf{p} = (2, -1)$: from $2p_1 - 2p_2 = 2$ and $-2p_1 + 5p_2 = -1$ we get $p_2 = \frac{1}{3}$, $p_1 = \frac{4}{3}$. Then

$$c_0 = Q(\mathbf{p}) = \mathbf{b}^{\top}\mathbf{p} + c = (-2)\tfrac{4}{3} + 1 \cdot \tfrac{1}{3} - 7 = -\tfrac{28}{3},$$

using $Q(\mathbf{p}) = \mathbf{p}^{\top}(\mathbf{A}\mathbf{p} + \mathbf{b}) + \mathbf{b}^{\top}\mathbf{p} + c = \mathbf{b}^{\top}\mathbf{p} + c$, valid because $\mathbf{A}\mathbf{p} + \mathbf{b} = \mathbf{0}$.

The characteristic polynomial is $x^2 - 7x + 6 = (x - 1)(x - 6)$, so $\lambda = 1, 6$ with unit eigenvectors $\mathbf{q}_1 = \frac{1}{\sqrt{5}}(2, 1)$ and $\mathbf{q}_2 = \frac{1}{\sqrt{5}}(1, -2)$; indeed $\mathbf{A}(2, 1) = (2, 1)$ and $\mathbf{A}(1, -2) = (6, -12)$. By Theorem 21.5.4 the normal form is $y_1^2 + 6y_2^2 - \frac{28}{3} = 0$, that is

$$\frac{y_1^2}{28/3} + \frac{y_2^2}{14/9} = 1.$$

So the curve is an ellipse centered at $(\frac{4}{3}, \frac{1}{3})$, with semi-axis $2\sqrt{21}/3 = \sqrt{28/3}$ along $\mathbf{q}_1$ and semi-axis $\sqrt{14}/3$ along $\mathbf{q}_2$.

21.5.7.3 C. Going deeper

Exercise C1: Which quadrics are determined by their points.

Work over $\mathbb{R}$ with $n = 2$.

(a) Give two quadric polynomials with the same zero set that are **not** proportional.

(b) Prove that if Q is a quadric polynomial whose zero set contains three points of some line L, then Q vanishes on all of L.

(c) Deduce that the zero set of a quadric polynomial is never exactly a set of three non-collinear points.

Hint for (b): restrict Q to a parametrization of L.

Solution.

(a) Take $Q_1 = x^2 + y^2$ and $Q_2 = x^2 + 2y^2$. Both vanish exactly at $\mathbf{0}$, since a sum of squares of reals is zero only when each is, but $Q_2 \neq \lambda Q_1$ for any λ: comparing the coefficients of x^2 forces $\lambda = 1$, and then the coefficients of y^2 disagree.

(b) Write $L = \{\mathbf{p} + t\mathbf{v} : t \in \mathbb{R}\}$ with $\mathbf{v} \neq \mathbf{0}$, a flat of dimension 1 (Definition 21.2.1). Then

$$f(t) = Q(\mathbf{p} + t\mathbf{v}) = (\mathbf{v}^\top \mathbf{A}\mathbf{v})t^2 + 2\big(\mathbf{v}^\top(\mathbf{A}\mathbf{p} + \mathbf{b})\big)t + Q(\mathbf{p})$$

by the expansion in the proof of Proposition 21.5.2, so f is a polynomial of degree at most 2 in t. If Q vanishes at three distinct points of L, then f has three distinct roots. A non-zero polynomial of degree at most 2 over a field has at most 2 roots (Corollary 5.1.4), so f is the zero polynomial and Q vanishes on all of L.

(c) Suppose, for a contradiction, that the zero set of a quadric polynomial Q is exactly $\{P_1, P_2, P_3\}$ with the three points not collinear, that is affinely independent (Definition 17.2.1). Then (P_1, P_2, P_3) is an affine frame of $\mathbb{R}^2$ (Definition 21.2.4), so by Theorem 21.2.8 there is an affine map f carrying it to the frame $\big((0,0),(1,0),(0,1)\big)$. That f is invertible: by Theorem 21.1.5 (b) its linear part sends $\overrightarrow{P_1P_2}$ to $\mathbf{e}_1$ and $\overrightarrow{P_1P_3}$ to $\mathbf{e}_2$, so it carries a basis to a basis and is invertible, whence f is bijective by Proposition 21.1.7. Substituting by f^{-1}, we may therefore assume the three points **are** $(0,0)$, $(1,0)$, $(0,1)$, since an invertible affine substitution carries the zero set bijectively to the zero set (Proposition 21.5.1).

Write $Q = ax^2 + 2hxy + by^2 + 2dx + 2ey + c$. Then $Q(0,0) = c = 0$, $Q(1,0) = a + 2d = 0$ and $Q(0,1) = b + 2e = 0$, so

$$Q = a\,x(x-1) + b\,y(y-1) + 2hxy.$$

Restricting to the line $y = 0$ gives $a\,x(x-1)$. If $a = 0$ this vanishes identically and the whole line lies in the zero set, which is impossible for a three-point set; so $a \neq 0$, and by the same argument on $x = 0$, $b \neq 0$.

Now fix $m \in \mathbb{R}$ with $m \neq 0$ and restrict to the line $y = mx$:

$$Q(t, mt) = t\big[(a + 2hm + bm^2)\,t - (a + bm)\big].$$

The only point of $\{P_1, P_2, P_3\}$ on that line is $(0,0)$, because $(1,0)$ needs $m = 0$ and $(0,1)$ is not of the form (t, mt). So $t = 0$ must be the only root. If $a + 2hm + bm^2 \neq 0$, the bracket vanishes at $t = (a + bm)/(a + 2hm + bm^2)$, and that must be 0, forcing $a + bm = 0$. Hence for every $m \neq 0$,

$$a + 2hm + bm^2 = 0 \qquad \text{or} \qquad a + bm = 0.$$

The first equation is a quadratic in m with leading coefficient $b \neq 0$, so it has at most 2 roots, and the second has exactly one since $b \neq 0$ (Corollary 5.1.4). That is at most three permitted values of m, while $\mathbb{R} \setminus \{0\}$ is infinite. Contradiction. Hence no quadric polynomial over $\mathbb{R}$ has exactly three non-collinear points as its zero set.

Exercise C2: Over another field.

(a) Over $\mathbb{C}$, prove that every quadric polynomial in n variables is equivalent, under an invertible affine substitution and a non-zero scalar, to one of $\sigma_r(\mathbf{y}) - 1$, $\sigma_r(\mathbf{y})$, or $\sigma_r(\mathbf{y}) - y_{r+1}$ with $r < n$, where $\sigma_r(\mathbf{y}) = y_1^2 + \cdots + y_r^2$. How many normal forms are there for $n = 2$?

(b) Over $\mathbb{F}_3$, how many points does the conic $x^2 + y^2 - 1 = 0$ have in $\mathbb{F}_3^2$? And $x^2 + y^2 = 0$?

Solution.

(a) Repeat the proof of Theorem 21.5.3, replacing Corollary 13.5.2 by Corollary 13.4.4, which says that over $\mathbb{C}$ a symmetric matrix of rank r is congruent to $\mathbf{I}_r \oplus \mathbf{0}_{n-r}$: rank alone is the congruence invariant. Step 1 gives $\sigma_r + 2\mathbf{b}_1^{\top}\mathbf{y} + c$; Step 2 is unchanged; and in Step 3 Case A with $c_2 \neq 0$ we substitute $z_i = \gamma w_i$ for $i \leq r$ with $\gamma^2 = -c_2$, possible because every complex number has a square root, and obtain $\sigma_r - 1$ after dividing by $-c_2$. No sign remains to normalize, and no p survives, so the invariants reduce to $(\operatorname{rank}\mathbf{A}, \operatorname{rank}\widetilde{\mathbf{A}}) = (r, r+1), (r, r), (r, r+2)$, which are pairwise distinct. For $n = 2$: $r = 1$ gives three forms and $r = 2$ gives two (family (III) needs $r < n$), so **five** in all, against nine over $\mathbb{R}$. The four forms that disappear are accounted for by inertia: over $\mathbb{C}$ the ellipse, the hyperbola and the empty conic $x^2 + y^2 + 1$ all become $\sigma_2 - 1$; the point and the crossing lines both become σ_2; and $x^2 = 1$ and $x^2 = -1$ both become $\sigma_1 - 1$, the last two because $i^2 = -1$.

(b) The squares in $\mathbb{F}_3$ are $0^2 = 0$, $1^2 = 1$, $2^2 = 1$, so $x^2 \in \{0, 1\}$ and $x^2 = 1$ has two solutions while $x^2 = 0$ has one. For $x^2 + y^2 = 1$: either $x^2 = 1$ and $y^2 = 0$, giving $2 \cdot 1 = 2$ points, or $x^2 = 0$ and $y^2 = 1$, giving $1 \cdot 2 = 2$ points; and $1 + 1 = 2 \neq 1$ rules out the remaining combination. Total **4** points, namely $(\pm 1, 0)$ and $(0, \pm 1)$. For $x^2 + y^2 = 0$: the options are $0 + 0$ only, since $1 + 1 = 2 \neq 0$ and $1 + 0 = 1 \neq 0$. Total **1** point, the origin. So over $\mathbb{F}_3$ this "circle" behaves like a real circle in the first case and like the real point-conic in the second, because -1 is not a square in $\mathbb{F}_3$.

Exercise C3: The center as a projection.

Let $Q(\mathbf{x}) = \mathbf{x}^{\top}\mathbf{A}\mathbf{x} + 2\mathbf{b}^{\top}\mathbf{x} + c$ be a central quadric polynomial on $\mathbb{R}^n$ with $r = \operatorname{rank}\mathbf{A}$.

(a) Prove that the set of centers is a flat of dimension $n - r$ (Definition 21.2.1).

(b) Prove that the set of centers is contained in the zero set of Q if and only if $Q(\mathbf{p}) = 0$ for one, hence every, center $\mathbf{p}$.

(c) Give an example on $\mathbb{R}^3$ with a line of centers, none of which lies on the quadric.

Solution.

(a) By Proposition 21.5.2 (a) the centers are the solutions of $\mathbf{A}\mathbf{p} = -\mathbf{b}$, a consistent

linear system. By Theorem 2.1.3 its solution set is $\mathbf{p}_0 + \operatorname{nul}(\mathbf{A})$ for any particular solution $\mathbf{p}_0$, a coset of $\operatorname{nul}(\mathbf{A})$, hence a flat with direction space $\operatorname{nul}(\mathbf{A})$. Its dimension is $\dim \operatorname{nul}(\mathbf{A}) = n - \operatorname{rank} \mathbf{A} = n - r$ by the Rank-Nullity Theorem (Theorem 3.3.1).

(b) By Proposition 21.5.2 (c) the value $Q(\mathbf{p})$ is the same at every center, so "for one" and "for every" agree; and the set of centers lies in the zero set exactly when that common value is 0.

(c) Take $Q(x, y, z) = x^2 + y^2 - 1$ on $\mathbb{R}^3$. Here $\mathbf{A} = \operatorname{diag}(1, 1, 0)$ has rank 2, $\mathbf{b} = \mathbf{0} \in \operatorname{col}(\mathbf{A})$, and the centers are the solutions of $\mathbf{Ap} = \mathbf{0}$, namely the z-axis, a line as (a) predicts with $n - r = 1$. The common value is $Q(0, 0, z) = -1 \neq 0$, so no center lies on the quadric, which is the cylinder of radius 1 about the z-axis.

21.6 Projective Space

The affine geometry of the first two sections has one flaw, and it is visible in the statement of Theorem 21.2.4: the formula for the dimension of a join has two cases, because two flats may fail to meet. This section builds a geometry in which that never happens. The construction is entirely linear — a projective space is the set of lines through the origin of a vector space — and the payoff is a dimension formula with no exceptional case at all. Everything here works over an arbitrary field F, and neither analysis nor topology enters.

21.6.1 Two lines that do not meet

In the affine plane $\mathbb{A}^2(\mathbb{R})$, take

$$L_1 = \{(y_1, y_2) : y_2 - y_1 = 0\}, \qquad L_2 = \{(y_1, y_2) : y_2 - y_1 = 1\}.$$

A point in both would satisfy $0 = 1$, so $L_1 \cap L_2 = \emptyset$. Both are flats of dimension 1 with the same direction space $\operatorname{span}((1, 1))$, and their join is the whole plane. So Theorem 21.2.4 (c) is in its second case: $\dim(L_1 \vee L_2) = 1 + 1 - 1 + 1 = 2$, with the extra $+1$ paid for by the failure to meet, and there is nothing to substitute for $\dim(L_1 \cap L_2)$, because the empty set has no dimension.

The two lines do have something in common: a direction. They are going the same way, and the natural thing to say is that they meet "at infinity". The whole of this section is the work of turning that phrase into mathematics without losing linearity. The repair, in one sentence: *stop working with points of a vector space and start working with its lines through the origin.*

21.6.2 The projective space of a vector space

Let V be a vector space over F. On $V \setminus \{\mathbf{0}\}$ define

$$\mathbf{x} \sim \mathbf{y} \quad \text{if and only if} \quad \mathbf{y} = \lambda \mathbf{x} \text{ for some } \lambda \in F,\ \lambda \neq 0.$$

This is an equivalence relation (Definition 0.5.2): it is reflexive with $\lambda = 1$; symmetric, because $\mathbf{y} = \lambda \mathbf{x}$ with $\lambda \neq 0$ gives $\mathbf{x} = \lambda^{-1} \mathbf{y}$; and transitive, because $\mathbf{y} = \lambda \mathbf{x}$ and $\mathbf{z} = \mu \mathbf{y}$ give $\mathbf{z} = (\mu\lambda)\mathbf{x}$ with $\mu\lambda \neq 0$, a field having no zero divisors. Note that $\mathbf{0}$ had to be removed: it is equivalent only to itself, and keeping it would put a single extra point into every picture with no geometric job.

A point of projective space is a line through the origin, with the origin itself thrown away.

Definition 21.6.1 — Projective Space

Let V be a finite-dimensional vector space over a field F with $\dim V = n+1$. The **projective space** of V is the quotient set (Definition 0.5.5)

$$\mathbb{P}(V) = (V \setminus \{\mathbf{0}\})/\!\sim,$$

whose elements are called **points**. The point determined by $\mathbf{x} \neq \mathbf{0}$ is written $[\mathbf{x}]$. The **dimension** of $\mathbb{P}(V)$ is

$$\dim \mathbb{P}(V) = \dim V - 1 = n,$$

so that $\mathbb{P}(\{\mathbf{0}\}) = \emptyset$ has dimension -1. We write $\mathbb{P}^n(F) = \mathbb{P}(F^{n+1})$ for **projective n-space over F**. A projective space of dimension 1 is a **projective line**, and one of dimension 2 a **projective plane**.

Two clauses need comment. The shift by one in the dimension is not a decoration: it is what makes a projective line behave like a line and a projective plane like a plane, as Theorem 21.6.2 is about to confirm. And the convention $\dim \emptyset = -1$ looks like a dodge, but it is forced by the same shift — the empty set is $\mathbb{P}(\{\mathbf{0}\})$ and $\dim\{\mathbf{0}\} = 0$ — and it will do real work in Theorem 21.6.6.

Proposition 21.6.1 — Points Are Lines Through the Origin

Let V be a finite-dimensional vector space over F. The map $[\mathbf{x}] \mapsto \operatorname{span}(\mathbf{x})$ is a bijection from $\mathbb{P}(V)$ onto the set of 1-dimensional subspaces of V.

Proof. Well defined. If $[\mathbf{x}] = [\mathbf{y}]$ then $\mathbf{y} = \lambda\mathbf{x}$ with $\lambda \neq 0$, so $\operatorname{span}(\mathbf{y}) = \operatorname{span}(\mathbf{x})$ because each of $\mathbf{x}, \mathbf{y}$ is a scalar multiple of the other. Also $\mathbf{x} \neq \mathbf{0}$, so $\operatorname{span}(\mathbf{x})$ has dimension 1.

Injective. If $\operatorname{span}(\mathbf{x}) = \operatorname{span}(\mathbf{y})$ with $\mathbf{x}, \mathbf{y} \neq \mathbf{0}$, then $\mathbf{y} = \lambda\mathbf{x}$ for some $\lambda \in F$, and $\lambda \neq 0$ since $\mathbf{y} \neq \mathbf{0}$. Hence $[\mathbf{x}] = [\mathbf{y}]$.

Surjective. A 1-dimensional subspace has a basis $(\mathbf{x})$ with $\mathbf{x} \neq \mathbf{0}$, and then it is $\operatorname{span}(\mathbf{x})$, the image of $[\mathbf{x}]$. This proves the proposition.

■

So a point of $\mathbb{P}^2(F)$ is a line through the origin of F^3, and a "line" of the projective plane will turn out to be a plane through the origin of F^3. Every statement below can be read twice: once about $\mathbb{P}(V)$ and once about subspaces of V.

Definition 21.6.2 — Homogeneous Coordinates

Let $\mathbf{x} = (x_0, x_1, \dots, x_n) \in F^{n+1}$ be non-zero. The **homogeneous coordinates** of the point $[\mathbf{x}] \in \mathbb{P}^n(F)$ are written

$$[\mathbf{x}] = [x_0 : x_1 : \cdots : x_n],$$

the colons recording that only the ratios are determined: for every $\lambda \neq 0$,

$$[x_0 : x_1 : \cdots : x_n] = [\lambda x_0 : \lambda x_1 : \cdots : \lambda x_n],$$

and not all of $x_0, \ldots, x_n$ are zero.

Coordinates run from 0. In F^{n+1} we index the entries and the standard basis from 0, writing $\mathbf{x} = (x_0, x_1, \ldots, x_n)$ and $\mathbf{e}_0, \ldots, \mathbf{e}_n$, and every projective section of this chapter does the same. Subscripts start at 1 everywhere else in the book; the exception pays for itself here, because it keeps the n of $\mathbb{P}^n(F)$ equal to the dimension while the coordinates number $n+1$.

Examples.

- $\mathbb{P}^0(F) = \mathbb{P}(F^1)$ has exactly one point, $[1]$, since every non-zero scalar is a non-zero multiple of 1. Its dimension is 0, as a single point should have.
- $\mathbb{P}^1(F)$ consists of the points $[1 : a]$ for $a \in F$, all distinct, together with the single point $[0 : 1]$. Indeed if $x_0 \neq 0$ then $[x_0 : x_1] = [1 : x_1/x_0]$, and if $x_0 = 0$ then $x_1 \neq 0$ and $[0 : x_1] = [0 : 1]$.
- $\mathbb{P}^1(\mathbb{F}_2) = \{[1 : 0], [1 : 1], [0 : 1]\}$ has three points. The three lines through the origin of $\mathbb{F}_2^2$ are $\operatorname{span}((1, 0))$, $\operatorname{span}((1, 1))$, $\operatorname{span}((0, 1))$, matching Proposition 21.6.1.
- The degenerate case $\mathbb{P}(\{\mathbf{0}\}) = \emptyset$. It is worth keeping, because intersections produce it.

Non-example by minimal change. Over $\mathbb{R}$, replace the relation by $\mathbf{x} \approx \mathbf{y}$ when $\mathbf{y} = \lambda \mathbf{x}$ with $\lambda > 0$. This is still an equivalence relation, but the quotient is not $\mathbb{P}(V)$: every projective point $[\mathbf{x}]$ splits into the two classes of $\mathbf{x}$ and $-\mathbf{x}$. The clause that fails is the one allowing **every** non-zero λ, and what is lost is precisely the identification of a line with itself traversed backwards.

Warning. **A single homogeneous coordinate means nothing.** The expression "$x_1 = 3$" is not a statement about a point of $\mathbb{P}^n(F)$, since $[1 : 3 : 0] = [2 : 6 : 0]$ and the second coordinate changed. Only two kinds of statement survive scaling: a ratio such as x_1/x_0 where $x_0 \neq 0$, and the vanishing or non-vanishing of a **homogeneous** expression, such as $x_1 = 0$ or $x_0 x_2 - x_1^2 = 0$. Whenever a formula below names a coordinate, check that it survives replacing $\mathbf{x}$ by $\lambda \mathbf{x}$.

21.6.3 The affine chart, and where the missing points live

Here is the theorem that makes the construction worth doing: projective space is an affine space plus a smaller projective space.

Theorem 21.6.2 — The Standard Affine Chart

Let $n \geq 1$ and let

$$U_0 = \{[x_0 : \cdots : x_n] \in \mathbb{P}^n(F) : x_0 \neq 0\},$$
$$H_\infty = \{[x_0 : \cdots : x_n] \in \mathbb{P}^n(F) : x_0 = 0\}.$$

Then:

(a) both conditions are independent of the representative, and $\mathbb{P}^n(F) = U_0 \sqcup H_\infty$, a

disjoint union;

(b) the map $\iota\colon F^n \to U_0$, $\iota(a_1,\dots,a_n) = [1 : a_1 : \cdots : a_n]$, is a bijection, with inverse $[x_0 : \cdots : x_n] \mapsto (x_1/x_0, \dots, x_n/x_0)$;

(c) $H_\infty = \mathbb{P}(W)$ with $W = \{\mathbf{x} \in F^{n+1} : x_0 = 0\}$, so H_∞ has dimension $n-1$, and $[0 : x_1 : \cdots : x_n] \mapsto [x_1 : \cdots : x_n]$ is a bijection $H_\infty \to \mathbb{P}^{n-1}(F)$.

U_0 is the **standard affine chart** and H_∞ the **hyperplane at infinity**.

Idea. Scaling multiplies x_0 by a non-zero number, so it cannot create or destroy a zero there: that single observation makes both halves well defined. On the half where $x_0 \neq 0$ we may **normalize** x_0 to 1, and once $x_0 = 1$ the remaining coordinates are no longer ambiguous, which is why the affine points come back one for one. On the other half x_0 carries no information at all, so it may be deleted, and what is left is one dimension smaller.

Proof.

(a) If $\mathbf{y} = \lambda\mathbf{x}$ with $\lambda \neq 0$ then $y_0 = \lambda x_0$, and a product of two elements of a field is zero only if one of them is, so $y_0 = 0$ exactly when $x_0 = 0$. Hence both defining conditions depend only on the point. Every point satisfies exactly one of them, so the union is disjoint and exhausts $\mathbb{P}^n(F)$.

(b) *Well defined:* $(1, a_1, \dots, a_n) \neq \mathbf{0}$, and its zeroth entry is $1 \neq 0$, so $\iota(\mathbf{a}) \in U_0$.
Injective: if $[1 : \mathbf{a}] = [1 : \mathbf{a}']$ then $(1, \mathbf{a}') = \lambda(1, \mathbf{a})$ for some $\lambda \neq 0$; comparing zeroth entries gives $\lambda = 1$, hence $\mathbf{a}' = \mathbf{a}$.
Surjective: let $[\mathbf{x}] \in U_0$, so $x_0 \neq 0$ and x_0^{-1} exists. Then $x_0^{-1}\mathbf{x} = (1, x_1/x_0, \dots, x_n/x_0)$, so $[\mathbf{x}] = \iota(x_1/x_0, \dots, x_n/x_0)$. The displayed formula for the inverse is exactly this computation, and it is independent of the representative because replacing $\mathbf{x}$ by $\lambda\mathbf{x}$ multiplies numerator and denominator of each ratio by λ.

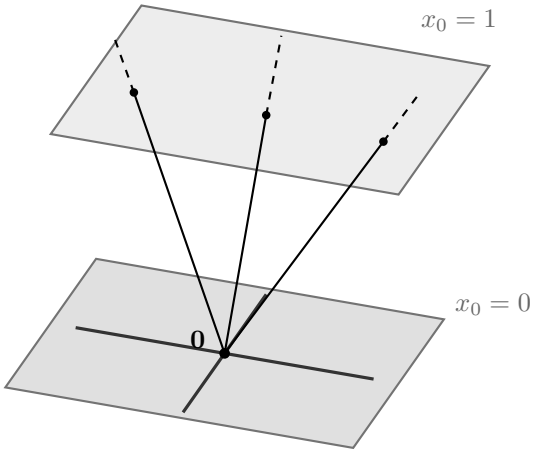
(c) W is a subspace of F^{n+1}, being the kernel of the linear functional $\mathbf{x} \mapsto x_0$, and $\dim W = n$ by the Rank-Nullity Theorem (Theorem 3.3.1), the functional being non-zero and hence surjective onto F (Proposition 4.1.2). A non-zero $\mathbf{x}$ has $x_0 = 0$ exactly when $\mathbf{x} \in W \setminus \{\mathbf{0}\}$, so $H_\infty = \mathbb{P}(W)$ and $\dim H_\infty = n-1$ by Definition 21.6.1. The stated map is well defined, because deleting the zeroth coordinate turns $\lambda\mathbf{x}$ into λ times the deletion and cannot produce $\mathbf{0}$ from a non-zero $\mathbf{x}$ with $x_0 = 0$; it is injective and surjective because inserting a zeroth coordinate 0 inverts it. This proves the theorem.

■

For $n = 2$ the statement reads: **the projective plane is the affine plane together with a projective line.** Writing it out, every point of $\mathbb{P}^2(F)$ is exactly one of

$$[1 : a : b] \quad (a, b \in F), \qquad [0 : 1 : m] \quad (m \in F), \qquad [0 : 0 : 1],$$

the first family being the affine plane through ι, and the last two being the line at infinity $H_\infty \cong \mathbb{P}^1(F)$, which has $|F| + 1$ points when F is finite. The label m is chosen deliberately: the next proposition shows $[0 : 1 : m]$ is the point where all affine lines of slope m meet.



each line through $\mathbf{0}$ is one point of $\mathbb{P}^2(F)$:
those meeting the plane $x_0 = 1$ give the affine chart,
those lying inside the plane $x_0 = 0$ give the line at infinity

Proposition 21.6.3 — Completing an Affine Line

Let $a_1, a_2 \in F$ be not both zero, let $b \in F$, and let

$$L = \{(y_1, y_2) \in F^2 : a_1 y_1 + a_2 y_2 = b\},$$

a flat of dimension 1 in $\mathbb{A}^2$ by Theorem 21.2.10, the single row (a_1, a_2) being non-zero, with direction space $\operatorname{span}((-a_2, a_1))$. Let $\varphi(x_0, x_1, x_2) = a_1 x_1 + a_2 x_2 - b x_0$ and $\bar{L} = \mathbb{P}(\ker \varphi) \subseteq \mathbb{P}^2(F)$. Then:

(a) $\bar{L}$ is a projective line;
(b) $\iota(L) = \bar{L} \cap U_0$, so $\bar{L}$ contains a faithful copy of L;
(c) $\bar{L} \setminus U_0$ is the single point $[0 : -a_2 : a_1]$;
(d) two such lines L, L' have the same direction space if and only if $\bar{L}$ and $\bar{L}'$ meet H_∞ in the same point.

Proof.

(a) φ is linear and non-zero, since $\varphi(0,1,0) = a_1$ and $\varphi(0,0,1) = a_2$ are not both zero. So φ is surjective onto F (Proposition 4.1.2) and $\dim \ker \varphi = 3 - 1 = 2$ by Theorem 3.3.1. Hence $\bar{L} = \mathbb{P}(\ker \varphi)$ has dimension 1.

(b) A point of U_0 is $\iota(y_1, y_2) = [1 : y_1 : y_2]$ by Theorem 21.6.2 (b), and $\varphi(1, y_1, y_2) = a_1 y_1 + a_2 y_2 - b$. This vanishes exactly when $(y_1, y_2) \in L$. Since φ is homogeneous of degree 1, the vanishing does not depend on the representative.

(c) A point of $\bar{L} \setminus U_0$ has $x_0 = 0$ and $a_1 x_1 + a_2 x_2 = 0$ with $(x_1, x_2) \neq (0, 0)$. The solution set of that single non-trivial equation in F^2 is $\operatorname{span}((-a_2, a_1))$, of dimension 1, so there is exactly one such projective point, namely $[0 : -a_2 : a_1]$.

(d) By (c) the point in question is $[0 : -a_2 : a_1]$, which by Proposition 21.6.1 determines and is determined by $\operatorname{span}((-a_2, a_1))$, the direction space of L. This proves the proposition.

■

Now return to the hook. The lines $L_1 : y_2 - y_1 = 0$ and $L_2 : y_2 - y_1 = 1$ have $(a_1, a_2) = (-1, 1)$ and $b = 0$ respectively $b = 1$, so

$$\bar{L}_1 : x_2 - x_1 = 0, \qquad \bar{L}_2 : x_2 - x_1 - x_0 = 0.$$

Subtracting the two equations gives $x_0 = 0$, and then $x_2 = x_1$ with $(x_1, x_2) \neq (0, 0)$. So

$$\bar{L}_1 \cap \bar{L}_2 = \{[0 : 1 : 1]\},$$

exactly one point, and it lies on the line at infinity. By Proposition 21.6.3 (c) that point is $[0 : -a_2 : a_1] = [0 : -1 : -1] = [0 : 1 : 1]$ for both lines, which is their common direction $\operatorname{span}((1, 1))$ read as a point. Two parallel lines meet at their shared direction, and nowhere else.

> *Quick check.* In $\mathbb{P}^2(\mathbb{R})$, which point of the line at infinity do all the **vertical** affine lines $y_1 = c$ pass through, and which point do all lines of slope m pass through?

> *Solution.* A vertical line $y_1 = c$ has $(a_1, a_2) = (1, 0)$, so by Proposition 21.6.3 (c) its point at infinity is $[0 : -a_2 : a_1] = [0 : 0 : 1]$. A line $y_2 = my_1 + k$, that is $my_1 - y_2 = -k$, has $(a_1, a_2) = (m, -1)$ and point at infinity $[0 : 1 : m]$. So the points of H_∞ are $[0 : 1 : m]$ for each slope $m \in \mathbb{R}$, plus $[0 : 0 : 1]$ for the vertical direction: one point per direction, and the vertical direction is no longer a special case.

21.6.4 Projective subspaces, and a dimension formula with one case

Definition 21.6.3 — Projective Subspace

Let V be a finite-dimensional vector space over F. A **projective subspace** of $\mathbb{P}(V)$ is a subset of the form

$$\mathbb{P}(U) = \{[\mathbf{x}] : \mathbf{x} \in U \setminus \{\mathbf{0}\}\}$$

for a subspace U of V. Its **dimension** is $\dim U - 1$. A projective subspace of dimension 0 is a **point**, of dimension 1 a **line**, of dimension 2 a **plane**, and of dimension $\dim \mathbb{P}(V) - 1$ a **hyperplane**.

The dimension is only well defined if U can be recovered from $\mathbb{P}(U)$. It can, and the reason is worth isolating.

Lemma 21.6.4 — A Projective Subspace Remembers Its Subspace

Let U and W be subspaces of V. Then $\mathbb{P}(U) \subseteq \mathbb{P}(W)$ if and only if $U \subseteq W$; in particular $\mathbb{P}(U) = \mathbb{P}(W)$ forces $U = W$.

> *Proof.* ($\Leftarrow$) Immediate from the definition.
>
> ($\Rightarrow$) Suppose $\mathbb{P}(U) \subseteq \mathbb{P}(W)$ and let $\mathbf{x} \in U$. If $\mathbf{x} = \mathbf{0}$ then $\mathbf{x} \in W$. Otherwise $[\mathbf{x}] \in \mathbb{P}(U) \subseteq \mathbb{P}(W)$, so $[\mathbf{x}] = [\mathbf{w}]$ for some $\mathbf{w} \in W \setminus \{\mathbf{0}\}$, that is $\mathbf{x} = \lambda \mathbf{w}$ with $\lambda \neq 0$; hence $\mathbf{x} \in W$, W being a subspace. So $U \subseteq W$.
>
> For the last claim, apply the equivalence in both directions and use that $\subseteq$ is antisymmetric. This proves the lemma.

■

Proposition 21.6.5 — Meet and Join

Let $S = \mathbb{P}(U)$ and $T = \mathbb{P}(W)$ be projective subspaces of $\mathbb{P}(V)$. Then:

(a) $S \cap T = \mathbb{P}(U \cap W)$, so an intersection of projective subspaces is a projective subspace;

(b) among all projective subspaces containing $S \cup T$ there is a smallest one, namely $\mathbb{P}(U + W)$.

We write $S \vee T = \mathbb{P}(U + W)$ and call it the **join** of S and T.

Proof.

(a) Let $\mathbf{x} \neq \mathbf{0}$. By Lemma 21.6.4 applied to $\operatorname{span}(\mathbf{x})$, we have $[\mathbf{x}] \in \mathbb{P}(U)$ exactly when $\mathbf{x} \in U$. Hence $[\mathbf{x}] \in S \cap T$ exactly when $\mathbf{x} \in U$ and $\mathbf{x} \in W$, that is $\mathbf{x} \in (U \cap W) \setminus \{\mathbf{0}\}$, which says $[\mathbf{x}] \in \mathbb{P}(U \cap W)$.

(b) $U \subseteq U + W$ and $W \subseteq U + W$, so $\mathbb{P}(U + W)$ contains $S \cup T$ by Lemma 21.6.4. Conversely, if $\mathbb{P}(Y) \supseteq S \cup T$ for a subspace Y, then the same lemma gives $U \subseteq Y$ and $W \subseteq Y$, hence $U + W \subseteq Y$ because $U + W$ is the smallest subspace containing both (Theorem 1.7.1), and so $\mathbb{P}(U + W) \subseteq \mathbb{P}(Y)$. This proves the proposition.

■

Theorem 21.6.6 — Projective Dimension Formula

Let S and T be projective subspaces of a finite-dimensional projective space. Then

$$\dim(S \vee T) + \dim(S \cap T) = \dim S + \dim T. \tag{21.6.1}$$

There is **no exceptional case**: the identity holds for all S and T, including when $S \cap T = \emptyset$, where $\dim(S \cap T) = -1$.

Idea. There is nothing to invent. Write S and T as $\mathbb{P}(U)$ and $\mathbb{P}(W)$, apply Chapter 1's dimension formula to U and W, and subtract 1 four times. The only thing that needs watching is the bookkeeping of those four -1's, and the reason the formula has no second case is that two of them cancel against the other two even when $U \cap W = \{\mathbf{0}\}$ — which is precisely the situation the affine version could not handle.

Proof. By Definition 21.6.3 write $S = \mathbb{P}(U)$ and $T = \mathbb{P}(W)$; the subspaces U and W are uniquely determined by Lemma 21.6.4. By Proposition 21.6.5, $S \vee T = \mathbb{P}(U + W)$ and

$S \cap T = \mathbb{P}(U \cap W)$. Hence, using Definition 21.6.3 four times and Theorem 1.7.3 once,

$$\begin{aligned}\dim(S \vee T) + \dim(S \cap T) &= \big(\dim(U+W) - 1\big) + \big(\dim(U \cap W) - 1\big) \\ &= \big(\dim U + \dim W\big) - 2 \\ &= \big(\dim U - 1\big) + \big(\dim W - 1\big) \\ &= \dim S + \dim T.\end{aligned}$$

The middle step is Theorem 1.7.3, which holds for **all** subspaces U, W with no hypothesis beyond finite dimension. In particular when $U \cap W = \{\mathbf{0}\}$ the second term on the first line is $0 - 1 = -1$, and the computation is unaffected. This proves the theorem.

■

Compare the two formulas side by side. For flats A, B of an affine space, Theorem 21.2.4 (c) gives

$$\dim(A \vee B) = \begin{cases} \dim A + \dim B - \dim(A \cap B), & A \cap B \neq \emptyset, \\ \dim A + \dim B - \dim(\vec{A} \cap \vec{B}) + 1, & A \cap B = \emptyset, \end{cases}$$

where $\vec{A}, \vec{B}$ are the direction spaces. Two cases, and in the second the intersection has dropped out of the formula entirely, replaced by an intersection of direction spaces and an apologetic $+1$. Eq. 21.6.1 has one case and needs no directions. That is the whole reason for building projective space, and everything the rest of this chapter does with it rests on this one line.

Corollary 21.6.7 — Two Lines in a Projective Plane Meet

Let P be a projective plane, that is $P = \mathbb{P}(V)$ with $\dim V = 3$. Then any two distinct lines of P meet in exactly one point.

Proof. Let $S = \mathbb{P}(U)$ and $T = \mathbb{P}(W)$ be distinct lines, so $\dim U = \dim W = 2$ and $U \neq W$ by Lemma 21.6.4. Then $U + W$ contains U properly: otherwise $W \subseteq U$, and two subspaces of the same dimension with one inside the other are equal (Theorem 1.6.8 applied inside U), contradicting $U \neq W$. So $\dim(U + W) \geq 3$, and $\dim(U + W) \leq \dim V = 3$, whence $\dim(U + W) = 3$ and $\dim(S \vee T) = 2$.

By Theorem 21.6.6,

$$\dim(S \cap T) = \dim S + \dim T - \dim(S \vee T) = 1 + 1 - 2 = 0,$$

and a projective subspace of dimension 0 is $\mathbb{P}(Y)$ with $\dim Y = 1$, which by Proposition 21.6.1 is a single point. This proves the corollary.

■

Proposition 21.6.8 — Two Points Determine a Line

Let $\mathbb{P}(V)$ be a projective space of dimension at least 1. Any two distinct points of $\mathbb{P}(V)$ lie on exactly one line.

Proof. Let $[\mathbf{x}] \neq [\mathbf{y}]$. Then $\mathbf{x}$ and $\mathbf{y}$ are linearly independent: a dependence relation with $\mathbf{x}, \mathbf{y} \neq \mathbf{0}$ would give $\mathbf{y} = \lambda \mathbf{x}$ with $\lambda \neq 0$, hence $[\mathbf{x}] = [\mathbf{y}]$. So $U = \operatorname{span}(\mathbf{x}, \mathbf{y})$ has

dimension 2 and $\mathbb{P}(U)$ is a line containing both points.

If $\mathbb{P}(Y)$ is any line containing both, then $\mathbf{x}, \mathbf{y} \in Y$ by Lemma 21.6.4, so $U \subseteq Y$; and $\dim Y = 2 = \dim U$, so $U = Y$ by Theorem 1.6.8. This proves the proposition.

■

The two statements just proved are each other's mirror images: "two distinct points lie on a unique line" and "two distinct lines meet in a unique point". Section 8 will show that this mirroring is not a coincidence.

Remark. The set $\mathbb{P}^2(\mathbb{R})$ is also a famous topological object, the real projective plane, and readers who have met it will be expecting words like "compact" and "non-orientable". This chapter does not use them. Nothing here is topological; every argument has been a statement about subspaces of a vector space, valid over any field, including finite ones where topology has nothing to say.

21.6.5 Counting points

Over a finite field the whole space can be counted, and the count is a useful check on the constructions above.

Proposition 21.6.9 — The Number of Points of a Finite Projective Space

Let F be a finite field with q elements and let $n \geq 0$. Then

$$|\mathbb{P}^n(F)| = 1 + q + q^2 + \cdots + q^n = \frac{q^{n+1} - 1}{q - 1}.$$

More generally a projective subspace of dimension d has $(q^{d+1} - 1)/(q - 1)$ points.

Idea. Count the non-zero vectors and divide by the size of one equivalence class. Every class has the same size, $q - 1$, because scaling a fixed non-zero vector by distinct scalars gives distinct vectors. The alternative count, chart by chart, gives the geometric sum directly, and the two agreeing is a check on Theorem 21.6.2.

Proof. A vector of F^{n+1} is a list of $n + 1$ entries, each chosen from F independently, so there are q^{n+1} of them and $q^{n+1} - 1$ non-zero ones.

Fix $\mathbf{x} \neq \mathbf{0}$. Its equivalence class is $\{\lambda\mathbf{x} : \lambda \in F, \lambda \neq 0\}$, and the map $\lambda \mapsto \lambda\mathbf{x}$ is injective there: if $\lambda\mathbf{x} = \mu\mathbf{x}$ then $(\lambda - \mu)\mathbf{x} = \mathbf{0}$, and $\mathbf{x} \neq \mathbf{0}$ forces $\lambda = \mu$. So every class has exactly $q - 1$ elements.

The classes partition $F^{n+1} \setminus \{\mathbf{0}\}$ (Theorem 0.5.2), so the number of classes is $(q^{n+1} - 1)/(q - 1)$. That this equals $1 + q + \cdots + q^n$ follows from

$$\begin{aligned}(q - 1)(1 + q + \cdots + q^n) &= (q + q^2 + \cdots + q^{n+1}) - (1 + q + \cdots + q^n) \\ &= q^{n+1} - 1,\end{aligned}$$

the middle terms canceling in pairs. For a projective subspace $\mathbb{P}(U)$ of dimension d,

the space U has dimension $d+1$, hence q^{d+1} elements, since a choice of basis puts it in bijection with F^{d+1} (Corollary 3.5.5); the same argument applies. This proves the proposition.

■

The geometric sum is Theorem 21.6.2 in disguise: the chart contributes q^n points and the hyperplane at infinity contributes $|\mathbb{P}^{n-1}(F)|$, so $|\mathbb{P}^n| = q^n + |\mathbb{P}^{n-1}|$, and unwinding that recursion from $|\mathbb{P}^0| = 1$ gives $1 + q + \cdots + q^n$.

Example. (The Fano plane)

Describe $\mathbb{P}^2(\mathbb{F}_2)$ completely: its points, its lines, how many points lie on each line and how many lines pass through each point. Verify Corollary 21.6.7 and Proposition 21.6.8 by direct count.

Solution. By Proposition 21.6.9 there are $1+2+4=7$ points. Since $\mathbb{F}_2^\times = \{1\}$, each point has a **unique** non-zero representative, so the points are simply the seven non-zero vectors of $\mathbb{F}_2^3$. Number the point $[x_0 : x_1 : x_2]$ by $4x_0 + 2x_1 + x_2$:

$$1 = [0{:}0{:}1], \quad 2 = [0{:}1{:}0], \quad 3 = [0{:}1{:}1], \quad 4 = [1{:}0{:}0],$$
$$5 = [1{:}0{:}1], \quad 6 = [1{:}1{:}0], \quad 7 = [1{:}1{:}1].$$

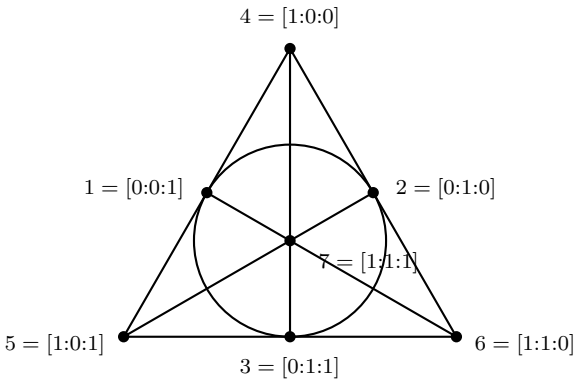
A line is $\mathbb{P}(U)$ with $\dim U = 2$, and by Proposition 21.6.9 it has $(2^2-1)/(2-1) = 3$ points. Since $U = \{\mathbf{0}, \mathbf{u}, \mathbf{w}, \mathbf{u}+\mathbf{w}\}$ for any two distinct non-zero $\mathbf{u}, \mathbf{w} \in U$, the lines are exactly the triples $\{\mathbf{u}, \mathbf{w}, \mathbf{u}+\mathbf{w}\}$ of non-zero vectors. There are seven:

$$\{1,2,3\} : x_0 = 0, \qquad \{1,4,5\} : x_1 = 0,$$
$$\{2,4,6\} : x_2 = 0, \qquad \{1,6,7\} : x_0 + x_1 = 0,$$
$$\{2,5,7\} : x_0 + x_2 = 0, \qquad \{3,4,7\} : x_1 + x_2 = 0,$$
$$\{3,5,6\} : x_0 + x_1 + x_2 = 0.$$

Each is the kernel of one of the seven non-zero linear functionals on $\mathbb{F}_2^3$, and different functionals have different kernels here because a functional is determined up to a non-zero scalar by its kernel — if $\ker\varphi = \ker\psi = U$ with $\dim U = 2$, then φ and ψ both vanish on U and so lie in the annihilator U^0 (Definition 4.2.1), which has dimension $3-2=1$ by Theorem 4.2.2 — and the only non-zero scalar here is 1. So there are exactly seven lines.

Incidences. Each of the seven labels appears in exactly three of the seven displayed triples, so every point lies on exactly 3 lines. The total is consistent: counting incident pairs (point, line through it) by lines gives $7 \cdot 3 = 21$, and counting them by points gives $7 \cdot 3 = 21$ as well.

The two theorems. There are $\binom{7}{2} = 21$ pairs of points, and each of the 7 lines contains $\binom{3}{2} = 3$ pairs, for 21 pairs in total; since no pair can be covered twice without two lines sharing two points — which Proposition 21.6.8 forbids — each pair is covered exactly once. Dually there are $\binom{7}{2} = 21$ pairs of lines, and each of the 7 points lies on 3 lines and so accounts for $\binom{3}{2} = 3$ of those pairs, again 21 in total; no pair of lines is accounted for twice, since two points on both lines would again contradict Proposition 21.6.8. So every pair of lines meets in exactly one point, as Corollary 21.6.7 says.



the Fano plane $\mathbb{P}^2(\mathbb{F}_2)$: 7 points, 7 lines
(three sides, three medians, one circle), 3 points on each line

In the picture the "midpoint" of two marked points really is their sum: $4 + 5 = [0{:}0{:}1] = 1$, and likewise all round. The circle is the line $x_0 = 0$, which under Theorem 21.6.2 is the line at infinity, so the picture also shows $\mathbb{P}^2(\mathbb{F}_2)$ as the four affine points $4, 5, 6, 7$ of $\mathbb{F}_2^2$ together with the three directions $1, 2, 3$.

Warning. **A drawing of a finite projective plane is a mnemonic, not a picture.** The seven points of the Fano plane are not points of the Euclidean plane, and the "circle" is a line, not a curve. The only content of the drawing is the incidence data: which triples of the seven labels form a line. Any picture with the same seven triples is the same object, and no metric statement about the drawing means anything.

21.6.6 Exercises

21.6.6.1 A. Check your understanding

Exercise A1.

(a) State Definition 21.6.1, and say why $\mathbf{0}$ is removed before taking the quotient.

(b) What is $\dim \mathbb{P}(V)$ when $\dim V = 5$? What is the dimension of a hyperplane of that projective space, and of what subspace of V is it the image?

(c) Decide whether $[2 : 4 : 6] = [1 : 2 : 3]$ in $\mathbb{P}^2(\mathbb{Q})$, and whether $[0 : 1] = [0 : 2]$ in $\mathbb{P}^1(\mathbb{F}_3)$. Justify your answers.

(d) True or false: the condition $x_1 + x_2 = 1$ defines a subset of $\mathbb{P}^2(\mathbb{R})$. Justify your answer.

(e) How many points does $\mathbb{P}^3(\mathbb{F}_5)$ have?

Solution.

(a) $\mathbb{P}(V) = (V \setminus \{\mathbf{0}\})/\!\sim$ with $\mathbf{x} \sim \mathbf{y}$ when $\mathbf{y} = \lambda\mathbf{x}$ for some non-zero λ, and $\dim \mathbb{P}(V) = \dim V - 1$. The vector $\mathbf{0}$ is removed because its class is $\{\mathbf{0}\}$ alone, so it would contribute one point whose span $\operatorname{span}(\mathbf{0}) = \{\mathbf{0}\}$ is the zero subspace and not a line, and Proposition 21.6.1 would fail.

(b) $\dim \mathbb{P}(V) = 4$. A hyperplane has dimension 3 and is $\mathbb{P}(U)$ for a subspace U of V with $\dim U = 4$.

(c) Yes: $(2,4,6) = 2\,(1,2,3)$ and $2 \neq 0$ in $\mathbb{Q}$. Yes again: $(0,2) = 2\,(0,1)$ and $2 \neq 0$ in $\mathbb{F}_3$.

(d) False. The expression is not homogeneous: $(1,1,0)$ satisfies it but $(2,2,0)$, which represents the same point, does not. Only the vanishing of a homogeneous expression is a condition on points.

(e) $(5^4 - 1)/(5 - 1) = 624/4 = 156$, by Proposition 21.6.9.

21.6.6.2 B. Practice

Exercise B1: Meeting at infinity.

In $\mathbb{P}^2(\mathbb{R})$, complete each pair of affine lines and find their intersection point, saying in each case whether it lies in the chart U_0 or at infinity.

(a) $y_2 = 2y_1 + 1$ and $y_2 = 2y_1 - 3$.

(b) $y_2 = 2y_1 + 1$ and $y_1 + y_2 = 4$.

(c) $y_1 = 5$ and $y_1 = -2$.

Solution.

(a) Writing them as $2y_1 - y_2 = -1$ and $2y_1 - y_2 = 3$, Proposition 21.6.3 gives $\bar{L}_1 : 2x_1 - x_2 + x_0 = 0$ and $\bar{L}_2 : 2x_1 - x_2 - 3x_0 = 0$. Subtracting, $4x_0 = 0$, so $x_0 = 0$ and $x_2 = 2x_1$: the point $[0:1:2]$, at infinity. This agrees with part (c) of that proposition, since $(a_1, a_2) = (2, -1)$ gives $[0:1:2]$.

(b) Here $\bar{L}_1 : 2x_1 - x_2 + x_0 = 0$ and $\bar{L}_2 : x_1 + x_2 - 4x_0 = 0$. Adding, $3x_1 - 3x_0 = 0$, so $x_1 = x_0$; then $x_2 = 4x_0 - x_1 = 3x_0$. Taking $x_0 = 1$ gives $[1:1:3]$, which lies in U_0 and corresponds to the affine point $(1,3)$. Check: $3 = 2 \cdot 1 + 1$ and $1 + 3 = 4$.

(c) $\bar{L}_1 : x_1 - 5x_0 = 0$ and $\bar{L}_2 : x_1 + 2x_0 = 0$. Subtracting, $7x_0 = 0$, so $x_0 = 0$ and then $x_1 = 0$, forcing $x_2 \neq 0$: the point $[0:0:1]$, at infinity, the vertical direction.

Exercise B2: Joins and meets.

In $\mathbb{P}^4(F)$, let S be a plane and T a plane.

(a) What are the possible values of $\dim(S \cap T)$? Justify each.

(b) Show that two planes in $\mathbb{P}^4(F)$ always meet.

(c) Give an example in $\mathbb{P}^5(F)$ of two planes that do not meet.

Solution. Throughout, $S = \mathbb{P}(U)$ and $T = \mathbb{P}(W)$ with $\dim U = \dim W = 3$ inside a space of dimension 5 (for $\mathbb{P}^4$).

(a) By Theorem 21.6.6, $\dim(S \cap T) = 4 - \dim(S \vee T)$. Now $S \vee T$ contains S, so $\dim(S \vee T) \geq 2$, and it is contained in $\mathbb{P}^4$, so $\dim(S \vee T) \leq 4$. Hence $\dim(S \cap T) \in \{0, 1, 2\}$, and all three occur: 2 when $S = T$; 1 when $U \cap W$ has dimension 2, for instance $U = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3)$, $W = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_4)$; and 0 for $U = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3)$, $W = \operatorname{span}(\mathbf{e}_3, \mathbf{e}_4, \mathbf{e}_5)$.

(b) The computation in (a) shows $\dim(S \cap T) \geq 4 - 4 = 0 > -1$, so $S \cap T \neq \emptyset$.

(c) In $\mathbb{P}^5(F) = \mathbb{P}(F^6)$ take $U = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3)$ and $W = \operatorname{span}(\mathbf{e}_4, \mathbf{e}_5, \mathbf{e}_6)$. Then

$U \cap W = \{\mathbf{0}\}$, so $S \cap T = \mathbb{P}(\{\mathbf{0}\}) = \emptyset$, and indeed Theorem 21.6.6 gives $\dim(S \vee T) + (-1) = 2 + 2$, that is $\dim(S \vee T) = 5$, the whole space.

Exercise B3: A projective plane over three elements.

Let $F = \mathbb{F}_3$.

(a) How many points does $\mathbb{P}^2(\mathbb{F}_3)$ have, and how many lines?

(b) How many points lie on each line, and how many lines pass through each point?

(c) List the four points of the line $x_0 = 0$.

Solution.

(a) By Proposition 21.6.9, $|\mathbb{P}^2(\mathbb{F}_3)| = 1 + 3 + 9 = 13$. A line is $\mathbb{P}(U)$ with $\dim U = 2$, equivalently the kernel of a non-zero functional on $\mathbb{F}_3^3$, and two non-zero functionals have the same kernel exactly when they are proportional (Corollary 4.6.6 applied to the 1×3 matrices, or directly: a kernel of dimension 2 determines the functional up to scale). So the lines correspond to the points of $\mathbb{P}((\mathbb{F}_3^3)^*)$, of which there are again 13.

(b) Each line has $(3^2 - 1)/(3 - 1) = 4$ points. For the lines through a fixed point $[\mathbf{x}]$: they are the $\mathbb{P}(U)$ with $\operatorname{span}(\mathbf{x}) \subseteq U$ and $\dim U = 2$, and every such U is $\operatorname{span}(\mathbf{x}, \mathbf{y})$ for one of the $3^3 - 3 = 24$ vectors $\mathbf{y} \notin \operatorname{span}(\mathbf{x})$, while two choices $\mathbf{y}, \mathbf{y}'$ give the same U exactly when $\mathbf{y}' \in U \setminus \operatorname{span}(\mathbf{x})$, a set of $3^2 - 3 = 6$ vectors. So each point lies on $24/6 = 4$ lines. (Consistently, the incident pairs number $13 \cdot 4 = 52$ counted by lines and $13 \cdot 4 = 52$ counted by points.)

(c) The points with $x_0 = 0$ are $[0 : x_1 : x_2]$ with $(x_1, x_2) \neq (0, 0)$, that is the points of $\mathbb{P}^1(\mathbb{F}_3)$: $[0 : 1 : 0]$, $[0 : 1 : 1]$, $[0 : 1 : 2]$ and $[0 : 0 : 1]$. Four points, as (b) requires.

21.6.6.3 C. Going deeper

Exercise C1: Other charts.

Work in $\mathbb{P}^n(F)$ and fix $j \in \{0, 1, \ldots, n\}$. Let $U_j = \{[\mathbf{x}] : x_j \neq 0\}$.

(a) Prove that U_j is well defined and in bijection with F^n.

(b) Prove that $U_0 \cup U_1 \cup \cdots \cup U_n = \mathbb{P}^n(F)$.

(c) For $n = 1$ and $F = \mathbb{R}$, describe the point of U_1 that is missing from U_0, and the point of U_0 missing from U_1. Conclude that the "point at infinity" is not a property of a point, but of a chart.

Solution.

(a) Both parts repeat Theorem 21.6.2 with the index 0 replaced by j. Scaling multiplies x_j by a non-zero scalar, so the condition $x_j \neq 0$ is independent of the representative. The bijection is

$$(a_1, \ldots, a_n) \mapsto [a_1 : \cdots : a_j : 1 : a_{j+1} : \cdots : a_n],$$

with the 1 in position j; it is injective because comparing the j-th entries of

two proportional representatives forces the scalar to be 1, and surjective because $[\mathbf{x}] = [x_j^{-1}\mathbf{x}]$ when $x_j \neq 0$.

(b) A point is $[\mathbf{x}]$ with $\mathbf{x} \neq \mathbf{0}$, so some coordinate x_j is non-zero, and then $[\mathbf{x}] \in U_j$.

(c) $\mathbb{P}^1(\mathbb{R}) = \{[1 : a] : a \in \mathbb{R}\} \cup \{[0 : 1]\}$. The chart U_0 omits exactly $[0 : 1]$, and the chart $U_1 = \{[b : 1] : b \in \mathbb{R}\} \cup \{[1 : 0]\}$ omits exactly $[1 : 0]$. Both omitted points are perfectly ordinary points of $\mathbb{P}^1(\mathbb{R})$; each is at infinity for one chart and in the affine part of the other. So "at infinity" describes a relation between a point and a chosen chart, not the point itself.

Exercise C2: Counting subspaces.

Let F be a finite field with q elements.

(a) Prove that the number of lines in $\mathbb{P}^2(F)$ equals the number of points, namely $q^2 + q + 1$. *Hint: a line is the kernel of a non-zero functional.*

(b) Deduce that every point of $\mathbb{P}^2(F)$ lies on exactly $q + 1$ lines.

(c) How many points does a hyperplane of $\mathbb{P}^n(F)$ have, and how many points of $\mathbb{P}^n(F)$ lie outside it?

Solution.

(a) A line of $\mathbb{P}^2(F)$ is $\mathbb{P}(U)$ with $\dim U = 2$, and by Lemma 4.6.1 such a U is the kernel of a non-zero functional φ on F^3, since $\dim U^0 = 3 - 2 = 1$ (Theorem 4.2.2) and U is the common kernel of its annihilator. Two non-zero functionals have the same kernel exactly when they are proportional: if $\ker \varphi = \ker \psi = U$, then φ and ψ both lie in the 1-dimensional space U^0, so one is a scalar multiple of the other, and the scalar is non-zero. So lines correspond to points of $\mathbb{P}((F^3)^*)$, and $(F^3)^*$ has dimension 3 (Corollary 4.1.4); by Proposition 21.6.9 there are $q^2 + q + 1$ of them.

(b) Count incident pairs (point, line through it) in two ways. Each line has $q+1$ points by Proposition 21.6.9, so the count is $(q^2+q+1)(q+1)$. By symmetry among the q^2+q+1 points — or simply dividing — each point lies on $(q^2+q+1)(q+1)/(q^2+q+1) = q+1$ lines, provided every point lies on the same number. That last point needs an argument. The lines through a fixed $[\mathbf{x}]$ are the $\mathbb{P}(U)$ with $\operatorname{span}(\mathbf{x}) \subseteq U$ and $\dim U = 2$, and every such U is $\operatorname{span}(\mathbf{x}, \mathbf{y})$ for some $\mathbf{y} \notin \operatorname{span}(\mathbf{x})$, of which there are $q^3 - q$. Two choices $\mathbf{y}, \mathbf{y}'$ give the same U exactly when $\mathbf{y}' \in U \setminus \operatorname{span}(\mathbf{x})$, a set of $q^2 - q$ vectors. So the number of such U is $(q^3 - q)/(q^2 - q) = q + 1$, independently of $[\mathbf{x}]$.

(c) A hyperplane is $\mathbb{P}(U)$ with $\dim U = n$, so it has $(q^n - 1)/(q - 1) = 1 + q + \cdots + q^{n-1}$ points. Subtracting from $1 + q + \cdots + q^n$ leaves q^n points outside, in agreement with Theorem 21.6.2, whose chart U_0 is exactly the complement of a hyperplane and is in bijection with F^n.

Exercise C3: Where the affine formula goes wrong.

Let A and B be flats of $\mathbb{A}^3(F)$.

(a) Give two lines in $\mathbb{A}^3(F)$ that do not meet and are not parallel, and compute $\dim(A \vee B)$ from Theorem 21.2.4.

(b) Complete both lines to projective lines in $\mathbb{P}^3(F)$ by the recipe of Theorem 21.6.2, that is by adding the points with $x_0 = 0$ to the projective subspace each spans, and verify Eq. 21.6.1 for the completed pair.

(c) Explain in one sentence why the projective formula could not have an exceptional case, given Proposition 21.6.5.

Solution.

(a) Take $A = \{(t, 0, 0) : t \in F\}$ and $B = \{(0, s, 1) : s \in F\}$. A common point would need third coordinate 0 and 1, so $A \cap B = \emptyset$. Their direction spaces are $\operatorname{span}(\mathbf{e}_1)$ and $\operatorname{span}(\mathbf{e}_2)$, which are different, so they are not parallel and $\vec{A} \cap \vec{B} = \{\mathbf{0}\}$. The second case of Theorem 21.2.4 (c) gives $\dim(A \vee B) = 1 + 1 - 0 + 1 = 3$, the whole of $\mathbb{A}^3(F)$.

(b) Under ι of Theorem 21.6.2, A becomes $\{[1 : t : 0 : 0]\}$, whose points together with $[0 : 1 : 0 : 0]$ form $\mathbb{P}(U)$ with $U = \operatorname{span}\big((1, 0, 0, 0), (0, 1, 0, 0)\big)$; and B becomes $\{[1 : 0 : s : 1]\}$, giving $\mathbb{P}(W)$ with $W = \operatorname{span}\big((1, 0, 0, 1), (0, 0, 1, 0)\big)$. Now $U \cap W = \{\mathbf{0}\}$: a vector of U has third and fourth entries 0, while a vector $a(1, 0, 0, 1) + b(0, 0, 1, 0)$ of W has third entry b and fourth entry a, so both a and b vanish. Hence $S \cap T = \emptyset$ of dimension -1, and $U + W$ has dimension $2 + 2 - 0 = 4$, so $\dim(S \vee T) = 3$. Then $3 + (-1) = 1 + 1$, as Eq. 21.6.1 requires. The two projective lines still do not meet, which is correct: Corollary 21.6.7 is about a projective **plane**, and these lines do not lie in one.

(c) Because by Proposition 21.6.5 both the meet and the join of projective subspaces are again projective subspaces, coming from $U \cap W$ and $U + W$, and the vector-space formula Theorem 1.7.3 holds for those with no hypothesis whatever, the empty intersection being simply the case $U \cap W = \{\mathbf{0}\}$.

21.7 Projective Transformations

Section 06 built $\mathbb{P}(V)$ out of the lines through the origin of V, and a construction is only as good as the maps that go with it. Here the maps are already in hand: an invertible linear operator sends lines through the origin to lines through the origin, so it permutes the points of $\mathbb{P}(V)$. This section shows that two operators give the same permutation exactly when they differ by a non-zero scalar, that such a map is pinned down by its values on $n+2$ points in general position — and, over any field with more than two elements, **not** on $n + 1$ — and that the failure at $n + 1$ is precisely what makes the cross-ratio of four points on a line a genuine invariant.

Throughout, F is an arbitrary field and V, W are finite-dimensional vector spaces over F. Nothing in this section needs a characteristic assumption, an ordering or an inner product. In F^{n+1} we index coordinates from 0, writing $\mathbf{x} = (x_0, x_1, \dots, x_n)$ and $\mathbf{e}_0, \dots, \mathbf{e}_n$ for the standard basis, so that homogeneous coordinates read $[x_0 : x_1 : \cdots : x_n]$ as in Definition 21.6.2. We write $F^\times = F \setminus \{0\}$ for the multiplicative group of F (Example (Groups)), and $\mathrm{GL}(V)$ for the set of invertible linear operators $V \to V$; composition makes $\mathrm{GL}(V)$ a group (Definition 0.10.1), with identity id_V, exactly as it makes $\mathrm{GL}_n(F)$ one.

21.7.1 Maps induced by linear isomorphisms

We need maps $\mathbb{P}(V) \to \mathbb{P}(W)$, and the only structure a projective space has is its supply of points, that is, of one-dimensional subspaces (Definition 21.6.1). So we want maps that carry one-dimensional subspaces to one-dimensional subspaces. A linear map T does this as soon as it kills nothing: $T(\operatorname{span}(\mathbf{x})) = \operatorname{span}(T\mathbf{x})$, and the right-hand side is a line precisely when $T\mathbf{x} \neq \mathbf{0}$.

A projective transformation is an invertible linear map, read on lines instead of on vectors.

Definition 21.7.1 — Projective Transformation

Let $T\colon V \to W$ be an **isomorphism** of vector spaces over F. The **projective transformation**, or **projectivity**, induced by T is the map

$$[T]\colon \mathbb{P}(V) \to \mathbb{P}(W), \qquad [T]\big([\mathbf{x}]\big) \coloneqq [T\mathbf{x}].$$

A map $\mathbb{P}(V) \to \mathbb{P}(W)$ is a projectivity if it equals $[T]$ for **some** isomorphism T.

Two things must be checked before the formula means anything, and both use invertibility. First, $[T\mathbf{x}]$ has to be a point at all: a point of $\mathbb{P}(W)$ is $[\mathbf{w}]$ for a **non-zero** $\mathbf{w}$, and if $\mathbf{x} \neq \mathbf{0}$ then $T\mathbf{x} \neq \mathbf{0}$, because T is injective (Theorem 3.2.3). Second, the recipe must not depend on the representative: if $[\mathbf{x}] = [\mathbf{y}]$, then $\mathbf{y} = \lambda\mathbf{x}$ for some $\lambda \in F^\times$ (Definition 21.6.2), so $T\mathbf{y} = \lambda\, T\mathbf{x}$ and $[T\mathbf{y}] = [T\mathbf{x}]$.

Proposition 21.7.1 — Projectivities Compose and Invert

Let $T\colon V \to W$ and $S\colon W \to X$ be isomorphisms of finite-dimensional vector spaces over F. Then $[S] \circ [T] = [ST]$, the map $[T]$ is a bijection with inverse $[T^{-1}]$, and $[\mathrm{id}_V] = \mathrm{id}_{\mathbb{P}(V)}$.

Proof. For $\mathbf{x} \in V$ with $\mathbf{x} \neq \mathbf{0}$, $\big([S] \circ [T]\big)([\mathbf{x}]) = [S(T\mathbf{x})] = [(ST)\mathbf{x}] = [ST]([\mathbf{x}])$, and ST is an isomorphism as a composition of isomorphisms (Theorem 3.5.3). Taking $S = T^{-1}$ gives $[T^{-1}] \circ [T] = [\mathrm{id}_V]$, and $[\mathrm{id}_V]([\mathbf{x}]) = [\mathbf{x}]$, so $[\mathrm{id}_V] = \mathrm{id}_{\mathbb{P}(V)}$; taking the composition in the other order gives $[T] \circ [T^{-1}] = \mathrm{id}_{\mathbb{P}(W)}$. Hence $[T]$ is a bijection with inverse $[T^{-1}]$. ∎

Examples. Take $V = W = F^{n+1}$, so that a projectivity of $\mathbb{P}^n(F)$ is $[\mathbf{x}] \mapsto [\mathbf{A}\mathbf{x}]$ for an invertible $\mathbf{A} \in \mathrm{GL}_{n+1}(F)$.

- $\mathbf{A} = \mathbf{I}_{n+1}$ gives the identity, and so does $\mathbf{A} = \lambda\mathbf{I}_{n+1}$ for any $\lambda \neq 0$, since $[\lambda\mathbf{x}] = [\mathbf{x}]$. This degenerate case is the whole content of the next subsection.
- On $\mathbb{P}^1(F)$, the matrix $\mathbf{A} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ sends $[x_0 : x_1]$ to $[x_1 : x_0]$. In the chart $x_1 \neq 0$, where $[t : 1]$ is the scalar t, this is $t \mapsto 1/t$ for $t \neq 0$, and it exchanges $[1 : 0]$ with $[0 : 1]$. A projectivity repairs the one defect of $t \mapsto 1/t$: on the projective line there is no missing value.
- On $\mathbb{P}^2(F)$, a permutation matrix permutes the three coordinate points $[1 : 0 : 0]$, $[0 : 1 : 0]$, $[0 : 0 : 1]$.

Non-example by minimal change. Drop invertibility. On $\mathbb{P}^1(F)$ put $\mathbf{A} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. For $[1:0]$ the recipe gives $[1:0]$, which is fine; but $\mathbf{A}(0,1) = (0,0)$, and $[\mathbf{0}]$ is not a point of $\mathbb{P}^1(F)$. The formula fails on exactly the points of $\mathbb{P}(\ker \mathbf{A})$, and injectivity is the clause that rules them out. The recipe does still make sense on the remaining points $[1:t]$, but it is no longer injective there: $\mathbf{A}(1,t) = (1,0)$ for every t, so all of them go to the single point $[1:0]$.

Projectivities respect everything $\mathbb{P}(V)$ is made of.

Proposition 21.7.2 — Projectivities Preserve Subspaces, Joins and Meets

Let $T\colon V \to W$ be an isomorphism and let U be a subspace of V. Then

$$[T]\big(\mathbb{P}(U)\big) = \mathbb{P}(T(U)),$$

a projective subspace of $\mathbb{P}(W)$ of the same dimension as $\mathbb{P}(U)$, and the restriction of $[T]$ to $\mathbb{P}(U)$ is the projectivity induced by the isomorphism $T|_U\colon U \to T(U)$. Consequently $[T]$ preserves inclusion, intersections and joins of projective subspaces.

Proof. By Definition 21.6.3, $\mathbb{P}(U) = \{[\mathbf{u}] : \mathbf{u} \in U,\ \mathbf{u} \neq \mathbf{0}\}$ and $\dim \mathbb{P}(U) = \dim U - 1$. A point of $[T](\mathbb{P}(U))$ is $[T\mathbf{u}]$ with $\mathbf{0} \neq \mathbf{u} \in U$, and these are exactly the points $[\mathbf{w}]$ with $\mathbf{0} \neq \mathbf{w} \in T(U)$, since T is a bijection from U onto $T(U)$. Hence $[T](\mathbb{P}(U)) = \mathbb{P}(T(U))$. The restriction $T|_U$ is linear and injective with image $T(U)$, hence an isomorphism onto $T(U)$, so $\dim T(U) = \dim U$ (Theorem 3.5.4) and the two projective subspaces have equal dimension; and $[T|_U]$ agrees with $[T]$ on $\mathbb{P}(U)$ by the same formula.

For the last sentence, T preserves inclusion of subspaces and satisfies $T(U_1 \cap U_2) = T(U_1) \cap T(U_2)$ and $T(U_1 + U_2) = T(U_1) + T(U_2)$, the first because T is injective and the second because T is linear and surjective onto its image. Passing to projective subspaces, inclusion transfers in both directions by Lemma 21.6.4, intersections by Proposition 21.6.5 (a) and joins by Proposition 21.6.5 (b), in each case applied on both sides of T.

■

21.7.2 The projective linear group

Different matrices can induce the same projectivity: $\mathbf{I}_2$ and $2\mathbf{I}_2$ both act as the identity on $\mathbb{P}^1(\mathbb{Q})$. The next theorem says that this is the only way it happens, and it is the reason the group of projectivities is smaller than GL.

Theorem 21.7.3 — Projectivities and Scalars

Let $\dim V = \dim W \geq 1$ and let $S, T\colon V \to W$ be isomorphisms.

(a) $[S] = [T]$ if and only if $S = \lambda T$ for some $\lambda \in F^\times$.

(b) The set $\mathrm{PGL}(V) \coloneqq \{[T] : T \in \mathrm{GL}(V)\}$ of projectivities of $\mathbb{P}(V)$ is a group under composition, the **projective linear group** of V.

(c) The map $\Pi\colon \mathrm{GL}(V) \to \mathrm{PGL}(V)$, $T \mapsto [T]$, is a surjective group homomorphism, and $\ker \Pi = \{\lambda \operatorname{id}_V : \lambda \in F^\times\}$.

For $V = F^{n+1}$ we write $\mathrm{PGL}_{n+1}(F)$ for $\mathrm{PGL}(F^{n+1})$; part (a) then says that $\mathbf{A}, \mathbf{B} \in \mathrm{GL}_{n+1}(F)$ induce the same projectivity of $\mathbb{P}^n(F)$ exactly when $\mathbf{B} = \lambda\mathbf{A}$ for some $\lambda \neq 0$.

Idea. One direction is the computation $[\lambda T\mathbf{x}] = [T\mathbf{x}]$. For the other, put $R = T^{-1}S$, so that the hypothesis says $[R\mathbf{x}] = [\mathbf{x}]$ for every $\mathbf{x} \neq \mathbf{0}$: **every non-zero vector is an eigenvector of** R. That is far stronger than it looks. Test it on $\mathbf{x}$, $\mathbf{y}$ and $\mathbf{x}+\mathbf{y}$: if $\mathbf{x}$ and $\mathbf{y}$ are independent, comparing coefficients forces their eigenvalues to agree, and if they are dependent, the eigenvalue is forced directly. So R is a scalar. Parts (b) and (c) are then bookkeeping with Proposition 21.7.1.

Proof.

(a) ($\Leftarrow$) If $S = \lambda T$ with $\lambda \neq 0$, then for every $\mathbf{x} \neq \mathbf{0}$ we have $S\mathbf{x} = \lambda(T\mathbf{x})$, so $[S\mathbf{x}] = [T\mathbf{x}]$ by Definition 21.6.2. Hence $[S] = [T]$.
($\Rightarrow$) Suppose $[S] = [T]$. Put $R = T^{-1}S \in \mathrm{GL}(V)$. For every $\mathbf{x} \neq \mathbf{0}$, $[S\mathbf{x}] = [T\mathbf{x}]$ gives $S\mathbf{x} = \mu T\mathbf{x}$ for some $\mu \in F^\times$, hence $R\mathbf{x} = T^{-1}S\mathbf{x} = \mu\mathbf{x}$. So for each $\mathbf{x} \neq \mathbf{0}$ there is a scalar $\lambda_{\mathbf{x}} \in F^\times$ with $R\mathbf{x} = \lambda_{\mathbf{x}}\mathbf{x}$.
We show $\lambda_{\mathbf{x}}$ does not depend on $\mathbf{x}$. Let $\mathbf{x}, \mathbf{y} \neq \mathbf{0}$.
Case 1: $(\mathbf{x}, \mathbf{y})$ *is dependent.* Take a dependence $s\mathbf{x} + t\mathbf{y} = \mathbf{0}$ with s, t not both zero. If $t = 0$ then $s \neq 0$ and $\mathbf{x} = \mathbf{0}$, which is false; so $t \neq 0$ and $\mathbf{y} = c\mathbf{x}$ with $c = -s/t$, and $c \neq 0$ because $\mathbf{y} \neq \mathbf{0}$. Then

$$\lambda_{\mathbf{y}}\mathbf{y} = R\mathbf{y} = cR\mathbf{x} = c\lambda_{\mathbf{x}}\mathbf{x} = \lambda_{\mathbf{x}}\mathbf{y},$$

and $\mathbf{y} \neq \mathbf{0}$ gives $\lambda_{\mathbf{y}} = \lambda_{\mathbf{x}}$.
Case 2: $(\mathbf{x}, \mathbf{y})$ *is independent.* Then $\mathbf{x}+\mathbf{y} \neq \mathbf{0}$, and

$$\lambda_{\mathbf{x}+\mathbf{y}}\mathbf{x} + \lambda_{\mathbf{x}+\mathbf{y}}\mathbf{y} = R(\mathbf{x}+\mathbf{y}) = R\mathbf{x} + R\mathbf{y} = \lambda_{\mathbf{x}}\mathbf{x} + \lambda_{\mathbf{y}}\mathbf{y}.$$

Independence lets us compare coefficients, giving $\lambda_{\mathbf{x}} = \lambda_{\mathbf{x}+\mathbf{y}} = \lambda_{\mathbf{y}}$.
So there is one scalar $\lambda \in F^\times$ with $R\mathbf{x} = \lambda\mathbf{x}$ for all $\mathbf{x} \neq \mathbf{0}$, and also for $\mathbf{x} = \mathbf{0}$. Hence $R = \lambda \operatorname{id}_V$ and $S = TR = \lambda T$.

(b) By Proposition 21.7.1, $\mathrm{PGL}(V)$ is closed under composition and under inverses and contains $\operatorname{id}_{\mathbb{P}(V)} = [\operatorname{id}_V]$; composition of maps is associative. So (G1)–(G3) of Definition 0.10.1 hold.

(c) Surjectivity is the definition of $\mathrm{PGL}(V)$, and $\Pi(ST) = [ST] = [S][T] = \Pi(S)\Pi(T)$ by Proposition 21.7.1, so Π is a homomorphism (Definition 0.10.3). Its kernel is $\{T : [T] = [\operatorname{id}_V]\}$, which by (a) is $\{\lambda \operatorname{id}_V : \lambda \in F^\times\}$. This proves the theorem.

■

Remark. Part (c) is the sentence "$\mathrm{PGL}(V)$ is $\mathrm{GL}(V)$ modulo scalars", made precise without quotient groups, which this book has not built. By (a), the fiber of Π over $[T]$ is $\{\lambda T : \lambda \in F^\times\}$, and the fibers of any map partition its domain. The picture is the one Chapter 3 drew for the cosets $\mathbf{v} + U$ of Definition 3.9.2, with multiplication in place of addition and Lemma 3.9.3 replaced by part (a) above.

Warning. **A projectivity has no determinant, no trace and no eigenvalues.** Only a matrix has those, and a projectivity of $\mathbb{P}^n(F)$ is a matrix only up to a scalar. On $\mathbb{P}^2(\mathbb{Q})$, the matrices $\mathbf{I}_3$ and $2\mathbf{I}_3$ induce the same projectivity but have determinants 1 and 8, and traces 3 and 6. In general $\det(\lambda\mathbf{A}) = \lambda^{n+1}\det\mathbf{A}$, so the most one can hope to define is $\det\mathbf{A}$ modulo $(n+1)$-th powers. What **is** well defined is a fixed point: $[\mathbf{Ax}] = [\mathbf{x}]$ says $\mathbf{x}$ is an eigenvector of $\mathbf{A}$, and being an eigenvector does not depend on scaling $\mathbf{A}$.

21.7.3 Frames, and how many points pin a projectivity down

A linear map is determined by its values on a basis. A projectivity of $\mathbb{P}^n(F)$ is induced by an $(n+1)\times(n+1)$ matrix, which has $n+1$ columns, so the first guess is that $n+1$ points should determine it. Over any field with more than two elements the guess is wrong — the two-element field is a genuine exception, and we return to it below — and the reason is visible in Theorem 21.7.3: knowing $[\mathbf{Ae}_i]$ fixes each column of $\mathbf{A}$ only up to its own scalar, which leaves $n+1$ unknown scalars, while changing $\mathbf{A}$ to $\lambda\mathbf{A}$ costs only one. One extra point supplies the missing information.

First, the hypothesis under which the extra point helps.

Definition 21.7.2 — General Position

Let $\dim V = n+1$. A list $P_1,\dots,P_m$ of points of $\mathbb{P}(V)$ is **in general position** if for **every** subset $I \subseteq \{1,\dots,m\}$ with $|I| \le n+1$, and any choice of representatives $\mathbf{v}_i$ with $P_i = [\mathbf{v}_i]$, the list $(\mathbf{v}_i)_{i\in I}$ is linearly independent.

The clause "any choice of representatives" costs nothing: replacing $\mathbf{v}_i$ by $c_i\mathbf{v}_i$ with $c_i \neq 0$ does not change whether a list is independent, so the condition may be tested on one choice. For $m = n+2$, which is the case we need, general position says exactly that **every $n+1$ of the points have independent representatives**; no subset of size $n+2$ can be independent in an $(n+1)$-dimensional space, which is why the bound $|I| \le n+1$ is there.

Examples. In $\mathbb{P}^2(F)$, the four points $[1:0:0]$, $[0:1:0]$, $[0:0:1]$, $[1:1:1]$ are in general position: the first three representatives form a basis, and any three of the four are independent, since each of the other three triples has determinant ±1. In $\mathbb{P}^1(F)$, general position for three points means simply that they are pairwise distinct. The same holds in every dimension: the $n+2$ points $[\mathbf{e}_0],\dots,[\mathbf{e}_n]$, $[1:\cdots:1]$ of $\mathbb{P}^n(F)$ are in general position. Indeed $n+1$ of the representatives $\mathbf{e}_0,\dots,\mathbf{e}_n,(1,\dots,1)$ are either the $\mathbf{e}_i$ themselves, with determinant 1, or all of them but one, say $\mathbf{e}_j$, together with $(1,\dots,1)$; in that matrix row j is zero except for the entry 1 in the last column, and expanding along row j leaves the determinant of a permutation matrix, so the value is ±1. In $\mathbb{P}^n(F)$, a single point is always in general position, since one non-zero vector is independent.

Non-example by minimal change. Replace $[1:1:1]$ by $[1:1:0]$. The list $[1:0:0]$, $[0:1:0]$, $[0:0:1]$, $[1:1:0]$ fails: the subset $\{1,2,4\}$ has representatives $(1,0,0)$, $(0,1,0)$, $(1,1,0)$, and the third is the sum of the first two. Geometrically, three of the four points are collinear. No projectivity carries the first list to this one: a projectivity preserves joins and

their dimensions (Proposition 21.7.2), and here $[1:0:0] \vee [0:1:0] \vee [1:1:0]$ is a line, while $[1:0:0] \vee [0:1:0] \vee [1:1:1]$ is the whole plane.

The key step is that general position lets us choose representatives once and for all.

Lemma 21.7.4 — Normalizing a Frame

Let $\dim V = n+1 \geq 1$ and let $P_1, \dots, P_{n+2}$ be points of $\mathbb{P}(V)$ in general position. Then there are representatives $\mathbf{v}_i$ with $P_i = [\mathbf{v}_i]$ such that

$$(\mathbf{v}_1, \dots, \mathbf{v}_{n+1}) \text{ is a basis of } V \qquad \text{and} \qquad \mathbf{v}_{n+2} = \mathbf{v}_1 + \cdots + \mathbf{v}_{n+1}.$$

Moreover such a list is unique up to one common scalar: if $(\mathbf{v}'_1, \dots, \mathbf{v}'_{n+2})$ is another, then $\mathbf{v}'_i = a\mathbf{v}_i$ for all i, with a single $a \in F^\times$.

Idea. Start from arbitrary representatives $\mathbf{u}_i$. The first $n+1$ form a basis, so $\mathbf{u}_{n+2}$ has coordinates $c_1, \dots, c_{n+1}$ in it. General position is exactly the statement that **no coordinate is zero**: a vanishing c_j would put $\mathbf{u}_{n+2}$ in the span of the other n basis vectors, making $n+1$ of our points dependent. Non-zero coordinates can be absorbed into the basis vectors, and then the last vector is the sum of the others. For uniqueness, write the second list as $a_i\mathbf{v}_i$ and read off from the relation $\sum \mathbf{v}_i = \mathbf{v}_{n+2}$ that all a_i coincide.

Proof. Choose any representatives $\mathbf{u}_i$ with $P_i = [\mathbf{u}_i]$. By Definition 21.7.2 the list $(\mathbf{u}_1, \dots, \mathbf{u}_{n+1})$ is independent, and it has $n+1 = \dim V$ entries, so it is a basis of V (Theorem 1.6.4). Write

$$\mathbf{u}_{n+2} = c_1\mathbf{u}_1 + \cdots + c_{n+1}\mathbf{u}_{n+1}, \qquad c_i \in F.$$

Every c_j is non-zero. Suppose $c_j = 0$ for some $j \leq n+1$. Then

$$1 \cdot \mathbf{u}_{n+2} - \sum_{i \neq j,\ i \leq n+1} c_i \mathbf{u}_i = \mathbf{0}$$

is a linear relation whose coefficient on $\mathbf{u}_{n+2}$ is $1 \neq 0$, so the list consisting of $\mathbf{u}_{n+2}$ together with the n vectors $\mathbf{u}_i$ ($i \neq j$, $i \leq n+1$) is dependent (Definition 1.4.1). It has $n+1$ entries and its index set has $n+1$ elements, contradicting Definition 21.7.2.

Now set $\mathbf{v}_i := c_i\mathbf{u}_i$ for $i \leq n+1$ and $\mathbf{v}_{n+2} := \mathbf{u}_{n+2}$. Each $c_i \neq 0$, so $[\mathbf{v}_i] = [\mathbf{u}_i] = P_i$, and $(\mathbf{v}_1, \dots, \mathbf{v}_{n+1})$ is still a basis, being the old basis with each vector scaled by a non-zero scalar. By construction $\mathbf{v}_{n+2} = \sum_{i=1}^{n+1} c_i\mathbf{u}_i = \sum_{i=1}^{n+1} \mathbf{v}_i$.

Uniqueness. Let $(\mathbf{v}'_1, \dots, \mathbf{v}'_{n+2})$ be another such list. Since $[\mathbf{v}'_i] = P_i = [\mathbf{v}_i]$, there are $a_i \in F^\times$ with $\mathbf{v}'_i = a_i\mathbf{v}_i$. Applying the defining relation to both lists,

$$a_{n+2} \sum_{i=1}^{n+1} \mathbf{v}_i = a_{n+2}\mathbf{v}_{n+2} = \mathbf{v}'_{n+2} = \sum_{i=1}^{n+1} \mathbf{v}'_i = \sum_{i=1}^{n+1} a_i\mathbf{v}_i.$$

The list $(\mathbf{v}_1, \dots, \mathbf{v}_{n+1})$ is independent, so comparing coefficients gives $a_i = a_{n+2}$ for every $i \leq n+1$. Hence all a_i equal one scalar a.

■

The theorem is now three lines of linear algebra.

Theorem 21.7.5 — Fundamental Theorem of Projective Geometry

Let $\dim V = \dim W = n+1 \geq 1$. Let $P_1, \dots, P_{n+2}$ be points of $\mathbb{P}(V)$ in general position and $Q_1, \dots, Q_{n+2}$ points of $\mathbb{P}(W)$ in general position. Then there is **exactly one** projectivity $f\colon \mathbb{P}(V) \to \mathbb{P}(W)$ with

$$f(P_i) = Q_i \qquad \text{for } i = 1, \dots, n+2.$$

Idea. Normalize both lists by Lemma 21.7.4. The first $n+1$ normalized vectors on each side are bases, so there is a unique linear map sending one basis to the other, and the normalization was arranged so that this map automatically takes the $(n+2)$-nd vector to the $(n+2)$-nd. For uniqueness, a second projectivity differs from the first by an operator that scales each of $\mathbf{v}_1, \dots, \mathbf{v}_{n+1}$ and also their sum; the same coefficient comparison as in the lemma forces all the scalars to agree.

Proof. By Lemma 21.7.4 choose representatives $\mathbf{v}_1, \dots, \mathbf{v}_{n+2}$ of the P_i with $(\mathbf{v}_1, \dots, \mathbf{v}_{n+1})$ a basis of V and $\mathbf{v}_{n+2} = \mathbf{v}_1 + \cdots + \mathbf{v}_{n+1}$, and likewise $\mathbf{w}_1, \dots, \mathbf{w}_{n+2}$ for the Q_i.

Existence. By Theorem 3.1.5 there is a unique linear $T\colon V \to W$ with $T\mathbf{v}_i = \mathbf{w}_i$ for $i \leq n+1$. Its image is $\operatorname{span}(\mathbf{w}_1, \dots, \mathbf{w}_{n+1}) = W$ by Theorem 3.2.4, so T is surjective, and since $\dim V = \dim W$ is finite, T is an isomorphism by Corollary 3.3.2 (e). By linearity,

$$T\mathbf{v}_{n+2} = T\Big(\sum_{i=1}^{n+1} \mathbf{v}_i\Big) = \sum_{i=1}^{n+1} \mathbf{w}_i = \mathbf{w}_{n+2}.$$

Hence $[T](P_i) = [T\mathbf{v}_i] = [\mathbf{w}_i] = Q_i$ for all $i \leq n+2$.

Uniqueness. Let $[S]$ be a projectivity with $[S](P_i) = Q_i$ for all i, where $S\colon V \to W$ is an isomorphism. Then $[S\mathbf{v}_i] = [\mathbf{w}_i]$, so there are $\mu_i \in F^\times$ with $S\mathbf{v}_i = \mu_i \mathbf{w}_i$. Put $R = T^{-1}S \in \mathrm{GL}(V)$; then $R\mathbf{v}_i = \mu_i \mathbf{v}_i$ for every $i \leq n+2$. Applying R to $\mathbf{v}_{n+2} = \sum_{i \leq n+1} \mathbf{v}_i$,

$$\mu_{n+2} \sum_{i=1}^{n+1} \mathbf{v}_i = R\mathbf{v}_{n+2} = \sum_{i=1}^{n+1} R\mathbf{v}_i = \sum_{i=1}^{n+1} \mu_i \mathbf{v}_i.$$

By independence of $(\mathbf{v}_1, \dots, \mathbf{v}_{n+1})$, $\mu_i = \mu_{n+2} =: \mu$ for all $i \leq n+1$. So R agrees with $\mu \operatorname{id}_V$ on a basis, hence $R = \mu \operatorname{id}_V$ (Theorem 3.1.5), and $S = TR = \mu T$. By Theorem 21.7.3 (a), $[S] = [T]$. This proves the theorem. ∎

Existence and uniqueness are both used constantly: existence says we may always **choose coordinates** so that $n+2$ prescribed points in general position become $[\mathbf{e}_0], \dots, [\mathbf{e}_n]$ and $[1 : \cdots : 1]$; uniqueness says that having done so, nothing is left to choose.

Example. (Moving the standard frame)

Work in $\mathbb{P}^2(\mathbb{Q})$. Find the projectivity carrying

$$[1:0:0], \quad [0:1:0], \quad [0:0:1], \quad [1:1:1]$$

to

$$Q_0 = [1:1:0], \quad Q_1 = [0:1:1], \quad Q_2 = [1:0:1], \quad Q_3 = [4:3:5],$$

after checking that the second list is in general position.

Solution. General position. Form the 3×3 determinant of each triple of representatives, taken as columns. For the triples (Q_0, Q_1, Q_2), (Q_0, Q_1, Q_3), (Q_0, Q_2, Q_3), (Q_1, Q_2, Q_3) these determinants are 2, 6, -4, 2. All are non-zero in $\mathbb{Q}$, so every triple is independent (Theorem 6.5.2 together with the fact that the columns of an invertible matrix are independent), and the four points are in general position.

Normalizing. Following Lemma 21.7.4, we need scalars $\lambda_0, \lambda_1, \lambda_2$ with

$$\lambda_0(1,1,0) + \lambda_1(0,1,1) + \lambda_2(1,0,1) = (4,3,5),$$

that is, $\lambda_0 + \lambda_2 = 4$, $\lambda_0 + \lambda_1 = 3$, $\lambda_1 + \lambda_2 = 5$. Adding all three gives $\lambda_0 + \lambda_1 + \lambda_2 = 6$, so $\lambda_0 = 6 - 5 = 1$, $\lambda_1 = 6 - 4 = 2$, $\lambda_2 = 6 - 3 = 3$. All are non-zero, as the lemma promised.

The matrix. The standard frame is already normalized, with $\mathbf{e}_0 + \mathbf{e}_1 + \mathbf{e}_2 = (1,1,1)$. So the map sends $\mathbf{e}_i$ to $\lambda_i \mathbf{q}_i$, that is,

$$\mathbf{A} = \begin{pmatrix} 1 & 0 & 3 \\ 1 & 2 & 0 \\ 0 & 2 & 3 \end{pmatrix}, \qquad \det \mathbf{A} = 12 \neq 0.$$

Check. The columns are $(1,1,0)$, $(0,2,2)$, $(3,0,3)$, which represent Q_0, Q_1, Q_2; and $\mathbf{A}(1,1,1) = (4,3,5)$, which represents Q_3. By Theorem 21.7.5 this $[\mathbf{A}]$ is the only projectivity doing this, so every other matrix that works is a scalar multiple of $\mathbf{A}$.

Now the negative result promised above. It is not that the proof of Theorem 21.7.5 is wasteful; as long as F has more than two elements, $n+1$ points genuinely do not suffice.

Proposition 21.7.6 — What Fixes the Coordinate Points

Let $n \geq 1$. A projectivity of $\mathbb{P}^n(F)$ fixes each of the $n+1$ points $[\mathbf{e}_0], \ldots, [\mathbf{e}_n]$ if and only if it is $[\mathbf{D}]$ for an invertible **diagonal** matrix $\mathbf{D}$. The group of such projectivities is trivial if and only if $F = \mathbb{F}_2$.

Proof. ($\Leftarrow$) If $\mathbf{D} = \operatorname{diag}(d_0, \ldots, d_n)$ with all $d_i \neq 0$, then $\mathbf{D}\mathbf{e}_i = d_i \mathbf{e}_i$, so $[\mathbf{D}][\mathbf{e}_i] = [\mathbf{e}_i]$.

($\Rightarrow$) Let $[\mathbf{A}]$ fix each $[\mathbf{e}_i]$. Then $\mathbf{A}\mathbf{e}_i = d_i \mathbf{e}_i$ for some $d_i \in F^\times$. But $\mathbf{A}\mathbf{e}_i$ is the i-th column of $\mathbf{A}$ (Theorem 0.9.2), so every column of $\mathbf{A}$ has a single non-zero entry, on the diagonal: $\mathbf{A} = \operatorname{diag}(d_0, \ldots, d_n)$.

For the last sentence, by Theorem 21.7.3 (a) we have $[\mathbf{D}] = [\mathbf{I}_{n+1}]$ if and only if $\mathbf{D} = \lambda \mathbf{I}_{n+1}$, that is, if and only if $d_0 = \cdots = d_n$. So the group is trivial exactly when every tuple $(d_0, \ldots, d_n) \in (F^\times)^{n+1}$ is constant, which, since $n \geq 1$, happens exactly when $F^\times$ has one element, that is, when $F = \mathbb{F}_2$.

■

Remark. $n+1$ **points do not determine a projectivity.** Let F have an element $c \neq 0, 1$ — every field except $\mathbb{F}_2$. In $\mathbb{P}^1(F)$ the two points $[1:0]$ and $[0:1]$ are in general position, and both $[\mathbf{I}_2]$ and $[\mathrm{diag}(1,c)]$ fix them, yet they are different maps: the second sends $[1:1]$ to $[1:c] \neq [1:1]$. The same works in $\mathbb{P}^n(F)$ with $\mathbf{D} = \mathrm{diag}(1,\dots,1,c)$ and the point $[1:\cdots:1]$. So the count of $n+2$ in Theorem 21.7.5 is exact.

Over $\mathbb{F}_2$ this counterexample is unavailable, and Proposition 21.7.6 already shows why: the group it describes is trivial there. So the negative result needs the hypothesis that F has at least three elements, and over the one excluded field the situation is genuinely different.

Proposition 21.7.7 — Over the Two-Element Field, $n+1$ Points Suffice

Let $n \geq 1$ and $F = \mathbb{F}_2$. Given two lists $P_0, \dots, P_n$ and $Q_0, \dots, Q_n$ of $n+1$ points of $\mathbb{P}^n(\mathbb{F}_2)$, each in general position, there is exactly one projectivity of $\mathbb{P}^n(\mathbb{F}_2)$ carrying P_i to Q_i for every i.

Proof. Over $\mathbb{F}_2$ the only non-zero scalar is 1, so each point has exactly one representative: write $P_i = [\mathbf{v}_i]$ and $Q_i = [\mathbf{w}_i]$. By Definition 21.7.2 the lists $(\mathbf{v}_0, \dots, \mathbf{v}_n)$ and $(\mathbf{w}_0, \dots, \mathbf{w}_n)$ are independent, and each has $n+1 = \dim \mathbb{F}_2^{n+1}$ entries, hence each is a basis (Theorem 1.6.4). By Theorem 3.1.5 there is a unique linear T with $T\mathbf{v}_i = \mathbf{w}_i$ for all i; its image is $\mathrm{span}(\mathbf{w}_0, \dots, \mathbf{w}_n) = \mathbb{F}_2^{n+1}$ (Theorem 3.2.4), so it is surjective and hence an isomorphism (Corollary 3.3.2 (e)). Thus $[T]$ carries P_i to Q_i.

If $[S]$ does too, then $[S\mathbf{v}_i] = [\mathbf{w}_i]$, so $S\mathbf{v}_i = \mu_i \mathbf{w}_i$ with $\mu_i \in \mathbb{F}_2 \setminus \{0\} = \{1\}$, that is, $S\mathbf{v}_i = \mathbf{w}_i = T\mathbf{v}_i$ for every i. Two linear maps agreeing on a basis are equal (Theorem 3.1.5), so $S = T$ and $[S] = [T]$.

■

So the theorem to remember is Theorem 21.7.5, with the count $n+2$ that works over every field; $\mathbb{F}_2$ is the one field where a smaller count also works, for the accidental reason that it has no scalars to spare.

Quick check. Exhibit two different projectivities of $\mathbb{P}^2(\mathbb{Q})$ that agree on $[1:0:0]$, $[0:1:0]$ and $[0:0:1]$, and name a point where they disagree.

Solution. Take $[\mathbf{I}_3]$ and $[\mathbf{D}]$ with $\mathbf{D} = \mathrm{diag}(1,1,2)$. Both fix the three coordinate points. They differ at $[1:1:1]$, which $[\mathbf{D}]$ sends to $[1:1:2]$; and $[1:1:2] \neq [1:1:1]$, since $(1,1,2)$ is not a scalar multiple of $(1,1,1)$. By Theorem 21.7.3 (a) the two projectivities are different, because $\mathbf{D}$ is not a scalar multiple of $\mathbf{I}_3$.

21.7.4 The cross-ratio

Three distinct points on a projective line can be moved to any other three, by Theorem 21.7.5 with $n = 1$. A fourth point cannot: the theorem has used up all its freedom. What is left over is one invariant, and it is a point of $\mathbb{P}^1(F)$.

Definition 21.7.3 — Cross-Ratio

Let L be a projective line, that is, a projective space of dimension 1 over F, let $A, B, C \in L$ be **pairwise distinct**, and let $D \in L$ be arbitrary. Let $f\colon L \to \mathbb{P}^1(F)$ be the unique projectivity with

$$f(A) = [1:0], \qquad f(B) = [0:1], \qquad f(C) = [1:1].$$

The **cross-ratio** of the ordered quadruple is the point

$$(A, B; C, D) \coloneqq f(D) \in \mathbb{P}^1(F).$$

The projectivity f exists and is unique because three pairwise distinct points of a line are in general position (Definition 21.7.2 with $n = 1$), on both sides. The cross-ratio is a **point of** $\mathbb{P}^1(F)$, not a scalar; in the chart $[\lambda : \mu] \mapsto \lambda/\mu$ it becomes a scalar whenever $\mu \neq 0$, and the one excluded value, $[1:0]$, occurs exactly when $D = A$, since f is injective. Likewise $(A, B; C, D) = [0:1]$ exactly when $D = B$, and $[1:1]$ exactly when $D = C$.

A formula makes this computable.

Proposition 21.7.8 — Computing the Cross-Ratio

In the situation of Definition 21.7.3, write $L = \mathbb{P}(U)$ with $\dim U = 2$, choose representatives $A = [\mathbf{a}]$, $B = [\mathbf{b}]$, and expand

$$\mathbf{c} = c_1\mathbf{a} + c_2\mathbf{b}, \qquad \mathbf{d} = d_1\mathbf{a} + d_2\mathbf{b}$$

for representatives $\mathbf{c}$ of C and $\mathbf{d}$ of D. Then $c_1 \neq 0$, $c_2 \neq 0$, and

$$(A, B; C, D) = [\, d_1c_2 : d_2c_1 \,].$$

If moreover $L = \mathbb{P}^1(F)$ and the four points lie in the chart $\mu \neq 0$, with scalars a, b, c, d given by $[t:1] \mapsto t$, then

$$(A, B; C, D) = \Big[\, (c-a)(d-b) \;:\; (c-b)(d-a) \,\Big].$$

Idea. Since $A \neq B$, the pair $(\mathbf{a}, \mathbf{b})$ is a basis of U, so the expansions exist. The projectivity of Definition 21.7.3 is the one induced by the linear map sending $c_1\mathbf{a} \mapsto \mathbf{e}_0$ and $c_2\mathbf{b} \mapsto \mathbf{e}_1$, because that map sends $\mathbf{c}$ to $\mathbf{e}_0 + \mathbf{e}_1$ — this is Lemma 21.7.4 for $n = 1$, done by hand. Then evaluate it at $\mathbf{d}$. For the chart formula, take $\mathbf{a} = (a, 1)$, $\mathbf{b} = (b, 1)$ and solve two 2×2 systems.

Proof. The points $A \neq B$ give independent representatives (Definition 21.7.2), and $\dim U = 2$, so $(\mathbf{a}, \mathbf{b})$ is a basis of U (Theorem 1.6.4) and the expansions exist and are unique. If $c_1 = 0$ then $\mathbf{c} = c_2\mathbf{b}$, so $C = B$; if $c_2 = 0$ then $C = A$. Both are excluded, so $c_1c_2 \neq 0$.

Let $T\colon U \to F^2$ be the linear map with $T(c_1\mathbf{a}) = \mathbf{e}_0$ and $T(c_2\mathbf{b}) = \mathbf{e}_1$ (Theorem 3.1.5; $(c_1\mathbf{a}, c_2\mathbf{b})$ is a basis since $c_1c_2 \neq 0$). Its image is $\operatorname{span}(\mathbf{e}_0, \mathbf{e}_1) = F^2$ (Theorem 3.2.4), so

it is surjective, hence an isomorphism by Corollary 3.3.2 (e). Then

$$[T](A) = [T\mathbf{a}] = [c_1^{-1}\mathbf{e}_0] = [1:0], \qquad [T](B) = [0:1],$$

and $[T](C) = [T(c_1\mathbf{a} + c_2\mathbf{b})] = [\mathbf{e}_0 + \mathbf{e}_1] = [1:1]$. By the uniqueness in Theorem 21.7.5, $[T]$ is the map f of Definition 21.7.3. Finally

$$f(D) = [T(d_1\mathbf{a} + d_2\mathbf{b})] = \left[\, d_1c_1^{-1}\mathbf{e}_0 + d_2c_2^{-1}\mathbf{e}_1 \,\right] = \left[\, d_1c_1^{-1} : d_2c_2^{-1} \,\right],$$

and multiplying both entries by $c_1c_2 \neq 0$ gives $[\, d_1c_2 : d_2c_1 \,]$.

For the chart formula take $\mathbf{a} = (a, 1)$, $\mathbf{b} = (b, 1)$, $\mathbf{c} = (c, 1)$, $\mathbf{d} = (d, 1)$; these are representatives of the four points, and $a \neq b$ because $A \neq B$. Solving $c_1a + c_2b = c$, $c_1 + c_2 = 1$ gives

$$c_1 = \frac{c-b}{a-b}, \qquad c_2 = \frac{a-c}{a-b},$$

and the same computation with d in place of c gives d_1, d_2. Hence

$$d_1c_2 = \frac{(d-b)(a-c)}{(a-b)^2}, \quad d_2c_1 = \frac{(a-d)(c-b)}{(a-b)^2},$$

and clearing the common factor $(a-b)^{-2}$ and the common sign gives $(A, B; C, D) = [\,(c-a)(d-b) : (c-b)(d-a)\,]$, as claimed.

■

Quick check. Proposition 21.7.8 insists that A, B and C be pairwise distinct, but puts no condition at all on D. Where in the proof is each of these used, and why is $[\, d_1c_2 : d_2c_1 \,]$ a point of $\mathbb{P}^1(F)$ for every D?

Solution. $A \neq B$ makes $(\mathbf{a}, \mathbf{b})$ independent, hence a basis, which is what lets $\mathbf{c}$ and $\mathbf{d}$ be expanded at all. $C \neq A$ and $C \neq B$ are what force $c_2 \neq 0$ and $c_1 \neq 0$, which is what makes $(c_1\mathbf{a}, c_2\mathbf{b})$ a basis and lets us divide by c_1 and c_2. For D nothing is needed: $\mathbf{d} \neq \mathbf{0}$, so $(d_1, d_2) \neq (0, 0)$, and since $c_1c_2 \neq 0$ the pair (d_1c_2, d_2c_1) is again not $(0, 0)$. So it names a point of $\mathbb{P}^1(F)$, whichever point D is.

Theorem 21.7.9 — Invariance and Completeness of the Cross-Ratio

Let L and L' be projective lines over F.

(a) **(Invariance)** If $g\colon L \to L'$ is a projectivity and $A, B, C \in L$ are pairwise distinct, then for every $D \in L$, $\big(g(A), g(B); g(C), g(D)\big) = (A, B; C, D)$.

(b) **(Completeness)** Let $A, B, C \in L$ be pairwise distinct and $A', B', C' \in L'$ pairwise distinct, and let $D \in L$, $D' \in L'$. Then there is a projectivity $L \to L'$ carrying A, B, C, D to A', B', C', D' if and only if $(A, B; C, D) = (A', B'; C', D')$.

Idea. Both halves come from the uniqueness in Theorem 21.7.5, with no computation. For (a), $f \circ g^{-1}$ normalizes the image triple, so it **is** the normalizing map of that triple; evaluate it at $g(D)$. For (b), let h be the unique projectivity matching the triples; by (a) it preserves the cross-ratio, and the cross-ratio determines the fourth point because

the normalizing map is injective.

Proof.

(a) Let $f\colon L \to \mathbb{P}^1(F)$ be the projectivity of Definition 21.7.3 for (A, B, C). Since g is a bijection (Proposition 21.7.1), $g(A), g(B), g(C)$ are pairwise distinct, so the corresponding map $f'\colon L' \to \mathbb{P}^1(F)$ exists. The composition $f \circ g^{-1}\colon L' \to \mathbb{P}^1(F)$ is a projectivity (Proposition 21.7.1) and sends $g(A) \mapsto [1:0]$, $g(B) \mapsto [0:1]$, $g(C) \mapsto [1:1]$. By the uniqueness in Theorem 21.7.5, $f' = f \circ g^{-1}$. Hence

$$\big(g(A), g(B); g(C), g(D)\big) = f'\big(g(D)\big) = f(D) = (A, B; C, D).$$

(b) ($\Rightarrow$) is (a). ($\Leftarrow$) Let $h\colon L \to L'$ be the unique projectivity with $h(A) = A'$, $h(B) = B'$, $h(C) = C'$ (Theorem 21.7.5, $n = 1$). Let f' be the normalizing map for (A', B', C'). By (a),

$$f'\big(h(D)\big) = (A', B'; C', h(D)) = (A, B; C, D) = (A', B'; C', D') = f'(D').$$

Since f' is injective, $h(D) = D'$. This proves the theorem.

■

So four points on a line carry exactly one piece of data that survives every projectivity, and two quadruples are projectively equivalent precisely when that datum agrees.

Example. (A cross-ratio, before and after)

On $\mathbb{P}^1(\mathbb{Q})$, use the chart $[t:1] \mapsto t$ and take the points with parameters $a = 0$, $b = 1$, $c = 3$, $d = 7$. Compute $(A, B; C, D)$. Then apply the projectivity $[\mathbf{A}]$ with $\mathbf{A} = \begin{pmatrix} 1 & 2 \\ 1 & 3 \end{pmatrix}$ and compute the cross-ratio of the images.

Solution. By Proposition 21.7.8,

$$(A, B; C, D) = \big[\,(3-0)(7-1) : (3-1)(7-0)\,\big] = [18:14] = [9:7],$$

which is the scalar $9/7$ in the chart.

The matrix $\mathbf{A}$ has $\det \mathbf{A} = 3 - 2 = 1 \neq 0$, so $[\mathbf{A}]$ is a projectivity. It sends $[t:1]$ to $[t+2 : t+3]$, which lies in the chart when $t \neq -3$ and is then the scalar $(t+2)/(t+3)$. The four parameters become

$$0 \mapsto \tfrac{2}{3}, \qquad 1 \mapsto \tfrac{3}{4}, \qquad 3 \mapsto \tfrac{5}{6}, \qquad 7 \mapsto \tfrac{9}{10}.$$

The images are not equally spaced in any sense, and the gaps have changed from $1, 2, 4$ to $\tfrac{1}{12}, \tfrac{1}{12}, \tfrac{1}{15}$. The cross-ratio, however, is

$$\Big[\big(\tfrac{5}{6} - \tfrac{2}{3}\big)\big(\tfrac{9}{10} - \tfrac{3}{4}\big) : \big(\tfrac{5}{6} - \tfrac{3}{4}\big)\big(\tfrac{9}{10} - \tfrac{2}{3}\big)\Big] = \Big[\tfrac{1}{40} : \tfrac{7}{360}\Big] = [9:7],$$

after multiplying both entries by 360. This is Theorem 21.7.9 (a) in one instance.

As a second check, run Proposition 21.7.8 in its first form with $\mathbf{a} = (0, 1)$ and $\mathbf{b} = (1, 1)$: solving gives $(c_1, c_2) = (-2, 3)$ and $(d_1, d_2) = (-6, 7)$, so $[\, d_1c_2 : d_2c_1 \,] = [-18 : -14] = [9 : 7]$.

Warning. **The cross-ratio depends on the order of the four points.** It is a function of an **ordered** quadruple. Swapping the first two points inverts it: with the notation of Proposition 21.7.8, $(B, A; C, D) = [\, d_2c_1 : d_1c_2 \,]$, the two entries exchanged. With $a, b, c, d = 0, 1, 3, 7$ as above, $(A, B; C, D) = [9 : 7]$ while $(B, A; C, D) = [7 : 9]$, and $9/7 \neq 7/9$. Writing "the cross-ratio of four points" without fixing an order names six different values in general.

21.7.5 Perspectivities

The classical source of projectivities is projection from a point, and it is worth seeing that the synthetic construction is the linear-algebraic one.

Proposition 21.7.10 — Projection From a Point Is a Projectivity

Let $\dim V = 3$, let $L = \mathbb{P}(U)$ and $L' = \mathbb{P}(U')$ be lines in the projective plane $\mathbb{P}(V)$, and let $O = [\mathbf{o}]$ be a point lying on neither. For $P \in L$, let $\pi(P)$ be the unique point in which the line $O \vee P$ meets L'. Then $\pi \colon L \to L'$ is well defined, and it is the projectivity induced by the restriction to U of the projection of V onto U' along $\operatorname{span}(\mathbf{o})$. In particular π preserves cross-ratio.

Idea. Everything is forced by dimensions in a 3-dimensional V. Since $\mathbf{o} \notin U'$ and $\dim U' = 2$, we have $V = U' \oplus \operatorname{span}(\mathbf{o})$, so every vector splits uniquely as "a piece in U' plus a multiple of $\mathbf{o}$". Throwing away the multiple of $\mathbf{o}$ is a linear map, and on U it is injective because $\mathbf{o} \notin U$. That map is the projection, and the line $O \vee P$ is exactly where the discarded multiple of $\mathbf{o}$ lives.

Proof. Since $\mathbf{o} \neq \mathbf{0}$ and $\mathbf{o} \notin U'$, the sum $U' + \operatorname{span}(\mathbf{o})$ properly contains U', so its dimension exceeds 2 and it equals V. Since $\dim U' + \dim \operatorname{span}(\mathbf{o}) = 2 + 1 = 3 = \dim(U' + \operatorname{span}(\mathbf{o}))$, the sum is direct by Theorem 1.7.4, so $V = U' \oplus \operatorname{span}(\mathbf{o})$. Let $\rho \colon V \to V$ be the projection onto U' along $\operatorname{span}(\mathbf{o})$ (Theorem 3.10.1 (b)), so that

$$\mathbf{x} = \rho(\mathbf{x}) + t(\mathbf{x})\,\mathbf{o}, \qquad \rho(\mathbf{x}) \in U',\ t(\mathbf{x}) \in F,$$

is the unique such splitting, and ρ is linear.

The restriction $T := \rho|_U \colon U \to U'$ is an isomorphism. If $\mathbf{u} \in U$ and $\rho(\mathbf{u}) = \mathbf{0}$, then $\mathbf{u} = t(\mathbf{u})\mathbf{o}$; since $\mathbf{o} \notin U$, this forces $t(\mathbf{u}) = 0$ and $\mathbf{u} = \mathbf{0}$. So T is injective, and $\dim U = \dim U' = 2$ makes it an isomorphism (Corollary 3.3.2 (e)).

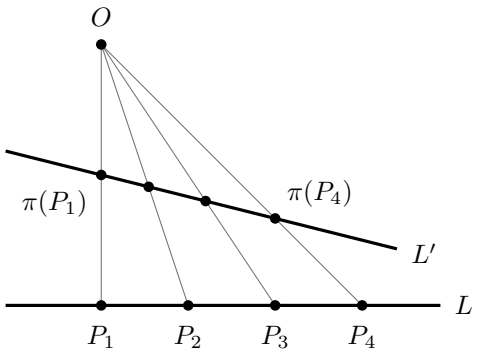
$[T] = \pi$. Let $P = [\mathbf{u}]$ with $\mathbf{0} \neq \mathbf{u} \in U$. Since $\mathbf{o} \notin U$, the vector $\mathbf{o}$ is not a multiple of $\mathbf{u}$, so $\operatorname{span}(\mathbf{u}, \mathbf{o})$ has dimension 2. The projective subspace $\mathbb{P}(\operatorname{span}(\mathbf{u}, \mathbf{o}))$ contains O and P, and any projective subspace $\mathbb{P}(W)$ containing both has $\mathbf{u}, \mathbf{o} \in W$, hence $\operatorname{span}(\mathbf{u}, \mathbf{o}) \subseteq W$; so $O \vee P = \mathbb{P}(\operatorname{span}(\mathbf{u}, \mathbf{o}))$, a line. Now $T\mathbf{u} = \mathbf{u} - t(\mathbf{u})\mathbf{o} \in \operatorname{span}(\mathbf{u}, \mathbf{o}) \cap U'$, and $T\mathbf{u} \neq \mathbf{0}$, so $[T\mathbf{u}]$ lies on both $O \vee P$ and L'. These two lines are distinct, because O lies on the

first and not on the second, so

$$\dim\bigl(\operatorname{span}(\mathbf{u},\mathbf{o})\cap U'\bigr) = 2+2-\dim\bigl(\operatorname{span}(\mathbf{u},\mathbf{o})+U'\bigr) = 4-3 = 1$$

by Theorem 1.7.3, the sum being all of V since it properly contains U'. Hence the intersection point is unique and equals $[T\mathbf{u}]$. So π is well defined and $\pi = [T]$, a projectivity. Cross-ratio invariance is Theorem 21.7.9 (a).

■



projection from O carries L to L':
the four points are equally spaced on L and not on L',
but both quadruples have cross-ratio $[4:3]$

The two lines need not be distinct. If $L = L'$, then for $P \in L$ the line $O \vee P$ is not L, because O lies on the first and not on the second, so the two meet in exactly one point (Corollary 21.6.7) and that point is P: the construction gives $\pi = \mathrm{id}_L$. The classical statement takes the lines distinct, but the proof above never uses it.

Informally, this is what a photograph does. As a physical model rather than a theorem: a camera records, for each point of the scene, the point where the line from that point to the lens meets the film, and along any one line of the scene that is exactly the map π. So a photograph of a straight railway track distorts the spacing of the sleepers but not their cross-ratio. Four equally spaced sleepers, with parameters $0, 1, 2, 3$ along the track, have cross-ratio

$$\bigl[\,(2-0)(3-1) : (2-1)(3-0)\,\bigr] = [4:3],$$

and the four images on the film, bunched ever closer together toward the horizon, have cross-ratio $[4:3]$ as well. Equal spacing is not a projective notion; $[4:3]$ is.

21.7.6 Affine maps inside the projective group

The chapter began with affine geometry, and we can now say exactly how it sits inside projective geometry. By Theorem 21.6.2, $\mathbb{P}^n(F)$ is the disjoint union of the chart $\{x_0 \neq 0\}$, identified with affine n-space by

$$[x_0 : x_1 : \cdots : x_n] \longmapsto \Bigl(\frac{x_1}{x_0}, \ldots, \frac{x_n}{x_0}\Bigr),$$

and the hyperplane at infinity $H_\infty = \{[\mathbf{x}] : x_0 = 0\} = \mathbb{P}(\operatorname{span}(\mathbf{e}_1, \ldots, \mathbf{e}_n))$.

Theorem 21.7.11 — Affine Maps Are the Projectivities Fixing Infinity

Let $n \geq 1$ and let g be a projectivity of $\mathbb{P}^n(F)$. Then $g(H_\infty) = H_\infty$ if and only if $g = [\mathbf{A}]$ for a matrix of the block form

$$\mathbf{A} = \begin{pmatrix} 1 & \mathbf{0}^\top \\ \mathbf{b} & \mathbf{M} \end{pmatrix}, \qquad \mathbf{b} \in F^n, \quad \mathbf{M} \in \mathrm{GL}_n(F).$$

In that case g maps the chart $\{x_0 \neq 0\}$ onto itself, and in the affine coordinates above it acts as

$$\mathbf{x} \longmapsto \mathbf{M}\mathbf{x} + \mathbf{b},$$

an invertible affine map with linear part $\mathbf{x} \mapsto \mathbf{M}\mathbf{x}$ (Definition 21.1.3, Theorem 21.1.5). Conversely every invertible affine map of F^n arises from exactly one such $\mathbf{A}$.

Idea. "g fixes H_∞ as a set" says that the matrix maps $\mathrm{span}(\mathbf{e}_1, \ldots, \mathbf{e}_n)$ into itself, which is a statement about the top entry of n columns. Invertibility then forces the remaining corner entry to be non-zero, and since a projectivity only knows its matrix up to a scalar, we may divide by that entry. What is left is the block matrix that Section 01 already introduced for affine maps — the same matrix, with the extra coordinate moved from last place to first.

Proof. Write $H = \mathrm{span}(\mathbf{e}_1, \ldots, \mathbf{e}_n) = \{\mathbf{x} \in F^{n+1} : x_0 = 0\}$, so $H_\infty = \mathbb{P}(H)$, and let $g = [\mathbf{A}]$ with $\mathbf{A} \in \mathrm{GL}_{n+1}(F)$.

($\Rightarrow$) Suppose $g(H_\infty) = H_\infty$. By Proposition 21.7.2, $\mathbb{P}(\mathbf{A}H) = \mathbb{P}(H)$, and hence $\mathbf{A}H = H$: a non-zero $\mathbf{h} \in \mathbf{A}H$ has $[\mathbf{h}] \in \mathbb{P}(H)$, so $\mathbf{h} \in H$, and conversely. Thus $\mathbf{A}\mathbf{e}_j \in H$ for $j = 1, \ldots, n$, which says the columns $1, \ldots, n$ of $\mathbf{A}$ have zero entry in row 0. Writing column 0 as $(a, \mathbf{b})$ with $a \in F$ and $\mathbf{b} \in F^n$, and the lower right $n \times n$ block as $\mathbf{M}$,

$$\mathbf{A} = \begin{pmatrix} a & \mathbf{0}^\top \\ \mathbf{b} & \mathbf{M} \end{pmatrix}.$$

Here $\mathbf{M}$ is invertible: $\mathbf{A}$ restricts to an injective map $H \to H$, which is therefore surjective (Corollary 3.3.2 (e)), and that restriction is $\mathbf{M}$ in the basis $(\mathbf{e}_1, \ldots, \mathbf{e}_n)$ of H. And $a \neq 0$: if $a = 0$ then column 0 of $\mathbf{A}$ lies in $H = \mathbf{A}H$, so $\mathbf{A}\mathbf{e}_0 = \mathbf{A}\mathbf{h}$ for some $\mathbf{h} \in H$, and injectivity would give $\mathbf{e}_0 \in H$, which is false. Replacing $\mathbf{A}$ by $a^{-1}\mathbf{A}$, which by Theorem 21.7.3 (a) induces the same projectivity, puts $\mathbf{A}$ in the stated form with 1 in the corner.

($\Leftarrow$) For $\mathbf{A}$ of the stated form and $\mathbf{x} \in H$, the first entry of $\mathbf{A}\mathbf{x}$ is $1 \cdot 0 + \mathbf{0}^\top \mathbf{x}' = 0$ where $\mathbf{x}'$ collects the last n entries, so $\mathbf{A}H \subseteq H$; and $\mathbf{A}$ is invertible, since $\mathbf{A}\mathbf{x} = \mathbf{0}$ forces $x_0 = 0$ and then $\mathbf{M}\mathbf{x}' = \mathbf{0}$, so $\mathbf{x}' = \mathbf{0}$. By Corollary 3.3.2 (e) again $\mathbf{A}H = H$, and Proposition 21.7.2 gives $g(H_\infty) = H_\infty$.

The action on the chart. Since g is a bijection of $\mathbb{P}^n(F)$ mapping H_∞ onto H_∞, it maps the complement $\{x_0 \neq 0\}$ onto itself. A point of the chart is $[1 : \mathbf{x}]$ with $\mathbf{x} \in F^n$, and

$$\mathbf{A}\begin{pmatrix} 1 \\ \mathbf{x} \end{pmatrix} = \begin{pmatrix} 1 \\ \mathbf{M}\mathbf{x} + \mathbf{b} \end{pmatrix},$$

whose affine coordinates are $\mathbf{Mx} + \mathbf{b}$. By Theorem 21.1.5 this is the affine map with linear part $\mathbf{x} \mapsto \mathbf{Mx}$ and value $\mathbf{b}$ at the origin, and it is invertible because $\mathbf{M}$ is.

Converse. Given an invertible affine map $\mathbf{x} \mapsto \mathbf{Mx} + \mathbf{b}$ of F^n, the matrix displayed above induces a projectivity fixing H_∞ and restricting to it. If two such matrices $\mathbf{A}$, $\mathbf{A}'$ induce the same projectivity, then $\mathbf{A}' = \lambda\mathbf{A}$ by Theorem 21.7.3 (a), and comparing the corner entries gives $\lambda = 1$, so $\mathbf{A}' = \mathbf{A}$. This proves the theorem.

■

So the affine group of F^n is the subgroup of $\mathrm{PGL}_{n+1}(F)$ stabilizing one hyperplane. Projective geometry is affine geometry with the hyperplane at infinity forgotten, and every affine notion that a projectivity can destroy — parallelism, ratios of lengths along a line, midpoints — is a notion that mentions H_∞. The cross-ratio never does, which is why it survives.

21.7.7 Exercises

21.7.7.1 A. Check your understanding

Exercise A1.

(a) State precisely when two isomorphisms $S, T\colon V \to W$ induce the same projectivity.

(b) How many points, and satisfying what condition, determine a projectivity of $\mathbb{P}^n(F)$ uniquely?

(c) True or false, with a reason: a projectivity of $\mathbb{P}^2(\mathbb{Q})$ fixing four points in general position is the identity.

(d) True or false, with a reason: det is a well-defined function on $\mathrm{PGL}_3(\mathbb{Q})$.

(e) What is $(A, B; C, B)$, and why?

Solution.

(a) Exactly when $S = \lambda T$ for some $\lambda \in F^\times$ (Theorem 21.7.3 (a)).

(b) $n + 2$ points in general position, that is, $n + 2$ points of which every $n + 1$ have linearly independent representatives (Definition 21.7.2, Theorem 21.7.5).

(c) True. Here $n = 2$, so four points in general position are $n + 2$ points in general position. The identity is one projectivity fixing them, and by the uniqueness in Theorem 21.7.5 it is the only one.

(d) False. The matrices $\mathbf{I}_3$ and $2\mathbf{I}_3$ induce the same projectivity but have determinants 1 and 8.

(e) $(A, B; C, B) = [0 : 1]$. By Definition 21.7.3 the cross-ratio is $f(D)$ with $D = B$, and $f(B) = [0 : 1]$ by the definition of f.

21.7.7.2 B. Practice

Exercise B1: A projectivity of the line.

Find a matrix inducing the projectivity of $\mathbb{P}^1(\mathbb{Q})$ that sends $[1 : 0]$, $[0 : 1]$, $[1 : 1]$ to

$[1:1]$, $[1:2]$, $[2:3]$ respectively, and verify the three conditions.

Solution. The source triple is already normalized in the sense of Lemma 21.7.4: $(\mathbf{e}_0, \mathbf{e}_1)$ is a basis and $(1,1) = \mathbf{e}_0 + \mathbf{e}_1$. Normalize the target: we need $\lambda_1(1,1) + \lambda_2(1,2) = (2,3)$, that is, $\lambda_1 + \lambda_2 = 2$ and $\lambda_1 + 2\lambda_2 = 3$. Subtracting, $\lambda_2 = 1$, then $\lambda_1 = 1$. Both are non-zero, as Lemma 21.7.4 guarantees.

So the map sends $\mathbf{e}_0 \mapsto (1,1)$ and $\mathbf{e}_1 \mapsto (1,2)$, that is,

$$\mathbf{A} = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}, \qquad \det \mathbf{A} = 1 \neq 0.$$

Check: $\mathbf{A}\mathbf{e}_0 = (1,1)$, so $[1:0] \mapsto [1:1]$; $\mathbf{A}\mathbf{e}_1 = (1,2)$, so $[0:1] \mapsto [1:2]$; $\mathbf{A}(1,1) = (2,3)$, so $[1:1] \mapsto [2:3]$. By Theorem 21.7.5 no other projectivity does this, so every other correct answer is $\lambda\mathbf{A}$.

Exercise B2: General position.

Determine which of the following lists of points of $\mathbb{P}^2(\mathbb{Q})$ are in general position. Justify your answer.

(a) $[1:0:0]$, $[1:1:0]$, $[1:1:1]$, $[0:1:1]$.
(b) $[1:0:0]$, $[0:1:0]$, $[1:2:0]$, $[0:0:1]$.
(c) $[1:1:1]$, $[1:2:4]$, $[1:3:9]$, $[1:4:16]$.

Solution. Here $n = 2$, so general position for four points means every triple of representatives is independent, tested by a 3×3 determinant.

(a) The four determinants, in the order of the triples $(1,2,3)$, $(1,2,4)$, $(1,3,4)$, $(2,3,4)$, are

$$\det \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix} = 1, \quad \det \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix} = 1,$$
$$\det \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix} = 0, \quad \det \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix} = -1.$$

The third is zero, so the list is **not** in general position: $[1:0:0]$, $[1:1:1]$, $[0:1:1]$ are collinear, since $(1,1,1) = (1,0,0) + (0,1,1)$.

(b) Not in general position: $(1,2,0) = (1,0,0) + 2(0,1,0)$, so the first three points are collinear.

(c) In general position. The four representatives are $(1, t, t^2)$ for $t = 1,2,3,4$, so each triple gives a Vandermonde matrix, whose determinant is $\prod_{i<j}(t_j - t_i)$ (Theorem 6.8.1, and Corollary 6.8.2 for the conclusion). Explicitly, $t = 1,2,3$ gives $1 \cdot 2 \cdot 1 = 2$; $t = 1,2,4$ gives $1 \cdot 3 \cdot 2 = 6$; $t = 1,3,4$ gives $2 \cdot 3 \cdot 1 = 6$; $t = 2,3,4$ gives $1 \cdot 2 \cdot 1 = 2$. All are non-zero, so every triple is independent.

Exercise B3: Cross-ratio.

In $\mathbb{P}^1(\mathbb{Q})$ with the chart $[t:1] \mapsto t$, let A, B, C, D have parameters $1, 2, 4, 8$.

(a) Compute $(A, B; C, D)$.

(b) Compute the images of the four points under the projectivity induced by $\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$, and recompute the cross-ratio.

Solution.

(a) By Proposition 21.7.8,

$$(A, B; C, D) = \big[\,(4-1)(8-2) : (4-2)(8-1)\,\big] = [18 : 14] = [9 : 7].$$

(b) The matrix has determinant 1, and sends $[t : 1]$ to $[t : t+1]$, which in the chart is $t/(t+1)$. The four parameters become $\frac{1}{2}, \frac{2}{3}, \frac{4}{5}, \frac{8}{9}$. Then

$$\tfrac{4}{5} - \tfrac{1}{2} = \tfrac{3}{10}, \quad \tfrac{8}{9} - \tfrac{2}{3} = \tfrac{2}{9},$$
$$\tfrac{4}{5} - \tfrac{2}{3} = \tfrac{2}{15}, \quad \tfrac{8}{9} - \tfrac{1}{2} = \tfrac{7}{18},$$

so the cross-ratio is $\big[\tfrac{3}{10} \cdot \tfrac{2}{9} : \tfrac{2}{15} \cdot \tfrac{7}{18}\big] = \big[\tfrac{1}{15} : \tfrac{7}{135}\big] = [9 : 7]$, after multiplying both entries by 135. This agrees with (a), as Theorem 21.7.9 (a) requires.

21.7.7.3 C. Going deeper

Exercise C1: Sharp triple transitivity, and a count.

(a) Prove that for any two triples of pairwise distinct points of $\mathbb{P}^1(F)$ there is exactly one projectivity carrying the first to the second.

(b) Hence compute $|\mathrm{PGL}_2(\mathbb{F}_q)|$ for a finite field $\mathbb{F}_q$, and check your answer against $q = 2$ by listing the projectivities of $\mathbb{P}^1(\mathbb{F}_2)$.

Solution.

(a) On a line, $n = 1$, so $n+2 = 3$ and general position for three points means pairwise distinct (Definition 21.7.2). The statement is Theorem 21.7.5.

(b) By (a), $\mathrm{PGL}_2(\mathbb{F}_q)$ acts on the set of ordered triples of pairwise distinct points of $\mathbb{P}^1(\mathbb{F}_q)$ in such a way that exactly one group element carries any given triple to any other. Fixing one triple, the map $g \mapsto (g(A), g(B), g(C))$ is therefore a bijection from $\mathrm{PGL}_2(\mathbb{F}_q)$ onto the set of such triples. Now $\mathbb{P}^1(\mathbb{F}_q)$ has $q+1$ points: there are $q^2 - 1$ non-zero vectors in $\mathbb{F}_q^2$, and each point has exactly $q-1$ representatives, so the count is $(q^2-1)/(q-1) = q+1$. Hence

$$|\mathrm{PGL}_2(\mathbb{F}_q)| = (q+1)\,q\,(q-1).$$

For $q = 2$ this is $3 \cdot 2 \cdot 1 = 6$. And indeed $\mathbb{P}^1(\mathbb{F}_2)$ has the three points $[1 : 0]$, $[0 : 1]$, $[1 : 1]$; by (a) every permutation of them is realized by exactly one projectivity, giving $3! = 6$. (Consistently, $\mathrm{GL}_2(\mathbb{F}_2)$ has 6 elements and the scalars are only $\mathbf{I}_2$, so Π of Theorem 21.7.3 is injective here.)

Exercise C2: Rearranging the four points.

Let A, B, C be pairwise distinct points of a projective line and D a fourth point.

(a) Prove that $(B, A; C, D)$ is obtained from $(A, B; C, D) = [\lambda : \mu]$ by exchanging the two entries.

(b) Suppose all four points lie in a chart, with parameters a, b, c, d, and that $(A, B; C, D)$ is the scalar χ. Prove that $(A, C; B, D) = 1 - \chi$.

Solution.

(a) Use Proposition 21.7.8 with the representatives $\mathbf{a}, \mathbf{b}$ and the expansions $\mathbf{c} = c_1\mathbf{a} + c_2\mathbf{b}$, $\mathbf{d} = d_1\mathbf{a} + d_2\mathbf{b}$. Computing $(B, A; C, D)$ means expanding in the basis $(\mathbf{b}, \mathbf{a})$ instead, which exchanges the roles of the two coordinates: the coefficients of $\mathbf{c}$ are now (c_2, c_1) and those of $\mathbf{d}$ are (d_2, d_1). The formula gives $[\, d_2c_1 : d_1c_2 \,]$, the entries of $[\, d_1c_2 : d_2c_1 \,]$ exchanged.

(b) By Proposition 21.7.8 in the chart,

$$\chi = \frac{(c-a)(d-b)}{(c-b)(d-a)}, \qquad (A, C; B, D) = \frac{(b-a)(d-c)}{(b-c)(d-a)}.$$

Put both over the common denominator $(c-b)(d-a)$, noting $(b-c) = -(c-b)$:

$$\chi + (A, C; B, D) = \frac{(c-a)(d-b) - (b-a)(d-c)}{(c-b)(d-a)}.$$

Expand the numerator:

$$\begin{aligned}(c-a)(d-b) - (b-a)(d-c) &= cd - cb - ad + ab - bd + bc + ad - ac \\ &= cd + ab - bd - ac = (c-b)(d-a).\end{aligned}$$

Hence $\chi + (A, C; B, D) = 1$, as claimed.

Exercise C3: Cross-ratio characterizes projectivities of a line.

Let L and L' be projective lines over F and let $g\colon L \to L'$ be an **injection** such that

$$\big(g(A), g(B); g(C), g(D)\big) = (A, B; C, D)$$

for all $A, B, C, D \in L$ with A, B, C pairwise distinct. Prove that g is a projectivity.

Hint: pin g down on three points first.

Solution. Write $L = \mathbb{P}(U)$ with $\dim U = 2$ and pick a basis $(\mathbf{u}_1, \mathbf{u}_2)$ of U; the three points $[\mathbf{u}_1]$, $[\mathbf{u}_2]$, $[\mathbf{u}_1 + \mathbf{u}_2]$ are pairwise distinct, since no two of $\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_1 + \mathbf{u}_2$ are proportional. So we may choose pairwise distinct $A, B, C \in L$. Since g is injective, $g(A), g(B), g(C)$ are pairwise distinct. By Theorem 21.7.5 with $n = 1$ there is a unique projectivity $h\colon L \to L'$ with $h(A) = g(A)$, $h(B) = g(B)$, $h(C) = g(C)$.

Let $D \in L$. By the hypothesis on g and by Theorem 21.7.9 (a) applied to h,

$$\big(g(A), g(B); g(C), g(D)\big) = (A, B; C, D) = \big(h(A), h(B); h(C), h(D)\big).$$

The two triples on the outside are the same, namely $(g(A), g(B), g(C))$. Writing f' for the normalizing projectivity of that triple (Definition 21.7.3), the displayed equality reads $f'(g(D)) = f'(h(D))$, and f' is injective, so $g(D) = h(D)$. As D was arbitrary, $g = h$, a projectivity.

Note where each hypothesis went: injectivity of g was needed only to know that $g(A), g(B), g(C)$ are distinct, so that the cross-ratio hypothesis is applicable at all. Surjectivity was never assumed, and comes out at the end: $g = h$ and h is a bijection (Proposition 21.7.1).

21.8 Duality

Two facts about the projective plane sit side by side. Two distinct points lie on exactly one line; two distinct lines meet in exactly one point. Read either sentence aloud with "point" and "line" exchanged and you get the other. This is not a coincidence and it is not a philosophy: Chapter 4 already built the machine that produces it. A hyperplane of $\mathbb{P}(V)$ is the set of points killed by a linear functional, the functional is determined by the hyperplane up to a scalar, and so the hyperplanes of $\mathbb{P}(V)$ are themselves the points of a projective space, namely $\mathbb{P}(V^*)$. This section turns that observation into an inclusion-reversing dictionary between the projective subspaces of $\mathbb{P}(V)$ and those of $\mathbb{P}(V^*)$, gets the dimension bookkeeping right at both ends, and says exactly how much of the "duality principle" we are entitled to claim.

Throughout, F is an arbitrary field and V is a finite-dimensional vector space over F with $\dim V = n + 1 \geq 1$, so that $\mathbb{P}(V)$ has dimension n (Definition 21.6.1). No hypothesis on the characteristic is needed anywhere in this section, and no analysis is used. We keep the two extreme projective subspaces in play: $\mathbb{P}(\{\mathbf{0}\}) = \emptyset$, of dimension -1, and $\mathbb{P}(V)$ itself, of dimension n. The correspondence below exchanges them, and it is precisely at those two ends that a duality argument is easiest to get wrong.

21.8.1 Projective subspaces remember their subspaces

Everything rests on being able to move between a projective subspace $\mathbb{P}(U)$ and the subspace U it came from. That is the content of a short lemma, proved in Section 6 and recalled here because almost every proof below uses it.

Lemma 21.8.1 — Passing Between U and $\mathbb{P}(U)$

Let U, U_1, U_2 be subspaces of V.

(a) $\mathbb{P}(U_1) \subseteq \mathbb{P}(U_2)$ if and only if $U_1 \subseteq U_2$. In particular $U \mapsto \mathbb{P}(U)$ is injective, so a projective subspace determines its subspace.

(b) $\mathbb{P}(U_1 \cap U_2) = \mathbb{P}(U_1) \cap \mathbb{P}(U_2)$.

(c) $\mathbb{P}(U_1) \vee \mathbb{P}(U_2) = \mathbb{P}(U_1 + U_2)$, where $\vee$ is the join, the smallest projective subspace containing both (Proposition 21.6.5).

Proof. Part (a) is Lemma 21.6.4, and parts (b) and (c) are Proposition 21.6.5 (a) and (b), the latter being where $\vee$ was defined. ∎

One consequence will be used repeatedly: if $S \subseteq T$ are projective subspaces of the same finite

dimension, then $S = T$. Indeed $U_S \subseteq U_T$ by (a) and $\dim U_S = \dim U_T$, so $U_S = U_T$ by Theorem 1.6.8.

21.8.2 The points of the dual space are the hyperplanes

A **hyperplane** of $\mathbb{P}(V)$ is a projective subspace of dimension $n-1$, that is, $\mathbb{P}(H)$ for a hyperplane H of V in the sense of Definition 4.5.2. In $\mathbb{P}^2$ these are the lines; in $\mathbb{P}^3$, the planes.

Now the hook. A hyperplane of V is the kernel of a non-zero functional (Theorem 4.5.3), and the functional is determined by its kernel up to a scalar, which is the injectivity half of the next proposition. "A non-zero vector of V^*, up to a non-zero scalar" is exactly the description of a point of $\mathbb{P}(V^*)$. So the hyperplanes of $\mathbb{P}(V)$ are not merely a set: they are the points of a projective space of their own, of the same dimension.

The dual projective space is the space whose points are the hyperplanes of the original.

Definition 21.8.1 — Dual Projective Space

Let V be a finite-dimensional vector space over F with $\dim V = n + 1 \geq 1$. The **dual projective space** of $\mathbb{P}(V)$ is the projective space

$$\mathbb{P}(V^*)$$

of the dual space V^* (Definition 4.1.2). A point of $\mathbb{P}(V^*)$ is a class $[\varphi]$ with $\varphi \in V^*$ **non-zero**, and $[\varphi] = [\psi]$ exactly when $\psi = \lambda\varphi$ for some $\lambda \in F \setminus \{0\}$.

Its dimension is $\dim V^* - 1 = n$, by Corollary 4.1.4: *the dual projective space has the same dimension as the original.* That is worth pausing on, because the correspondence we are about to build reverses dimensions inside a space of unchanged size.

Non-example by minimal change. Take $\varphi = 0$. It is a perfectly good element of V^*, but $[\,0\,]$ is not a point of $\mathbb{P}(V^*)$ — the definition excludes the zero vector, as Definition 21.6.1 does. And indeed $\ker 0 = V$, which is not a hyperplane: it has codimension 0, not 1 (Definition 4.5.2). The clause "non-zero" is exactly what keeps the following bijection honest.

Proposition 21.8.2 — Points of the Dual Are Hyperplanes

Let $\dim V = n + 1 \geq 1$. The map

$$[\varphi] \longmapsto \mathbb{P}(\ker \varphi)$$

is a well-defined bijection from $\mathbb{P}(V^*)$ onto the set of hyperplanes of $\mathbb{P}(V)$.

Idea. Three checks. Well defined: proportional functionals have the same kernel. Surjective: a hyperplane $\mathbb{P}(H)$ has $\dim H^0 = 1$ by the annihilator count, so it is cut out by some non-zero functional. Injective: two functionals with the same kernel H both lie in the one-dimensional space H^0, so they are proportional. The counting does all the work.

Proof. Well defined. If $\varphi \neq 0$ then $\ker\varphi$ is a hyperplane of V by Theorem 4.5.3, so $\mathbb{P}(\ker\varphi)$ is a projective subspace of dimension $\dim\ker\varphi - 1 = n-1$, a hyperplane of $\mathbb{P}(V)$. If $[\psi] = [\varphi]$, then $\psi = \lambda\varphi$ with $\lambda \neq 0$, and $\psi(\mathbf{v}) = 0$ if and only if $\varphi(\mathbf{v}) = 0$, so $\ker\psi = \ker\varphi$.

Surjective. Let $\mathbb{P}(H)$ be a hyperplane of $\mathbb{P}(V)$, so $\dim H = n$. By Theorem 4.2.2, $\dim H^0 = (n+1) - n = 1$, so there is a non-zero $\varphi \in H^0$. Then $H \subseteq \ker\varphi$ by Definition 4.2.1, and both have dimension n — the second by Theorem 4.5.3 and Theorem 3.9.5 — so $H = \ker\varphi$ by Theorem 1.6.8.

Injective. Suppose $\ker\varphi = \ker\psi = H$ with $\varphi, \psi \neq 0$. Then $\varphi, \psi \in H^0$, which has dimension 1 as above. Two non-zero vectors of a one-dimensional space are proportional, so $\psi = \lambda\varphi$ with $\lambda \neq 0$, that is, $[\psi] = [\varphi]$.

■

In coordinates this is completely concrete. Take $V = F^{n+1}$ with coordinates $x_0, \dots, x_n$. By Theorem 4.1.1 every functional is $\varphi_{\mathbf{a}}(\mathbf{x}) = a_0x_0 + \cdots + a_nx_n$ for a unique $\mathbf{a} \in F^{n+1}$, and this identification is a linear isomorphism $F^{n+1} \to (F^{n+1})^*$. So a point of the dual plane is a class $[a_0 : \cdots : a_n]$, and the hyperplane it names is

$$\{\, [\mathbf{x}] \in \mathbb{P}^n(F) \;:\; a_0x_0 + \cdots + a_nx_n = 0 \,\}.$$

The equation is homogeneous, so it does not matter which representative $\mathbf{x}$ we substitute; and scaling $\mathbf{a}$ does not change the solution set. Both scalings are exactly the ones the projective spaces divide out.

Example. (A line and its point)

In $\mathbb{P}^2(\mathbb{Q})$, find the point of the dual plane naming the line through $[1:1:0]$ and $[0:1:1]$. Then find the point where the lines $x_0 - x_1 + x_2 = 0$ and $x_0 + x_2 = 0$ meet.

Solution. The line. Its subspace is $U = \operatorname{span}\big((1,1,0),(0,1,1)\big)$, of dimension 2. By Theorem 4.2.2, $\dim U^0 = 3 - 2 = 1$, so one non-zero functional does it. We need $a_0 + a_1 = 0$ and $a_1 + a_2 = 0$, whose solutions are the multiples of $\mathbf{a} = (1,-1,1)$. Check: $1-1+0 = 0$ and $0-1+1 = 0$. So the line is $x_0 - x_1 + x_2 = 0$, named by the dual point $[1:-1:1]$.

The meet. Dually, we need $\mathbf{x}$ with $x_0 - x_1 + x_2 = 0$ and $x_0 + x_2 = 0$. Subtracting, $x_1 = 0$; then $x_0 = -x_2$. The solution space is spanned by $(-1,0,1)$, so the two lines meet in the single point $[-1:0:1]$. Check: $-1 - 0 + 1 = 0$ and $-1 + 1 = 0$.

The two computations are the same computation, run in V and in V^*. That is the whole of duality in one example.

Warning. **There is no canonical duality between $\mathbb{P}(V)$ and itself.** The rule "the point $[a_0 : a_1 : a_2]$ names the line $a_0x_0 + a_1x_1 + a_2x_2 = 0$" looks like a self-duality of $\mathbb{P}^2(F)$, but it depends on the coordinates. In $\mathbb{P}^2(\mathbb{Q})$ the rule assigns to $[1:0:1]$ the line $x_0 + x_2 = 0$. Change coordinates by $y_0 = x_0$, $y_1 = x_1$, $y_2 = 2x_2$. The same point is $[1:0:2]$ in the new coordinates, and the same rule now assigns to it the line $y_0 + 2y_2 = 0$, that is, $x_0 + 4x_2 = 0$. These are different lines: the point $[1:0:-1]$ lies on the first, since $1 - 1 = 0$, and not on the second, since $1 - 4 = -3 \neq 0$. What is canonical is the correspondence between $\mathbb{P}(V)$ and $\mathbb{P}(V^*)$, not one between $\mathbb{P}(V)$ and itself. Identifying

the two requires a choice — a basis, or a non-degenerate form, which is how the pole and polar of a conic will be built in Section 10 of this chapter.

21.8.3 The duality correspondence

We now extend $[\varphi] \mapsto \mathbb{P}(\ker \varphi)$ from hyperplanes to all projective subspaces. The right tool is the annihilator, and we keep Chapter 4's notation: for a subspace $U \subseteq V$, $U^0 = \{\varphi \in V^* : \varphi(\mathbf{u}) = 0 \text{ for all } \mathbf{u} \in U\}$ (Definition 4.2.1).

For a projective subspace $S = \mathbb{P}(U)$ of $\mathbb{P}(V)$, define

$$S^0 := \mathbb{P}\big(U^0\big) \subseteq \mathbb{P}(V^*).$$

This is well defined because S determines U, by Lemma 21.8.1 (a).

Before the theorem, the dimension bookkeeping, because it is the step where such a correspondence is usually stated wrongly. Projective dimension is one less than linear dimension. So from $\dim U + \dim U^0 = n + 1$ we get

$$(\dim S + 1) + (\dim S^0 + 1) = n + 1, \qquad \text{that is} \qquad \dim S^0 = n - 1 - \dim S.$$

Test it at both ends. If $S = \emptyset$, so $U = \{\mathbf{0}\}$ and $\dim S = -1$, the formula gives $\dim S^0 = n$, and indeed $\{\mathbf{0}\}^0 = V^*$, so $S^0 = \mathbb{P}(V^*)$. If $S = \mathbb{P}(V)$, with $\dim S = n$, the formula gives -1, and indeed $V^0 = \{0\}$, so $S^0 = \emptyset$. A point ($\dim S = 0$) goes to a hyperplane ($\dim S^0 = n - 1$), and a hyperplane goes to a point, agreeing with Proposition 21.8.2. The formula is symmetric in the sense that $d \mapsto n - 1 - d$ is its own inverse on $\{-1, 0, \dots, n\}$.

Theorem 21.8.3 — The Duality Correspondence

Let $\dim V = n + 1 \geq 1$, and let S, T be projective subspaces of $\mathbb{P}(V)$, the empty set and $\mathbb{P}(V)$ included. Then:

(a) $\dim S^0 = n - 1 - \dim S$;
(b) $S \subseteq T$ if and only if $T^0 \subseteq S^0$;
(c) $(S \vee T)^0 = S^0 \cap T^0$ and $(S \cap T)^0 = S^0 \vee T^0$;
(d) $S \mapsto S^0$ is a bijection from the set of projective subspaces of $\mathbb{P}(V)$ onto the set of projective subspaces of $\mathbb{P}(V^*)$.

Idea. Every part is a Chapter 4 statement about annihilators, translated through Lemma 21.8.1, with the dimension shifted by one at each end. The only part that needs thought is the reverse implication in (b) and the surjectivity in (d): both go up a level to V^{**} and come back with Corollary 4.3.4, which is available because V is finite-dimensional.

Proof. Write $S = \mathbb{P}(U)$ and $T = \mathbb{P}(U')$, which is legitimate and unambiguous by Lemma 21.8.1 (a).

(a) By Theorem 4.2.2, $\dim U^0 = (n + 1) - \dim U$. Hence

$$\dim S^0 = \dim U^0 - 1 = n - \dim U = n - (\dim S + 1) = n - 1 - \dim S.$$

(b) ($\Rightarrow$) If $S \subseteq T$, then $U \subseteq U'$ by Lemma 21.8.1 (a), so $(U')^0 \subseteq U^0$ by Theorem 4.2.3

(a), so $T^0 \subseteq S^0$ by the same lemma. ($\Leftarrow$) Suppose $T^0 \subseteq S^0$, so $(U')^0 \subseteq U^0$. Applying Theorem 4.2.3 (a) inside V^* gives $U^{00} \subseteq (U')^{00}$. By Corollary 4.3.4, $U^{00} = \mathrm{ev}_V(U)$ and $(U')^{00} = \mathrm{ev}_V(U')$, so $\mathrm{ev}_V(U) \subseteq \mathrm{ev}_V(U')$. Since ev_V is injective (Theorem 4.3.2), $U \subseteq U'$, and $S \subseteq T$.

(c) By Lemma 21.8.1 (c), $S \vee T = \mathbb{P}(U + U')$, and $(U + U')^0 = U^0 \cap (U')^0$ by Theorem 4.2.3 (c). Applying $\mathbb{P}(\cdot)$ and Lemma 21.8.1 (b),

$$(S \vee T)^0 = \mathbb{P}\big(U^0 \cap (U')^0\big) = \mathbb{P}(U^0) \cap \mathbb{P}\big((U')^0\big) = S^0 \cap T^0.$$

For the second identity, $S \cap T = \mathbb{P}(U \cap U')$ by Lemma 21.8.1 (b), and $(U \cap U')^0 = U^0 + (U')^0$ by Theorem 4.2.3 (d), which needs V finite-dimensional. Applying $\mathbb{P}(\cdot)$ and part (c) of the same lemma gives $(S \cap T)^0 = S^0 \vee T^0$.

(d) *Injective.* If $S^0 = T^0$ then $U^0 = (U')^0$ by Lemma 21.8.1 (a), so $U = U'$ by Corollary 4.3.5, so $S = T$.

Surjective. Let $R = \mathbb{P}(W)$ be a projective subspace of $\mathbb{P}(V^*)$, where W is a subspace of V^*. Put

$$U \coloneqq \mathrm{ev}_V^{-1}\big(W^0\big) = \{\mathbf{v} \in V : \varphi(\mathbf{v}) = 0 \text{ for every } \varphi \in W\},$$

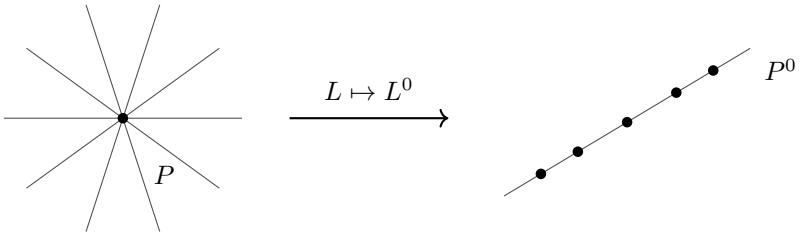
a subspace of V: it is the intersection of the kernels $\ker \varphi$ over $\varphi \in W$, each a subspace by Theorem 3.2.1, and an intersection of subspaces is a subspace by Theorem 1.2.2. Since ev_V is surjective (Theorem 4.3.2), $\mathrm{ev}_V(U) = W^0$. By Corollary 4.3.4, $(U^0)^0 = U^{00} = \mathrm{ev}_V(U) = W^0$. Now U^0 and W are subspaces of the finite-dimensional space V^* with the same annihilator, so $U^0 = W$ by Corollary 4.3.5 applied in V^*. Hence $\mathbb{P}(U)^0 = \mathbb{P}(W) = R$. This proves the theorem.

■

Quick check. Let S be a line in $\mathbb{P}^3(F)$. What is $\dim S^0$, and what kind of object is S^0? What if S is a point?

Solution. Here $n = 3$ and $\dim S = 1$, so $\dim S^0 = 3 - 1 - 1 = 1$ by Theorem 21.8.3 (a): S^0 is again a line, this time in the dual space $\mathbb{P}((F^4)^*)$. Lines in $\mathbb{P}^3$ are self-dual in dimension, which is one reason they are the interesting objects there. If instead S is a point, $\dim S = 0$ and $\dim S^0 = 3 - 1 - 0 = 2$: a plane in the dual space. Concretely, it is the set of all planes of $\mathbb{P}^3$ through that point.

Remark. The last sentence of the solution is the general reading of the correspondence. Since $S \subseteq P$ if and only if $P^0 \subseteq S^0$, the hyperplanes containing S are exactly the points of S^0: *a projective subspace is named, on the dual side, by the family of hyperplanes that contain it.* For a point, that family is a hyperplane's worth of hyperplanes.



in $\mathbb{P}(V)$ in $\mathbb{P}(V^*)$

each line L through P is one point L^0 of the dual plane,
and those points fill the line P^0

21.8.4 Dualizing twice

Applying the correspondence twice lands in $\mathbb{P}(V^{**})$, not back in $\mathbb{P}(V)$. Chapter 4 already told us what to do: the evaluation map is a canonical isomorphism $V \to V^{**}$, and it induces a projectivity.

Theorem 21.8.4 — Dualizing Twice Returns the Original

Let $\dim V = n+1 \geq 1$. The evaluation map $\mathrm{ev}_V \colon V \to V^{**}$ is an isomorphism (Theorem 4.3.2), so it induces a projectivity $[\mathrm{ev}_V] \colon \mathbb{P}(V) \to \mathbb{P}(V^{**})$ (Definition 21.7.1). For every projective subspace S of $\mathbb{P}(V)$,

$$S^{00} = [\mathrm{ev}_V](S),$$

so that under the identification $\mathbb{P}(V) = \mathbb{P}(V^{**})$ given by $[\mathrm{ev}_V]$ we have $S^{00} = S$. Moreover the inverse of the bijection of Theorem 21.8.3 (d) is $R \mapsto [\mathrm{ev}_V]^{-1}\big(R^0\big)$.

Proof. Write $S = \mathbb{P}(U)$. By the definition of the correspondence applied twice, $S^{00} = \mathbb{P}\big((U^0)^0\big) = \mathbb{P}\big(\mathrm{ev}_V(U)\big)$, using Corollary 4.3.4. By Proposition 21.7.2, $\mathbb{P}(\mathrm{ev}_V(U)) = [\mathrm{ev}_V](\mathbb{P}(U)) = [\mathrm{ev}_V](S)$.

For the last statement, let R be a projective subspace of $\mathbb{P}(V^*)$ and put $S \coloneqq [\mathrm{ev}_V]^{-1}(R^0)$, a projective subspace of $\mathbb{P}(V)$ by Proposition 21.7.2 applied to $[\mathrm{ev}_V]^{-1}$. Then $[\mathrm{ev}_V](S) = R^0$, so by the first part $(S^0)^0 = S^{00} = R^0$. Both S^0 and R are projective subspaces of $\mathbb{P}(V^*)$, and Theorem 21.8.3 (d) applied to the space V^* says that the correspondence there is injective, so $S^0 = R$.

■

Duality is also compatible with the maps of Section 07, which is what makes it more than a coordinate trick.

Proposition 21.8.5 — Duality and Projectivities

Let $T \colon V \to W$ be an isomorphism of $(n+1)$-dimensional spaces, with dual map $T' \colon W^* \to V^*$ (Definition 4.4.1), which is an isomorphism by Theorem 4.4.1 (d). Then

for every projective subspace S of $\mathbb{P}(V)$,

$$\big([T](S)\big)^0 = \big[(T')^{-1}\big](S^0).$$

Proof. Write $S = \mathbb{P}(U)$, so $[T](S) = \mathbb{P}(T(U))$ by Proposition 21.7.2. For $\psi \in W^*$,

$$\psi \in T(U)^0 \iff \psi(T\mathbf{u}) = 0 \text{ for all } \mathbf{u} \in U \iff (T'\psi)(\mathbf{u}) = 0 \text{ for all } \mathbf{u} \in U,$$

the second step by Definition 4.4.1, and the right-hand condition says $T'\psi \in U^0$. Hence $T(U)^0 = (T')^{-1}(U^0)$. Applying $\mathbb{P}(\cdot)$ and Proposition 21.7.2 to the isomorphism $(T')^{-1}$ gives the claim.

■

21.8.5 The duality principle

We can now state precisely what "every theorem has a dual" amounts to in this book.

Theorem 21.8.6 — The Duality Principle

Let $\dim V = n+1 \geq 1$, and let $S \mapsto S^0$ be the correspondence of Theorem 21.8.3, from the projective subspaces of the n-dimensional space $\mathbb{P}(V)$ onto those of the n-dimensional space $\mathbb{P}(V^*)$. Let R, S, T be projective subspaces of $\mathbb{P}(V)$ and let d be an integer. Then:

(a) $S \subseteq T$ if and only if $T^0 \subseteq S^0$; and $S = T$ if and only if $S^0 = T^0$;
(b) $\dim S = d$ if and only if $\dim S^0 = n - 1 - d$;
(c) $R = S \vee T$ if and only if $R^0 = S^0 \cap T^0$;
(d) $R = S \cap T$ if and only if $R^0 = S^0 \vee T^0$;
(e) as S runs over all projective subspaces of $\mathbb{P}(V)$, the subspace S^0 runs exactly once over all projective subspaces of $\mathbb{P}(V^*)$.

Proof.

(a) The first claim is Theorem 21.8.3 (b), and the second follows by applying it in both directions, or from injectivity in Theorem 21.8.3 (d).
(b) By Theorem 21.8.3 (a), $\dim S^0 = n - 1 - \dim S$. So $\dim S = d$ gives $\dim S^0 = n - 1 - d$; conversely $\dim S^0 = n - 1 - d$ gives $n - 1 - \dim S = n - 1 - d$, hence $\dim S = d$.
(c) ($\Rightarrow$) is Theorem 21.8.3 (c). ($\Leftarrow$) If $R^0 = S^0 \cap T^0 = (S \vee T)^0$, then $R = S \vee T$ by the equality clause of (a).
(d) The same argument with the second identity of Theorem 21.8.3 (c).
(e) This is Theorem 21.8.3 (d).

■

How the principle is used, and what we have not proved. Every clause of Theorem 21.8.6 is an "if and only if", and by (e) the correspondence is a bijection between the two supplies of subspaces. So a proved statement about $\mathbb{P}(V)$ whose hypotheses and conclusion are built **only** from the relations $\subseteq$ and $=$, the operations $\vee$ and $\cap$, and the dimensions of the subspaces involved, can be translated clause by clause: reverse every inclusion, exchange $\vee$ with $\cap$, and replace every dimension d by $n-1-d$. The translated statement then holds in $\mathbb{P}(V^*)$; and since every $(n+1)$-dimensional space W satisfies $W \cong (W^*)^*$ (Theorem 4.3.2), a statement true in $\mathbb{P}(V^*)$ for **every** V is true in $\mathbb{P}(W)$ for every W, because projectivities preserve all of this structure (Proposition 21.7.2).

This is a recipe, carried out below on the statements this chapter makes, and each carrying out is a proof. It is **not** a theorem here. To make "for every statement built only from ..." itself a theorem, one has to define a formal language of incidence statements and induct on the way a statement is built, and this book has set up no such language. So we claim the principle only as a working method, and we prove each dual statement we use.

Corollary 21.8.7 — Two Points, Two Lines

Let $\dim V = 3$, so that $\mathbb{P}(V)$ is a projective plane.

(a) Two distinct points of $\mathbb{P}(V)$ lie on exactly one line.

(b) Two distinct lines of $\mathbb{P}(V)$ meet in exactly one point.

Idea. Prove (a) by hand: two distinct points have independent representatives, so their span is a plane in V and a line in $\mathbb{P}(V)$. Then get (b) from (a) by the dictionary, in $\mathbb{P}(V^*)$, which is a projective plane of its own. Section 06 already proved both statements directly from the dimension formula (Proposition 21.6.8, Corollary 21.6.7). The point of doing (b) again this way is that duality delivers it with no geometry at all: every step is a clause of Theorem 21.8.6 with $n = 2$.

Proof.

(a) Let $P = [\mathbf{v}] \neq Q = [\mathbf{w}]$. The list $(\mathbf{v}, \mathbf{w})$ is independent: otherwise $\mathbf{w}$ would be a scalar multiple of $\mathbf{v}$, giving $P = Q$. So $\operatorname{span}(\mathbf{v}, \mathbf{w})$ has dimension 2, and by Lemma 21.8.1 (c), $P \vee Q = \mathbb{P}(\operatorname{span}(\mathbf{v}, \mathbf{w}))$, a projective subspace of dimension 1, that is, a line containing both points. If L is any line containing P and Q, then $P \vee Q \subseteq L$ because the join is the smallest such subspace, and both have dimension 1, so $L = P \vee Q$ by the consequence noted after Lemma 21.8.1.

(b) Here $n = 2$. Let $L_1 \neq L_2$ be lines of $\mathbb{P}(V)$. By Theorem 21.8.6 (b), $\dim L_i^0 = 2 - 1 - 1 = 0$, so L_1^0 and L_2^0 are points of $\mathbb{P}(V^*)$, and they are distinct by the equality clause of Theorem 21.8.6 (a). The space $\mathbb{P}(V^*)$ is a projective plane, since $\dim V^* = 3$ by Corollary 4.1.4, so part (a), applied in $\mathbb{P}(V^*)$, says that $L_1^0 \vee L_2^0$ is a line, of dimension 1.

By Theorem 21.8.6 (d), $(L_1 \cap L_2)^0 = L_1^0 \vee L_2^0$. Hence $\dim(L_1 \cap L_2)^0 = 1$, and Theorem 21.8.6 (b) read backwards gives $\dim(L_1 \cap L_2) = 2-1-1 = 0$. A projective subspace of dimension 0 is a single point. This proves that L_1 and L_2 meet in exactly one point.

■

The same bookkeeping shows that the dimension formula of Theorem 21.6.6 is **self-dual**: re-

placing each of $\dim(S \vee T)$, $\dim(S \cap T)$, $\dim S$, $\dim T$ by $n-1$ minus itself and exchanging $\vee$ with $\cap$ turns

$$\dim(S \vee T) + \dim(S \cap T) = \dim S + \dim T$$

into $(n-1-\dim(S\cap T))+(n-1-\dim(S\vee T)) = (n-1-\dim S)+(n-1-\dim T)$, which is the same equation after canceling $2(n-1)$. A self-dual theorem is one whose dual gives nothing new, and that is a useful thing to be able to detect.

Warning. **The dual of "point" is not "line"; it is "hyperplane", and which dimension that is depends on n.** In the projective plane, $n=2$, and $2-1-0=1$: points dualize to lines, which is why Corollary 21.8.7 looks like a swap of the two words. In $\mathbb{P}^3$, $n=3$, so points dualize to **planes** $(3-1-0=2)$ and lines dualize to lines $(3-1-1=1)$. The correct dual of "two distinct points lie on a unique line" in $\mathbb{P}^3$ is "two distinct planes meet in a unique line", and that is true. The careless dual, "two distinct lines meet in a point", is **false** in $\mathbb{P}^3$: the lines $\mathbb{P}(\operatorname{span}(\mathbf{e}_0,\mathbf{e}_1))$ and $\mathbb{P}(\operatorname{span}(\mathbf{e}_2,\mathbf{e}_3))$ have $\operatorname{span}(\mathbf{e}_0,\mathbf{e}_1)\cap\operatorname{span}(\mathbf{e}_2,\mathbf{e}_3)=\{\mathbf{0}\}$, so they do not meet at all. Always compute $n-1-d$; never translate by the words alone.

Pole and polar — the correspondence a conic sets up between the points and the lines of a plane — is the one piece of duality that needs a quadratic form rather than only the annihilator. It is treated in Section 10 of this chapter, where conics are, and nothing in this section depends on it.

21.8.6 Exercises

21.8.6.1 A. Check your understanding

Exercise A1.

(a) Define the dual projective space of $\mathbb{P}(V)$, and say what its dimension is.

(b) Let S be a plane in $\mathbb{P}^4(F)$. Compute $\dim S^0$.

(c) True or false, with a reason: the duality correspondence of Theorem 21.8.3 is a bijection from the points of $\mathbb{P}(V)$ to the points of $\mathbb{P}(V)$.

(d) In $\mathbb{P}^2$, what is the dual of the statement "three distinct points are collinear"?

(e) What are $\emptyset^0$ and $\mathbb{P}(V)^0$?

Solution.

(a) It is $\mathbb{P}(V^*)$, the projective space of the dual space (Definition 21.8.1). If $\dim\mathbb{P}(V)=n$, then $\dim\mathbb{P}(V^*)=n$ as well, by Corollary 4.1.4.

(b) A plane has dimension 2 and $n=4$, so $\dim S^0 = 4-1-2=1$: a line in the dual space.

(c) False, twice over. It is a bijection between **all** projective subspaces of $\mathbb{P}(V)$ and all projective subspaces of $\mathbb{P}(V^*)$, and it sends points of $\mathbb{P}(V)$ to hyperplanes of $\mathbb{P}(V^*)$, not to points; and its target is $\mathbb{P}(V^*)$, not $\mathbb{P}(V)$ (see the warning after Example (A line and its point)).

(d) With $n=2$, points dualize to lines and a line dualizes to a point. "Three distinct points lie on one line" becomes "three distinct lines pass through one point", that is, the three lines are concurrent.

(e) $\emptyset^0 = \mathbb{P}(\{\mathbf{0}\}^0) = \mathbb{P}(V^*)$, of dimension $n = n - 1 - (-1)$; and $\mathbb{P}(V)^0 = \mathbb{P}(V^0) = \mathbb{P}(\{0\}) = \emptyset$, of dimension $-1 = n - 1 - n$.

21.8.6.2 B. Practice

Exercise B1: Lines and dual points.

Work in $\mathbb{P}^2(\mathbb{Q})$.

(a) Find the dual point of the line through $[1 : 2 : 1]$ and $[0 : 1 : 3]$.

(b) Find the point where the lines $x_0 + x_1 - x_2 = 0$ and $2x_0 - x_1 = 0$ meet.

Solution.

(a) We need $\mathbf{a} = (a_0, a_1, a_2)$ with $a_0 + 2a_1 + a_2 = 0$ and $a_1 + 3a_2 = 0$. From the second, $a_1 = -3a_2$; substituting, $a_0 = -2a_1 - a_2 = 6a_2 - a_2 = 5a_2$. Taking $a_2 = 1$ gives $\mathbf{a} = (5, -3, 1)$, so the line is $5x_0 - 3x_1 + x_2 = 0$ and the dual point is $[5 : -3 : 1]$. Check: $5 - 6 + 1 = 0$ and $0 - 3 + 3 = 0$. By Theorem 4.2.2 the solution space is one-dimensional, so this is the only answer up to scaling.

(b) Solve $x_0 + x_1 - x_2 = 0$ and $2x_0 - x_1 = 0$. The second gives $x_1 = 2x_0$, and then $x_2 = x_0 + x_1 = 3x_0$. Taking $x_0 = 1$, the meet is $[1 : 2 : 3]$. Check: $1 + 2 - 3 = 0$ and $2 - 2 = 0$. The solution space is one-dimensional, consistent with Corollary 21.8.7 (b).

Exercise B2: Dimension bookkeeping.

Let $n = 5$, so $\mathbb{P}(V) = \mathbb{P}^5(F)$. For each of the following S, give $\dim S^0$, and say which of the two is larger.

(a) S a point.

(b) S a line.

(c) S of dimension 2.

(d) S a hyperplane.

(e) $S = \emptyset$.

Then determine whether there is any S with $\dim S^0 = \dim S$. Justify your answer.

Solution. By Theorem 21.8.3 (a), $\dim S^0 = 5 - 1 - \dim S = 4 - \dim S$.

(a) $\dim S = 0$, $\dim S^0 = 4$; the dual is larger. (b) 1 and 3; the dual is larger. (c) 2 and 2; equal. (d) 4 and 0; the original is larger. (e) -1 and 5; the dual is larger.

For the last part, $\dim S^0 = \dim S$ means $4 - \dim S = \dim S$, that is, $\dim S = 2$. So the self-dual dimension in $\mathbb{P}^5$ is 2, and part (c) is an instance. In general $\dim S^0 = \dim S$ forces $2 \dim S = n - 1$, which has a solution exactly when n is odd.

Exercise B3: Dualize a statement.

For each statement about $\mathbb{P}^3(F)$, write the dual statement, using Theorem 21.8.6 with $n = 3$, and say whether both are true.

(a) A point and a line not through it lie in exactly one plane.

(b) Three planes with no common line meet in at most one point.

Solution. With $n = 3$, the dimension rule is $d \mapsto 2 - d$: points (0) and planes (2) exchange, lines (1) stay lines, $\emptyset$ (-1) and the whole space (3) exchange. Joins become meets.

(a) Dual: *a plane and a line not contained in it meet in exactly one point.* Both are true. For the original: if $P \not\subseteq L$ then $P \cap L = \emptyset$, so by Theorem 21.6.6 $\dim(P \vee L) = 0 + 1 - (-1) = 2$, a plane, and it is unique because any plane containing both contains $P \vee L$ and has the same dimension. Dualizing each clause by Theorem 21.8.6 gives the dual statement, which is therefore also true; directly, if the plane Π does not contain L, then $\Pi \vee L$ has dimension 3, so $\dim(\Pi \cap L) = 2 + 1 - 3 = 0$.

(b) Dualize clause by clause, as the warning after Corollary 21.8.7 insists. The hypothesis "the three planes contain no common line" reads: there is no L with $\dim L = 1$ and $L \subseteq \Pi_1 \cap \Pi_2 \cap \Pi_3$. Writing $P_i = \Pi_i^0$, which are points by Theorem 21.8.6 (b), and using (a) and (d) of that theorem, the hypothesis becomes: there is no L' with $\dim L' = 1$ and $P_1 \vee P_2 \vee P_3 \subseteq L'$, that is, the three points are **not** collinear. The conclusion "$\Pi_1 \cap \Pi_2 \cap \Pi_3$ has dimension at most 0" becomes "$P_1 \vee P_2 \vee P_3$ has dimension at least 2". So the dual statement is: *three points not on a common line span a projective subspace of dimension at least* 2, that is, they span a plane. Both are true: three non-collinear points $[\mathbf{v}_1], [\mathbf{v}_2], [\mathbf{v}_3]$ have independent representatives, since a dependence would put all three in a subspace of dimension at most 2 and hence on a common line, so their join has dimension 2 by Lemma 21.8.1 (c). The original then follows by dualizing back.

21.8.6.3 C. Going deeper

Exercise C1: Counting in a finite projective plane.

Let q be a prime power and $F = \mathbb{F}_q$.

(a) Show that a projective space of dimension d over $\mathbb{F}_q$ has $(q^{d+1} - 1)/(q - 1)$ points.

(b) Deduce that $\mathbb{P}^2(\mathbb{F}_q)$ has as many lines as points, and that every point lies on exactly $q + 1$ lines.

Solution.

(a) Such a space is $\mathbb{P}(U)$ with $\dim U = d + 1$. The set $U \setminus \{\mathbf{0}\}$ has $q^{d+1} - 1$ elements, and two non-zero vectors give the same point exactly when they differ by a scalar in $\mathbb{F}_q \setminus \{0\}$, a set of size $q - 1$. So each point has exactly $q - 1$ representatives, and the number of points is $(q^{d+1} - 1)/(q - 1)$.

(b) By Proposition 21.8.2 the lines of $\mathbb{P}^2(\mathbb{F}_q)$ are in bijection with the points of $\mathbb{P}((\mathbb{F}_q^3)^*)$, which by Corollary 4.1.4 is again a projective plane over $\mathbb{F}_q$. So by (a) with $d = 2$ both counts are $N \coloneqq q^2 + q + 1$.

For the last claim, fix a point P. The lines of $\mathbb{P}^2(\mathbb{F}_q)$ containing P are, by the remark after Theorem 21.8.3, exactly the points of P^0, and $\dim P^0 = 2-1-0 = 1$ by Theorem 21.8.3 (a). So by (a) with $d = 1$ there are $q+1$ of them. As a check, count the incident pairs (P, L) with $P \in L$ in two ways: each line is a projective space of dimension 1 and so carries $q+1$ points, giving $N(q+1)$ pairs, and the other count gives $N(q+1)$ as well.

Exercise C2: A form makes a self-duality.

Let β be a non-degenerate symmetric bilinear form on V, with $\dim V = n+1$.

(a) Show that $R_\beta \colon V \to V^*$, $\mathbf{v} \mapsto \beta(\cdot, \mathbf{v})$, is an isomorphism, and deduce that it induces a projectivity $[R_\beta] \colon \mathbb{P}(V) \to \mathbb{P}(V^*)$.

(b) Hence define, for a projective subspace S of $\mathbb{P}(V)$, a projective subspace $S^\perp$ of $\mathbb{P}(V)$ with $\dim S^\perp = n - 1 - \dim S$, and show that the assignment $S \mapsto S^\perp$ is an inclusion-reversing bijection of the set of projective subspaces of $\mathbb{P}(V)$ with itself.

(c) Give an example over $\mathbb{R}$ with $n = 2$ in which $S \subseteq S^\perp$ for some point S, and explain why this cannot happen if β is positive definite.

Solution.

(a) By Proposition 13.1.2, β is non-degenerate exactly when R_β is an isomorphism $V \to V^*$. A projectivity is induced by any isomorphism (Definition 21.7.1), so $[R_\beta]$ is one.

(b) Define $S^\perp := [R_\beta]^{-1}(S^0)$. This is a projective subspace of $\mathbb{P}(V)$ by Proposition 21.7.2, of the same dimension as S^0, namely $n-1-\dim S$ by Theorem 21.8.3 (a). Since $[R_\beta]^{-1}$ is a bijection preserving inclusion (Proposition 21.7.2) and $S \mapsto S^0$ is an inclusion-reversing bijection onto the projective subspaces of $\mathbb{P}(V^*)$ (Theorem 21.8.3 (b), (d)), the composite is an inclusion-reversing bijection of the projective subspaces of $\mathbb{P}(V)$ with themselves.

(c) Take $V = \mathbb{R}^3$ and $\beta(\mathbf{x}, \mathbf{y}) = x_0y_0 + x_1y_1 - x_2y_2$, which is non-degenerate since its matrix $\operatorname{diag}(1, 1, -1)$ is invertible. Let $\mathbf{v} = (1, 0, 1)$, so $\beta(\mathbf{v}, \mathbf{v}) = 1 + 0 - 1 = 0$, and let $S = \{[\mathbf{v}]\}$. Then $R_\beta(\mathbf{v}) = \beta(\cdot, \mathbf{v})$ kills $\mathbf{v}$, so $[\mathbf{v}] \in S^\perp$, that is, $S \subseteq S^\perp$. If β were positive definite, then $\beta(\mathbf{v}, \mathbf{v}) > 0$ for every $\mathbf{v} \neq \mathbf{0}$, so no non-zero vector is annihilated by its own functional, and $S \subseteq S^\perp$ is impossible for a point S. The non-zero vectors with $\beta(\mathbf{v}, \mathbf{v}) = 0$ are the isotropic ones of Definition 13.7.1, taken for the quadratic form $q(\mathbf{v}) = \beta(\mathbf{v}, \mathbf{v})$; they are exactly the points lying on their own duals.

Exercise C3: What the correspondence does to a chain.

Let $\dim V = n+1$ and let

$$\emptyset = S_{-1} \subsetneq S_0 \subsetneq S_1 \subsetneq \cdots \subsetneq S_n = \mathbb{P}(V)$$

be projective subspaces with $\dim S_d = d$ for each d.

(a) Prove that $S_n^0 \subsetneq S_{n-1}^0 \subsetneq \cdots \subsetneq S_{-1}^0$ is again such a chain, and identify $\dim S_d^0$.

(b) Deduce that $S \mapsto S^0$ carries the chains of this shape in $\mathbb{P}(V)$ bijectively to those in $\mathbb{P}(V^*)$, and that it reverses their order.

Solution.

(a) By Theorem 21.8.6 (a), $S_d \subseteq S_{d+1}$ gives $S^0_{d+1} \subseteq S^0_d$, and the inclusion is strict: if $S^0_{d+1} = S^0_d$ then $S_{d+1} = S_d$ by the equality clause, contradicting strictness. By Theorem 21.8.6 (b), $\dim S^0_d = n-1-d$. As d runs from -1 to n, the value $n-1-d$ runs from n down to -1, taking each value once. So writing $T_e \coloneqq S^0_{n-1-e}$ gives $\dim T_e = e$ and $T_{-1} \subsetneq T_0 \subsetneq \cdots \subsetneq T_n$, a chain of the same shape in $\mathbb{P}(V^*)$.

(b) The assignment is injective because $S \mapsto S^0$ is (Theorem 21.8.6 (e)), applied term by term. It is surjective: given a chain $T_{-1} \subsetneq T_0 \subsetneq \cdots \subsetneq T_n$ with $\dim T_e = e$ in $\mathbb{P}(V^*)$, set $S_d \coloneqq [\mathrm{ev}_V]^{-1}\big(T^0_{n-1-d}\big)$, which by Theorem 21.8.4 is the unique projective subspace of $\mathbb{P}(V)$ with $S^0_d = T_{n-1-d}$. By Theorem 21.8.6 (b), $\dim S_d = n-1-(n-1-d) = d$; and if $d < d'$ then $n-1-d > n-1-d'$, so $T_{n-1-d} \supsetneq T_{n-1-d'}$, whence $S_d \subsetneq S_{d'}$ by Theorem 21.8.6 (a). So (S_d) is a chain of the required shape whose image is the given one, and the order has been reversed.

21.9 Desargues and Pappus

Two theorems from the drawing board, both of them older than coordinates. Both speak only of points, lines and incidence: no lengths, no angles, nothing a projective transformation could disturb. Both are proved here by one algebraic move, the one that makes projective arguments short — choosing, out of the whole line of vectors that represents a point, the single vector that makes the hypothesis into an equation.

21.9.1 Perspective from a point, perspective from a line

Draw a triangle on a sheet of glass and let a lamp cast its shadow on the floor. The two triangles that result have their corresponding vertices joined by three lines through the lamp. That is the first of the two relations below. The second is what the same picture looks like when you attend to the sides instead of the vertices: corresponding sides, extended, meet the ground in three points, and those three points lie on one line.

Both relations need the words "the line through two points", and there is exactly one: distinct points $A = [\mathbf{a}]$ and $B = [\mathbf{b}]$ of $\mathbb{P}(V)$ have independent representatives and lie on the unique line $\mathbb{P}(\mathrm{span}(\mathbf{a}, \mathbf{b}))$, by Proposition 21.6.8. We write AB for it, and we use that description of it, as $\mathbb{P}(\mathrm{span}(\mathbf{a}, \mathbf{b}))$, in every proof below.

Definition 21.9.1 — Triangles, and the Two Perspectives

Let $\dim V = 3$, so that $\mathbb{P}(V)$ is a projective plane (Definition 21.6.3). A **triangle** in $\mathbb{P}(V)$ is an ordered triple (A, B, C) of **non-collinear** points, called its **vertices**; its **sides** are the three lines AB, BC, CA.

Let (A, B, C) and (A', B', C') be triangles with $A \neq A'$, $B \neq B'$ and $C \neq C'$. They are:

(a) **perspective from a point** if some point O lies on **all three** of the lines AA',

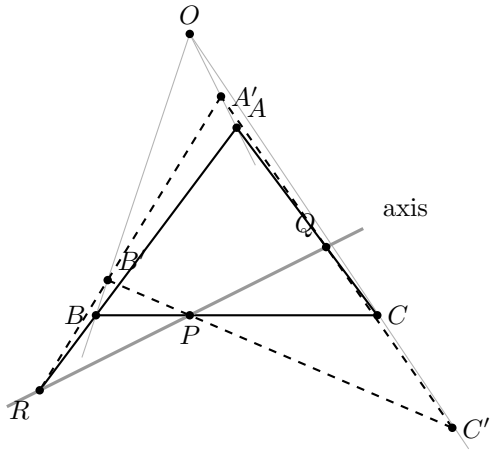
BB', CC'; such an O is a **center**;

(b) **perspective from a line** if the three pairs of corresponding sides $\{AB, A'B'\}$, $\{BC, B'C'\}$, $\{CA, C'A'\}$ consist of **distinct** lines and the three intersection points

$$AB \cap A'B', \qquad BC \cap B'C', \qquad CA \cap C'A'$$

are collinear; a line through all three is an **axis**.

In (b) each intersection is a single point: two **distinct** lines in a projective plane meet in exactly one point (Corollary 21.6.7). That is why the clause "distinct in each pair" is part of the definition and not an afterthought; without it the phrase "the point $AB \cap A'B'$" names nothing.



The picture shows both relations at once: the three gray rays make the triangles perspective from O, and the three marked points $R = AB \cap A'B'$, $P = BC \cap B'C'$, $Q = CA \cap C'A'$ lie on the thick line. Desargues's theorem says that this coincidence is no coincidence.

Warning. **Two corresponding sides may be the same line, and then part (b) is not even a statement.** Take a line ℓ, four distinct points A, B, A', B' on it and a point O on it, and any $C \notin \ell$. Fix representatives $\mathbf{o}$ of O and $\mathbf{c}$ of C and put $C' = [\mathbf{o} + \mathbf{c}]$, a point of the line OC other than O and C; it does not lie on ℓ, since $OC \neq \ell$ and the two meet only at O (Corollary 21.6.7). The triples (A, B, C) and (A', B', C') are triangles, the six vertices are distinct, and the three lines AA', BB', CC' all pass through O. But $AB = \ell = A'B'$, so "the point $AB \cap A'B'$" does not exist. Exercise (C3: Why the side hypothesis is there) writes this out in coordinates. The hypothesis that rules it out is the one in the theorem below: no vertex of either triangle lies on a side of the other.

21.9.2 Choosing the representatives

A point of $\mathbb{P}(V)$ is a whole line of vectors, and every proof has to pick one vector per point. The pick is free, and freedom used well is the whole art. Here the hypothesis is three collinearities, and each of them becomes a clean equation as soon as the two representatives involved are scaled against each other.

Lemma 21.9.1 — Scaling Three Collinear Points

Let $W \subseteq V$ be a 2-dimensional subspace and let O, A, A' be three **distinct** points of the line $\mathbb{P}(W)$. Let $\mathbf{o}$ be any non-zero vector representing O. Then there are vectors $\mathbf{a}$ representing A and $\mathbf{a}'$ representing A' with

$$\mathbf{a}' = \mathbf{a} + \mathbf{o}.$$

Idea. Two distinct points of a line give a basis of W, so the third is a combination of them. Both coefficients are non-zero, precisely because the third point is neither of the first two; and scaling the two representatives by the right amounts turns that combination into a sum with coefficients 1 and 1.

Proof. Pick any non-zero $\mathbf{a}_0$ representing A. Since $O \neq A$, the pair $(\mathbf{o}, \mathbf{a}_0)$ is independent, and it lies in W with $\dim W = 2$, so it is a basis of W. As $A' \in \mathbb{P}(W)$, a representative $\mathbf{a}'_0$ of A' can be written

$$\mathbf{a}'_0 = \mu\,\mathbf{a}_0 + \nu\,\mathbf{o}, \qquad \mu, \nu \in F.$$

Here $\nu \neq 0$: otherwise $\mathbf{a}'_0 = \mu\mathbf{a}_0$ with $\mu \neq 0$, giving $A' = A$. And $\mu \neq 0$: otherwise $\mathbf{a}'_0 = \nu\mathbf{o}$ with $\nu \neq 0$, giving $A' = O$. Both are excluded because the three points are distinct.

Put $\mathbf{a} \coloneqq (\mu/\nu)\,\mathbf{a}_0$ and $\mathbf{a}' \coloneqq (1/\nu)\,\mathbf{a}'_0$, which is legitimate since μ/ν and $1/\nu$ are non-zero scalars, so $\mathbf{a}$ still represents A and $\mathbf{a}'$ still represents A'. Then

$$\mathbf{a}' = \tfrac{1}{\nu}\big(\mu\mathbf{a}_0 + \nu\mathbf{o}\big) = \tfrac{\mu}{\nu}\mathbf{a}_0 + \mathbf{o} = \mathbf{a} + \mathbf{o}.$$

This proves the lemma. ∎

It is Lemma 21.7.4 for $n = 1$, with the one common scalar spent on fixing $\mathbf{o}$ first. The lemma is used three times in a row, always with the **same** $\mathbf{o}$. That is the point: $\mathbf{o}$ is chosen once and never rescaled again, while each pair $(\mathbf{a}, \mathbf{a}')$, $(\mathbf{b}, \mathbf{b}')$, $(\mathbf{c}, \mathbf{c}')$ is scaled to match it.

Quick check. In the lemma, which conclusions survive if we drop the hypothesis $A' \neq O$? And if we drop $A' \neq A$?

Solution. Neither survives. If $A' = O$ we may take $\mathbf{a}'_0 = \mathbf{o}$, so $\mu = 0$; and the conclusion fails, because every representative $\mathbf{a}'$ of $A' = O$ is a multiple of $\mathbf{o}$, so $\mathbf{a} = \mathbf{a}' - \mathbf{o}$ would lie in $\operatorname{span}(\mathbf{o})$, forcing $\mathbf{a} = \mathbf{0}$ or $A = [\mathbf{a}] = O$, and both are impossible. If $A' = A$ we may take $\mathbf{a}'_0 = \mathbf{a}_0$, so $\nu = 0$, and $\mathbf{a}' = \mathbf{a} + \mathbf{o}$ would say that two representatives of the same point A differ by $\mathbf{o}$; subtracting, $\mathbf{o}$ would be a multiple of $\mathbf{a}$, making $O = A$, again excluded. Each of the two scalars μ, ν is guarded by exactly one of the two hypotheses.

21.9.3 Desargues's theorem

The forward half of Desargues's theorem needs less than the full configuration, and stating it with its minimal hypotheses is what makes it reusable: the converse will apply it to a **different** pair of triangles built from the same picture.

Lemma 21.9.2 — Perspective from a Point Gives an Axis

Let $\dim V = 3$. Let (A, B, C) and (A', B', C') be triangles in $\mathbb{P}(V)$ with $A \neq A'$, $B \neq B'$, $C \neq C'$, and suppose:

(i) some point O, **distinct from all six vertices**, lies on each of AA', BB', CC';
(ii) $AB \neq A'B'$, $BC \neq B'C'$ and $CA \neq C'A'$.

Then the three points $AB \cap A'B'$, $BC \cap B'C'$, $CA \cap C'A'$ are collinear.

Idea. Fix one representative $\mathbf{o}$ of O. By Lemma 21.9.1 the three collinearities can be written as $\mathbf{a}' = \mathbf{a} + \mathbf{o}$, $\mathbf{b}' = \mathbf{b} + \mathbf{o}$, $\mathbf{c}' = \mathbf{c} + \mathbf{o}$ for suitable representatives. Subtract two of them and $\mathbf{o}$ cancels: $\mathbf{a} - \mathbf{b} = \mathbf{a}' - \mathbf{b}'$. One vector, lying in $\operatorname{span}(\mathbf{a}, \mathbf{b})$ and in $\operatorname{span}(\mathbf{a}', \mathbf{b}')$ at once, so its point lies on both AB and $A'B'$. The three such vectors add to $\mathbf{0}$, so they span at most a plane; the triangles being genuine keeps them from collapsing to a line, so they span exactly a plane, and a plane of V is a line of $\mathbb{P}(V)$.

Proof. Fix a non-zero $\mathbf{o}$ representing O. The points O, A, A' are distinct, by (i) and by $A \neq A'$, and they are collinear, since $O \in AA'$ and $AA' = \mathbb{P}(W)$ with $\dim W = 2$. So Lemma 21.9.1 gives representatives $\mathbf{a}$ of A and $\mathbf{a}'$ of A' with $\mathbf{a}' = \mathbf{a} + \mathbf{o}$. The same lemma, with the **same** $\mathbf{o}$, gives $\mathbf{b}' = \mathbf{b} + \mathbf{o}$ and $\mathbf{c}' = \mathbf{c} + \mathbf{o}$.

Subtracting, $\mathbf{a} - \mathbf{b} = \mathbf{a}' - \mathbf{b}'$. Now $\mathbf{a} - \mathbf{b} \neq \mathbf{0}$, since $\mathbf{a} = \mathbf{b}$ would give $A = B$, contradicting that (A, B, C) is a triangle. Since $\mathbf{a} - \mathbf{b} \in \operatorname{span}(\mathbf{a}, \mathbf{b})$ and $AB = \mathbb{P}(\operatorname{span}(\mathbf{a}, \mathbf{b}))$, the point $[\mathbf{a} - \mathbf{b}]$ lies on AB; since $\mathbf{a} - \mathbf{b} = \mathbf{a}' - \mathbf{b}' \in \operatorname{span}(\mathbf{a}', \mathbf{b}')$, it lies on $A'B'$ as well. By (ii) these two lines are distinct, so by Corollary 21.6.7 they meet in exactly one point, and therefore

$$AB \cap A'B' = [\mathbf{a} - \mathbf{b}].$$

The same argument, with the letters advanced cyclically, gives $BC \cap B'C' = [\mathbf{b} - \mathbf{c}]$ and $CA \cap C'A' = [\mathbf{c} - \mathbf{a}]$.

Let $U = \operatorname{span}(\mathbf{a} - \mathbf{b},\ \mathbf{b} - \mathbf{c},\ \mathbf{c} - \mathbf{a})$. The three vectors sum to $\mathbf{0}$, so $U = \operatorname{span}(\mathbf{a} - \mathbf{b},\ \mathbf{b} - \mathbf{c})$ and $\dim U \leq 2$. Moreover $\dim U = 2$: if $\mathbf{a} - \mathbf{b} = t(\mathbf{b} - \mathbf{c})$ for some $t \in F$, then $\mathbf{a} = (1 + t)\mathbf{b} - t\mathbf{c} \in \operatorname{span}(\mathbf{b}, \mathbf{c})$, so A would lie on BC, contradicting that (A, B, C) is a triangle; and $\mathbf{b} - \mathbf{c} \neq \mathbf{0}$ for the same reason as before. So $\mathbb{P}(U)$ is a line, and it contains all three points. This proves the lemma.

■

Now the configuration of Definition 21.9.1, with the one extra hypothesis that kept the warning above at bay.

Theorem 21.9.3 — Desargues's Theorem

Let $\dim V = 3$ and let (A, B, C) and (A', B', C') be triangles in $\mathbb{P}(V)$ such that

(i) the six vertices are distinct, and
(ii) no vertex of either triangle lies on a side of the other.

Then the two triangles are perspective from a point if and only if they are perspective

from a line.

Idea. ① The hypotheses (i) and (ii) are exactly what is needed to feed Lemma 21.9.2: (ii) forces corresponding sides apart, and — less obviously — it also forces a center to miss all six vertices, because a center sitting on a vertex would drag a vertex of one triangle onto a side of the other. ② For the converse there is no second theorem to prove: the same lemma is applied to the auxiliary triangles (A, A', Q) and (B, B', P), which are perspective from R because the axis passes through R. Their corresponding sides meet in $AA' \cap BB'$, in C' and in C; collinearity of those three puts $AA' \cap BB'$ on the line CC', which is concurrency.

Proof. Throughout, (ii) is used in the form: none of A, B, C lies on $A'B'$, $B'C'$ or $C'A'$, and none of A', B', C' lies on AB, BC or CA.

First, the three pairs of corresponding sides are distinct. If $AB = A'B'$ then $A' \in AB$, contrary to (ii); the other two pairs are the same argument with the letters advanced.

($\Rightarrow$) Suppose O lies on AA', BB', CC'. We check that O is none of the six vertices. If $O = A$, then $A \in BB'$; since $A \neq B$, the line through A and B is AB, and it contains B', so $B' \in AB$, contrary to (ii). If $O = B$, then $B \in AA'$ gives $A' \in AB$ in the same way, and if $O = C$ then $C \in AA'$ gives $A' \in CA$; both contradict (ii). If $O = A'$, then $A' \in BB'$; since $A' \neq B'$, the line through them is $A'B'$, and it contains B, so $B \in A'B'$, contrary to (ii). If $O = B'$ then $B' \in AA'$ gives $A \in A'B'$, and if $O = C'$ then $C' \in AA'$ gives $A \in C'A'$; both contradict (ii). So Lemma 21.9.2 applies, and its conclusion is that the two triangles are perspective from a line.

($\Leftarrow$) Suppose the three points

$$R = AB \cap A'B', \qquad P = BC \cap B'C', \qquad Q = CA \cap C'A'$$

are collinear. We apply Lemma 21.9.2 to the triangles (A, A', Q) and (B, B', P), with center R, and verify its hypotheses one at a time.

The points Q and P are not vertices. If $Q = A$ then $A \in C'A'$, and if $Q = A'$ then $A' \in CA$; both contradict (ii). Likewise $P \neq B$ and $P \neq B'$.

Both triples are triangles. Suppose A, A', Q were collinear. Since $Q \in CA$ and $Q \neq A$, the line QA is CA; so $AA' = QA = CA$, whence $A' \in CA$, contrary to (ii). The triple (B, B', P) is handled the same way.

Corresponding vertices are distinct. $A \neq B$ and $A' \neq B'$ by (i). If $Q = P$, that point lies on CA and on CB; these two lines are distinct (else A, B, C would be collinear) and both contain C, so by Corollary 21.6.7 they meet only at C, giving $Q = C$ and hence $C \in C'A'$, contrary to (ii).

The center R is none of the six vertices A, A', Q, B, B', P. If $R = A$ then $A \in A'B'$; if $R = B$ then $B \in A'B'$; if $R = A'$ then $A' \in AB$; if $R = B'$ then $B' \in AB$. All four contradict (ii). If $R = Q$, then this point lies on AB and on CA, two distinct lines through A, so $R = A$, already excluded; if $R = P$, the same argument with AB and BC gives $R = B$, also excluded.

R lies on the three joins. It lies on AB and on $A'B'$ by definition. Since $Q \neq P$, the line QP is defined, and it contains R because P, Q, R are collinear.

Corresponding sides of the two auxiliary triangles are distinct. If $AA' = BB'$, this one

line contains A and B, hence equals AB, and then $A' \in AB$, contrary to (ii). Next, $Q \in C'A'$ and $Q \neq A'$ give $A'Q = C'A'$, and $P \in B'C'$ with $P \neq B'$ give $B'P = B'C'$; these are distinct, since $C'A' = B'C'$ would make A', B', C' collinear. Finally $QA = CA$ and $PB = CB$, distinct for the same reason.

By Lemma 21.9.2 the three points

$$X = AA' \cap BB',$$
$$A'Q \cap B'P = C'A' \cap B'C' = C',$$
$$QA \cap PB = CA \cap CB = C$$

are collinear, the last two evaluations being Corollary 21.6.7 applied to two distinct lines with an evident common point. Since $C \neq C'$ by (i), the line through C and C' is CC', and collinearity puts X on it. So X lies on AA', on BB' and on CC': the triangles are perspective from the point X. This proves the theorem.

■

Two routes to Desargues's theorem are standard. One embeds the plane in $\mathbb{P}^3$, moves one triangle off the plane, and uses that two distinct planes of $\mathbb{P}^3$ meet in a line; Exercise (C1: Desargues in space) carries that route out. The proof above is the other, purely two-dimensional route, and the step that decides whether it works is the scaling of Lemma 21.9.1 — one representative **o** fixed first, every other representative matched to it afterwards.

Remark. The two halves of the theorem are dual statements: interchange "point" with "line", "lies on" with "passes through", and "perspective from a point" becomes "perspective from a line". Read through the correspondence of Theorem 21.8.3, the converse should therefore be the dual of the direct half rather than an independent fact; **we do not carry that dualization out here**, and nothing depends on it. The proof above does not use it; it derives the converse from the direct half by applying it to a second pair of triangles, so that nothing rests on how far the duality principle of Theorem 21.8.6 can be pushed as a general statement.

Example. (Desargues with exact coordinates)

In $\mathbb{P}^2(\mathbb{Q})$ take $O = [1 : 1 : 1]$ and the triangle $A = [1 : 0 : 0]$, $B = [0 : 1 : 0]$, $C = [0 : 0 : 1]$, and on the three lines through O take

$$A' = [3 : 1 : 1], \qquad B' = [1 : 4 : 1], \qquad C' = [1 : 1 : 2].$$

Verify the hypotheses, scale the representatives as in the proof, and find the axis.

Solution. Each primed point does lie on the corresponding line: $(3,1,1) = 2(1,0,0) + (1,1,1)$, $(1,4,1) = 3(0,1,0) + (1,1,1)$, and $(1,1,2) = (0,0,1) + (1,1,1)$. Both triples are triangles, since $(\mathbf{e}_0, \mathbf{e}_1, \mathbf{e}_2)$ is a basis and

$$\det \begin{pmatrix} 3 & 1 & 1 \\ 1 & 4 & 1 \\ 1 & 1 & 2 \end{pmatrix} = 17 \neq 0.$$

The six vertices are distinct. No vertex of either lies on a side of the other: the sides of ABC are the coordinate lines $\{x_2 = 0\}$, $\{x_0 = 0\}$, $\{x_1 = 0\}$, and each primed point has

all three coordinates non-zero; in the other direction the primed sides are

$$A'B' = \{3x_0 + 2x_1 - 11x_2 = 0\},$$
$$B'C' = \{7x_0 - x_1 - 3x_2 = 0\},$$
$$C'A' = \{-x_0 + 5x_1 - 2x_2 = 0\},$$

and no coefficient in any of them is zero, so none of $\mathbf{e}_0, \mathbf{e}_1, \mathbf{e}_2$ satisfies any of the three equations.

Now scale. With $\mathbf{o} = (1,1,1)$ the relation $\mathbf{a}'_0 = 2\mathbf{a}_0 + \mathbf{o}$ has $\mu = 2$, $\nu = 1$, so the lemma takes $\mathbf{a} = 2(1,0,0) = (2,0,0)$ and $\mathbf{a}' = (3,1,1)$; similarly $\mathbf{b} = (0,3,0)$, $\mathbf{b}' = (1,4,1)$ and $\mathbf{c} = (0,0,1)$, $\mathbf{c}' = (1,1,2)$. Each check is one subtraction:

$$\mathbf{a}' - \mathbf{a} = \mathbf{b}' - \mathbf{b} = \mathbf{c}' - \mathbf{c} = (1,1,1) = \mathbf{o}.$$

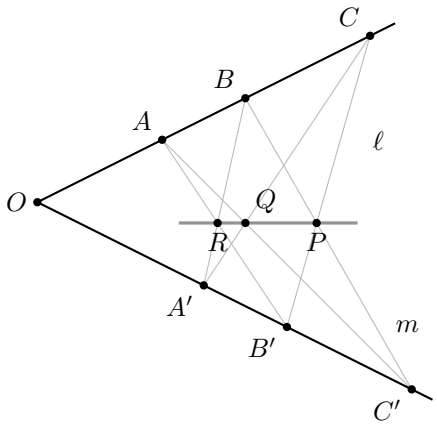
The three intersection points are therefore

$$R = [\mathbf{a} - \mathbf{b}] = [2 : -3 : 0],$$
$$P = [\mathbf{b} - \mathbf{c}] = [0 : 3 : -1],$$
$$Q = [\mathbf{c} - \mathbf{a}] = [-2 : 0 : 1],$$

and indeed $(2,-3,0) + (0,3,-1) + (-2,0,1) = \mathbf{0}$. A linear form vanishing on the first two is $3x_0 + 2x_1 + 6x_2$, and it vanishes on the third as well, so the axis is the line $\{3x_0 + 2x_1 + 6x_2 = 0\}$.

21.9.4 Pappus's theorem

Desargues's theorem uses two triangles. Pappus's uses two lines, with three points on each, and concludes that three points built by cross-joining them lie on a line. Nothing is assumed about the two triples beyond being distinct and avoiding the one point the two lines share.



The six thin lines are the cross-joins; they meet in pairs at R, Q and P, and the theorem says those three points always lie on one line, the thick one.

Theorem 21.9.4 — Pappus's Theorem

Let $\dim V = 3$, let ℓ and m be **distinct** lines of $\mathbb{P}(V)$ and let O be their common point. Let A, B, C be three **distinct** points of ℓ, none equal to O, and let A', B', C' be three **distinct** points of m, none equal to O. Then the three points

$$\begin{aligned} R &= AB' \cap A'B, \\ Q &= AC' \cap A'C, \\ P &= BC' \cap B'C \end{aligned}$$

exist and are collinear.

Idea. Coordinates, in the one basis the data offers: the common point O and one direction along each line. Every point of the configuration then costs a single parameter, each cross-join is a 2×2 system, and the three answers come out as explicit vectors. What finishes the proof is not a determinant but an identity visible on the page: the vector for Q is the sum of the vectors for P and R.

Proof. Write $\ell = \mathbb{P}(U)$ and $m = \mathbb{P}(W)$ with $\dim U = \dim W = 2$. Since $\ell \neq m$ we have $U \neq W$ (Lemma 21.6.4), and two distinct subspaces of the same dimension satisfy $U \not\subseteq W$, so $U + W$ strictly contains W and has dimension $3 = \dim V$. By the dimension formula Theorem 1.7.3, $\dim(U \cap W) = 2 + 2 - 3 = 1$. Thus $U \cap W = \operatorname{span}(\mathbf{o})$ for a non-zero $\mathbf{o}$, and $O = [\mathbf{o}]$ is the unique common point of ℓ and m.

Choose $\mathbf{u} \in U \setminus \operatorname{span}(\mathbf{o})$ and $\mathbf{w} \in W \setminus \operatorname{span}(\mathbf{o})$. Then $(\mathbf{o}, \mathbf{u})$ is a basis of U and $(\mathbf{o}, \mathbf{w})$ is a basis of W, and $(\mathbf{u}, \mathbf{w}, \mathbf{o})$ is a basis of V: it has three members and spans $U + W = V$. Every point of ℓ other than O is represented by a vector $s\mathbf{u} + t\mathbf{o}$ with $s \neq 0$, hence, after dividing by s, by exactly one vector of the form $\mathbf{u} + t\mathbf{o}$; and likewise on m. So there are scalars with

$$\begin{aligned} A &= [\mathbf{u} + a\mathbf{o}], & B &= [\mathbf{u} + b\mathbf{o}], & C &= [\mathbf{u} + c\mathbf{o}], \\ A' &= [\mathbf{w} + a'\mathbf{o}], & B' &= [\mathbf{w} + b'\mathbf{o}], & C' &= [\mathbf{w} + c'\mathbf{o}], \end{aligned}$$

where a, b, c are distinct and a', b', c' are distinct, because the representatives above are uniquely determined by the points.

The three intersections exist. The lines AB' and $A'B$ are defined, since $A \neq B'$ and $A' \neq B$: a point of ℓ other than O is not a point of m, as $\ell \cap m = \{O\}$. They are distinct: if $AB' = A'B$, this line would contain A and B, two distinct points of ℓ, hence be ℓ; then $A' \in \ell \cap m = \{O\}$, contradicting $A' \neq O$. So $R = AB' \cap A'B$ is a single point (Corollary 21.6.7), and the same argument gives Q and P.

Computing R. A vector in $\operatorname{span}(\mathbf{u} + a\mathbf{o},\ \mathbf{w} + b'\mathbf{o})$ has the form

$$\lambda\mathbf{u} + \mu\mathbf{w} + (\lambda a + \mu b')\mathbf{o},$$

and a vector in $\operatorname{span}(\mathbf{w} + a'\mathbf{o},\ \mathbf{u} + b\mathbf{o})$ has the form $\lambda'\mathbf{u} + \mu'\mathbf{w} + (\lambda' b + \mu' a')\mathbf{o}$. A non-zero vector lying in both must have $\lambda = \lambda'$ and $\mu = \mu'$, the triple $(\mathbf{u}, \mathbf{w}, \mathbf{o})$ being a basis, and then

$$\lambda a + \mu b' = \lambda b + \mu a' \quad \Longleftrightarrow \quad \lambda(a - b) = \mu(a' - b').$$

Taking $\lambda = a' - b'$ and $\mu = a - b$ solves it. The resulting vector is the same read in either span: in the first the coefficient of $\mathbf{o}$ is $(a' - b')a + (a - b)b' = aa' - bb'$, and in the

second it is $(a'-b')b+(a-b)a' = aa'-bb'$ as well. So

$$\mathbf{r} = (a'-b')\,\mathbf{u} + (a-b)\,\mathbf{w} + (aa'-bb')\,\mathbf{o}$$

lies on both lines, and it is non-zero since $a \neq b$. The two lines being distinct, Corollary 21.6.7 makes $[\mathbf{r}]$ their unique common point: $R = [\mathbf{r}]$. Advancing the letters, $Q = [\mathbf{q}]$ and $P = [\mathbf{p}]$ with

$$\mathbf{q} = (a'-c')\,\mathbf{u} + (a-c)\,\mathbf{w} + (aa'-cc')\,\mathbf{o},$$
$$\mathbf{p} = (b'-c')\,\mathbf{u} + (b-c)\,\mathbf{w} + (bb'-cc')\,\mathbf{o}.$$

The finish. Comparing the three displayed vectors coordinate by coordinate in the basis $(\mathbf{u}, \mathbf{w}, \mathbf{o})$,

$$\mathbf{p} + \mathbf{r} - \mathbf{q} = \mathbf{0}.$$

So $\operatorname{span}(\mathbf{p}, \mathbf{q}, \mathbf{r}) = \operatorname{span}(\mathbf{p}, \mathbf{r})$ has dimension at most 2, and it has dimension at least 1 since $\mathbf{r} \neq \mathbf{0}$. Any subspace of dimension 1 or 2 is contained in some 2-dimensional subspace Z of V, and then $\mathbb{P}(Z)$ is a line containing P, Q and R. This proves the theorem.

■

The hypotheses did exactly three jobs, and it is worth saying which. That $\ell \neq m$ gave the basis. That none of the six points is O let every one of them be written as $\mathbf{u} + t\mathbf{o}$ or $\mathbf{w} + t\mathbf{o}$ with the leading coefficient 1; a point equal to O has no such representative, and the parametrization would break down. That a, b, c are distinct and a', b', c' are distinct made the six cross-joins exist and the three vectors non-zero. Nothing else was needed — in particular the six points may interleave along their two lines in any order, and no further non-degeneracy hypothesis is required.

Remark. Over $\mathbb{F}_2$ the theorem is vacuous: a projective line over $\mathbb{F}_2$ has $2+1=3$ points (Proposition 21.6.9), so after removing O only two remain and three distinct points A, B, C cannot be chosen. Over $\mathbb{F}_3$ the hypotheses can just be met, and Exercise (C2: Pappus over the two smallest fields) checks the conclusion there by hand.

Example. (Pappus with exact coordinates)

In $\mathbb{P}^2(\mathbb{Q})$ let $\ell = \{x_1 = 0\}$ and $m = \{x_0 = 0\}$, and take

$$A = [1:0:0], \quad B = [1:0:1], \quad C = [1:0:2],$$
$$A' = [0:1:0], \quad B' = [0:1:1], \quad C' = [0:1:3].$$

Find R, Q, P and the line through them.

Solution. Here $\mathbf{o} = \mathbf{e}_2$, $\mathbf{u} = \mathbf{e}_0$, $\mathbf{w} = \mathbf{e}_1$, and the parameters are $a=0$, $b=1$, $c=2$, $a'=0$, $b'=1$, $c'=3$. The formulas of the proof give

$$\mathbf{r} = (0-1)\mathbf{e}_0 + (0-1)\mathbf{e}_1 + (0-1)\mathbf{e}_2 = -(1,1,1),$$
$$\mathbf{q} = (0-3)\mathbf{e}_0 + (0-2)\mathbf{e}_1 + (0-6)\mathbf{e}_2 = -(3,2,6),$$
$$\mathbf{p} = (1-3)\mathbf{e}_0 + (1-2)\mathbf{e}_1 + (1-6)\mathbf{e}_2 = -(2,1,5),$$

so $R = [1:1:1]$, $Q = [3:2:6]$, $P = [2:1:5]$, and $\mathbf{p} + \mathbf{r} - \mathbf{q} = \mathbf{0}$ as it must be. A linear form vanishing at R and P is $4x_0 - 3x_1 - x_2$, and $4\cdot 3 - 3\cdot 2 - 6 = 0$, so all three

lie on the line $\{4x_0 - 3x_1 - x_2 = 0\}$.

As a check on the formulas, compute R directly: AB' is spanned by $(1,0,0)$ and $(0,1,1)$, so it is $\{x_1 = x_2\}$; $A'B$ is spanned by $(0,1,0)$ and $(1,0,1)$, so it is $\{x_0 = x_2\}$. Their common point is $[1:1:1]$.

21.9.5 What the two theorems measure

Both theorems have been proved here inside $\mathbb{P}(V)$ for a vector space V over a field F, and the proofs used the field only through its arithmetic. It is worth recording what happens if either assumption is loosened, because the answers are among the most quoted facts in the subject — and because this book has built neither the tools to prove them nor the language to state them carefully.

Remark. An axiomatic **projective plane** is a set of points and lines satisfying incidence axioms, with no vector space given in advance. Hilbert's coordinatization theory attaches an algebraic system to such a plane and reads geometric axioms off it. Two results of that theory: Desargues's theorem holds in a plane exactly when the plane comes from a **division ring** — a field except that multiplication need not commute — and Pappus's theorem holds exactly when that division ring is **commutative**, hence a field. Consequently Pappus implies Desargues, a purely geometric implication first proved by Hessenberg; and there are non-Desarguesian planes, the Moulton plane being the standard example. None of this is proved here, and nothing in this book depends on it: we have not constructed division rings, and "projective plane" has meant $\mathbb{P}(V)$ throughout. The honest summary is that our proof of Pappus's theorem multiplied scalars in whatever order was convenient — and that commuting them is exactly what the general theory says cannot be dispensed with.

21.9.6 Exercises

21.9.6.1 A. Check your understanding

Exercise A1.

(a) Define "perspective from a point" and "perspective from a line" for two triangles in a projective plane.

(b) In Lemma 21.9.1, which hypothesis makes $\mu \neq 0$ and which makes $\nu \neq 0$?

(c) State Theorem 21.9.3, with both of its hypotheses on the configuration.

(d) True or false, with a reason: in Theorem 21.9.4 the six points are required to be pairwise distinct.

(e) Name the one place in the proof of Theorem 21.9.4 where the hypothesis $\ell \neq m$ is used.

Solution.

(a) Definition 21.9.1: perspective from a point means some point lies on all three lines AA', BB', CC'; perspective from a line means the three pairs of corresponding sides are pairs of distinct lines and their three intersection points are collinear.

(b) The hypothesis $A' \neq O$ makes $\mu \neq 0$, and $A' \neq A$ makes $\nu \neq 0$.

(c) Two triangles whose six vertices are distinct and with no vertex of either lying on a side of the other are perspective from a point if and only if they are perspective from a line.

(d) True, though it is stated in two pieces: A, B, C are required distinct and A', B', C' are required distinct, and no point of $\ell \setminus \{O\}$ can equal a point of $m \setminus \{O\}$, since $\ell \cap m = \{O\}$. So all six are distinct.

(e) In the first paragraph, to get $\dim(U \cap W) = 1$ and hence the basis $(\mathbf{u}, \mathbf{w}, \mathbf{o})$. If $\ell = m$ then $U = W$ and there is no such basis.

21.9.6.2 B. Practice

Exercise B1: A Desargues configuration.

In $\mathbb{P}^2(\mathbb{Q})$ let $O = [1:1:1]$, $A = [1:0:0]$, $B = [0:1:0]$, $C = [0:0:1]$, and

$$A' = [0:1:1], \qquad B' = [1:0:1], \qquad C' = [1:1:0].$$

Check that each primed point lies on the corresponding line through O, scale the representatives as in Lemma 21.9.2, and compute the axis.

Solution. $(0,1,1) = -(1,0,0) + (1,1,1)$, and similarly $(1,0,1) = -(0,1,0) + (1,1,1)$ and $(1,1,0) = -(0,0,1) + (1,1,1)$. In each case $\mu = -1$ and $\nu = 1$, so Lemma 21.9.1 takes $\mathbf{a} = -\mathbf{e}_0$, $\mathbf{a}' = (0,1,1)$, and likewise $\mathbf{b} = -\mathbf{e}_1$, $\mathbf{b}' = (1,0,1)$, $\mathbf{c} = -\mathbf{e}_2$, $\mathbf{c}' = (1,1,0)$. Each difference $\mathbf{a}' - \mathbf{a}$ is $(1,1,1)$, as required.

Hence

$$\begin{aligned} AB \cap A'B' &= [\mathbf{a} - \mathbf{b}] = [-1:1:0], \\ BC \cap B'C' &= [\mathbf{b} - \mathbf{c}] = [0:-1:1], \\ CA \cap C'A' &= [\mathbf{c} - \mathbf{a}] = [1:0:-1], \end{aligned}$$

and the three vectors sum to $\mathbf{0}$. A linear form vanishing at the first two is $x_0 + x_1 + x_2$, which also vanishes at the third, so the axis is $\{x_0 + x_1 + x_2 = 0\}$. (Both triples are triangles, since $\det(\mathbf{a}' \mid \mathbf{b}' \mid \mathbf{c}') = 2 \neq 0$.)

Exercise B2: A Pappus configuration.

In $\mathbb{P}^2(\mathbb{Q})$ let $\ell = \{x_1 = 0\}$ and $m = \{x_0 = 0\}$, and take

$$\begin{aligned} A = [1:0:1], \quad B = [1:0:2], \quad C = [1:0:4], \\ A' = [0:1:1], \quad B' = [0:1:3], \quad C' = [0:1:4]. \end{aligned}$$

Compute R, Q, P and the line through them, and verify $\mathbf{p} + \mathbf{r} - \mathbf{q} = \mathbf{0}$.

Solution. With $\mathbf{u} = \mathbf{e}_0$, $\mathbf{w} = \mathbf{e}_1$, $\mathbf{o} = \mathbf{e}_2$ the parameters are $a = 1$, $b = 2$, $c = 4$ and $a' = 1$, $b' = 3$, $c' = 4$. By the formulas in the proof of Theorem 21.9.4,

$$\begin{aligned} \mathbf{r} &= (1-3)\mathbf{e}_0 + (1-2)\mathbf{e}_1 + (1-6)\mathbf{e}_2 = (-2,-1,-5), \\ \mathbf{q} &= (1-4)\mathbf{e}_0 + (1-4)\mathbf{e}_1 + (1-16)\mathbf{e}_2 = (-3,-3,-15), \\ \mathbf{p} &= (3-4)\mathbf{e}_0 + (2-4)\mathbf{e}_1 + (6-16)\mathbf{e}_2 = (-1,-2,-10). \end{aligned}$$

Then $\mathbf{p}+\mathbf{r}=(-3,-3,-15)=\mathbf{q}$, so $\mathbf{p}+\mathbf{r}-\mathbf{q}=\mathbf{0}$. The points are $R=[2:1:5]$, $Q=[1:1:5]$, $P=[1:2:10]$. A linear form vanishing at R and Q is $5x_1-x_2$, and $5\cdot 2-10=0$, so the three lie on $\{5x_1=x_2\}$.

Exercise B3: Concurrency from collinearity.

In $\mathbb{P}^2(\mathbb{Q})$ let $A=[1:0:0]$, $B=[0:1:0]$, $C=[0:0:1]$ and

$$A'=[1:2:2], \qquad B'=[2:1:2], \qquad C'=[2:2:1].$$

Verify the hypotheses of Theorem 21.9.3, then decide whether AA', BB', CC' are concurrent by computing the three points $AB\cap A'B'$, $BC\cap B'C'$, $CA\cap C'A'$ and testing them for collinearity. Do **not** compute the three lines AA', BB', CC'.

Solution. Both triples are triangles: $(\mathbf{e}_0,\mathbf{e}_1,\mathbf{e}_2)$ is a basis, and the determinant of the matrix with rows $(1,2,2)$, $(2,1,2)$, $(2,2,1)$ equals $5\neq 0$. The six vertices are distinct. No vertex of ABC lies on a side of $A'B'C'$, and conversely: the sides of ABC are the three coordinate lines and every primed point has all coordinates non-zero, while $A'B'=\{2x_0+2x_1-3x_2=0\}$, $B'C'=\{-3x_0+2x_1+2x_2=0\}$, $C'A'=\{2x_0-3x_1+2x_2=0\}$, none of which is satisfied by $\mathbf{e}_0$, $\mathbf{e}_1$ or $\mathbf{e}_2$.

Now $AB=\{x_2=0\}$, and a point of $A'B'$ with $x_2=0$ satisfies $2x_0+2x_1=0$, so $AB\cap A'B'=[1:-1:0]$. Cyclically, $BC\cap B'C'=[0:1:-1]$ and $CA\cap C'A'=[-1:0:1]$. The three vectors sum to $\mathbf{0}$, so they are dependent and the points are collinear, on $\{x_0+x_1+x_2=0\}$. By the ($\Leftarrow$) half of Theorem 21.9.3 the three lines AA', BB', CC' are therefore concurrent.

21.9.6.3 C. Going deeper

Exercise C1: Desargues in space.

Let $\dim V=4$, so $\mathbb{P}(V)=\mathbb{P}^3$. Let (A,B,C) and (A',B',C') be triangles spanning **distinct** planes Π and Π' of $\mathbb{P}^3$, with the six vertices distinct, and suppose a point $O\notin\Pi\cup\Pi'$ lies on each of AA', BB', CC'.

(a) Prove that A, B, A', B' lie in one plane of $\mathbb{P}^3$, and deduce that the lines AB and $A'B'$ meet.

(b) Prove that $\Pi\cap\Pi'$ is a line.

(c) Deduce that the three points $AB\cap A'B'$, $BC\cap B'C'$, $CA\cap C'A'$ lie on that line, and so are collinear.

Hint: for (a), all four points lie on lines through O; for (b), use the dimension formula for subspaces.

Solution.

(a) Since $O\notin\Pi\cup\Pi'$ and all six vertices lie in $\Pi\cup\Pi'$, the point O is none of them; and $A\neq A'$, $B\neq B'$ because the six are distinct. Let $\mathbf{o}$ represent O. The points O, A, A' are distinct and collinear, so Lemma 21.9.1 gives representatives with $\mathbf{a}'=\mathbf{a}+\mathbf{o}$, and the same $\mathbf{o}$ gives $\mathbf{b}'=\mathbf{b}+\mathbf{o}$. All four of $\mathbf{a},\mathbf{b},\mathbf{a}',\mathbf{b}'$ then lie in $Z=\operatorname{span}(\mathbf{o},\mathbf{a},\mathbf{b})$,

of dimension at most 3, so the four points lie in the projective subspace $\mathbb{P}(Z)$, of dimension at most 2 — a plane or less. Subtracting, $\mathbf{a}-\mathbf{b}=\mathbf{a}'-\mathbf{b}'$, a vector that is non-zero because $A\neq B$ and that lies in $\operatorname{span}(\mathbf{a},\mathbf{b})\cap\operatorname{span}(\mathbf{a}',\mathbf{b}')$; so $[\mathbf{a}-\mathbf{b}]$ lies on both AB and $A'B'$, and the two lines meet.

(b) $\Pi=\mathbb{P}(S)$ and $\Pi'=\mathbb{P}(S')$ with $\dim S=\dim S'=3$ and $S\neq S'$, inside a 4-dimensional V. Then $S+S'=V$, so by Theorem 1.7.3, $\dim(S\cap S')=3+3-4=2$, and $\mathbb{P}(S\cap S')$ is a line.

(c) First, $AB\neq A'B'$: otherwise A and A' would both lie in Π', hence so would the line AA' and the point O on it, contradicting $O\notin\Pi\cup\Pi'$. Two distinct lines have at most one common point, since two distinct points determine their line (Proposition 21.6.8), and by (a) these two lines do meet; so $AB\cap A'B'$ is a single point. It lies on $AB\subseteq\Pi$ and on $A'B'\subseteq\Pi'$, hence in $\Pi\cap\Pi'$, which is the line of (b). The same holds for the other two points. Three points on one line are collinear.

Exercise C2: Pappus over the two smallest fields.

(a) Prove that the hypotheses of Theorem 21.9.4 cannot be satisfied when $F=\mathbb{F}_2$.

(b) Over $F=\mathbb{F}_3$, take ℓ, m, $\mathbf{o}$, $\mathbf{u}$, $\mathbf{w}$ as in the proof of Theorem 21.9.4 and the parameters $a=a'=0$, $b=b'=1$, $c=c'=2$. Compute $\mathbf{r},\mathbf{q},\mathbf{p}$ and exhibit a line containing all three points.

(c) Explain why the choice of parameters in (b) is the only one available over $\mathbb{F}_3$, up to renaming the points.

Solution.

(a) A line of $\mathbb{P}^2(\mathbb{F}_q)$ is $\mathbb{P}(U)$ with $\dim U=2$, and $U\setminus\{\mathbf{0}\}$ has q^2-1 vectors falling into $(q^2-1)/(q-1)=q+1$ points (Proposition 21.6.9). For $q=2$ a line has 3 points, so $\ell\setminus\{O\}$ has only two, and three distinct points A,B,C of ℓ, none equal to O, do not exist.

(b) With $a=a'=0$, $b=b'=1$, $c=c'=2$ the formulas give

$$\begin{aligned}\mathbf{r}&=(0-1)\mathbf{u}+(0-1)\mathbf{w}+(0-1)\mathbf{o}=(2,2,2),\\ \mathbf{q}&=(0-2)\mathbf{u}+(0-2)\mathbf{w}+(0-4)\mathbf{o}=(1,1,2),\\ \mathbf{p}&=(1-2)\mathbf{u}+(1-2)\mathbf{w}+(1-4)\mathbf{o}=(2,2,0),\end{aligned}$$

all read in $\mathbb{F}_3$ and in the basis $(\mathbf{u},\mathbf{w},\mathbf{o})$. So $R=[1:1:1]$, $Q=[1:1:2]$, $P=[1:1:0]$, and every one of them satisfies $x_0-x_1=0$. That linear form defines a line, and the three points lie on it. As a check, $\mathbf{p}+\mathbf{r}-\mathbf{q}=(2+2-1,\ 2+2-1,\ 0+2-2)=(0,0,0)$ in $\mathbb{F}_3$.

(c) A line of $\mathbb{P}^2(\mathbb{F}_3)$ has $3+1=4$ points, so $\ell\setminus\{O\}$ has exactly three, namely the ones with parameters $0,1,2$; the same on m. The three points A,B,C must therefore be those three in some order, and likewise A',B',C'. Renaming amounts to permuting the parameters, which permutes P, Q, R and changes nothing about their collinearity.

Exercise C3: Why the side hypothesis is there.

In $\mathbb{P}^2(\mathbb{Q})$ let

$$A = [1:0:0], \quad B = [0:1:0], \quad C = [0:0:1],$$
$$A' = [1:1:0], \quad B' = [1:2:0], \quad C' = [1:3:1],$$

and let $O = [1:3:0]$.

(a) Prove that (A, B, C) and (A', B', C') are triangles with six distinct vertices, and that O lies on each of AA', BB', CC'.

(b) Prove that the two triangles are **not** perspective from a line, in the strict sense of Definition 21.9.1.

(c) Say which clause of hypothesis (ii) of Theorem 21.9.3 fails here.

Solution.

(a) $(\mathbf{e}_0, \mathbf{e}_1, \mathbf{e}_2)$ is a basis, so (A, B, C) is a triangle, and

$$\det \begin{pmatrix} 1 & 1 & 0 \\ 1 & 2 & 0 \\ 1 & 3 & 1 \end{pmatrix} = 1 \neq 0,$$

so (A', B', C') is one too. The six coordinate vectors are pairwise non-proportional, so the vertices are distinct. Now A, A', O all have last coordinate 0, hence lie on the line $\{x_2 = 0\}$, and so are collinear; the same for B, B', O. Finally $(1, 3, 1) = (0, 0, 1) + (1, 3, 0)$, so C' lies on the line through C and O.

(b) The line AB is $\{x_2 = 0\}$, since $\mathbf{e}_0$ and $\mathbf{e}_1$ span its underlying plane. The line $A'B'$ is spanned by $(1, 1, 0)$ and $(1, 2, 0)$, an independent pair inside the same plane, so $A'B' = \{x_2 = 0\} = AB$ as well. The pair $\{AB, A'B'\}$ therefore does not consist of distinct lines, and clause (b) of Definition 21.9.1 fails at its first requirement: there is no point "$AB \cap A'B'$" to speak of, the intersection being a whole line.

(c) The clause that no vertex of one triangle lies on a side of the other. Here $A' = [1 : 1 : 0]$ lies on $AB = \{x_2 = 0\}$, and so do B' and O.

21.10 Conics and Lines in Space

Chapter 13 classified symmetric bilinear forms and never drew a picture. This section is the picture. A quadratic form on V has a zero set in $\mathbb{P}(V)$, that zero set is unchanged when the form is scaled, and Sylvester's law becomes a list of shapes. Then a second theme, which looks unrelated and is not: a line in three-dimensional projective space is a plane in F^4, a plane in F^4 is a wedge of two vectors, and the wedges among all of $\Lambda^2 F^4$ are picked out by one quadratic equation. The lines in space are themselves a quadric.

Throughout this section $\operatorname{char} F \neq 2$, except in the Plücker material at the end, which needs no hypothesis on F and says so where it begins. The reason is Chapter 13's: in characteristic 2 a quadratic form is not determined by a symmetric matrix, and every classification theorem we lean on fails.

21.10.1 Quadrics in projective space

A quadratic form q on V is not a function on $\mathbb{P}(V)$: its value at $\lambda\mathbf{x}$ is λ^2 times its value at $\mathbf{x}$, so a point has no well-defined q-value. But whether the value is **zero** does not move, and that is all a zero set needs.

A projective quadric is where a quadratic form vanishes; scaling the vector cannot change whether it does.

Definition 21.10.1 — Projective Quadric, Conic, Smooth Quadric

Let $\operatorname{char} F \neq 2$, let V be a finite-dimensional vector space over F and let q be a **non-zero** quadratic form on V (Definition 13.3.2), with associated symmetric bilinear form β (Theorem 13.3.5). The **projective quadric defined by** q is

$$Z(q) \coloneqq \{\, [\mathbf{x}] \in \mathbb{P}(V) : q(\mathbf{x}) = 0 \,\}.$$

The **rank** of the quadric is $\operatorname{rank}\beta$, and the quadric is **smooth** (or **non-degenerate**) when β is non-degenerate, that is, when the rank is $\dim V$. A quadric in a projective **plane** is called a **conic**, the same word Section 5 used for the affine case (Definition 21.5.1).

The set is well defined: if $\mathbf{x}' = \lambda\mathbf{x}$ with $\lambda \neq 0$, then $q(\mathbf{x}') = \beta(\lambda\mathbf{x}, \lambda\mathbf{x}) = \lambda^2 q(\mathbf{x})$, which is zero exactly when $q(\mathbf{x})$ is. The word **non-zero** in the definition rules out $q = 0$, whose zero set is all of $\mathbb{P}(V)$ and carries no information. And the rank is well defined because β is: over a field of characteristic $\neq 2$ a quadratic form has exactly one symmetric bilinear form behind it (Theorem 13.3.5).

Fix a basis of V. Then $q(\mathbf{x}) = \mathbf{x}^{\top}\mathbf{A}\mathbf{x}$ for a unique symmetric matrix $\mathbf{A}$, the matrix of β (Definition 13.1.2), and $\operatorname{rank}\mathbf{A}$ is the rank of the quadric. Three examples in $\mathbb{P}^2$, written in homogeneous coordinates $[x_0 : x_1 : x_2]$.

- $q = x_0^2 + x_1^2 - x_2^2$, with $\mathbf{A} = \operatorname{diag}(1, 1, -1)$, rank 3, smooth. Over $\mathbb{R}$ its points are the projective version of the unit circle; $[1 : 0 : 1]$ is one of them.
- $q = x_0 x_1$, with $\mathbf{A} = \begin{pmatrix} 0 & 1/2 & 0 \\ 1/2 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$, rank 2. Its zero set is the union of the two lines $\{x_0 = 0\}$ and $\{x_1 = 0\}$.
- $q = x_0^2$, rank 1. Its zero set is the single line $\{x_0 = 0\}$, because a field has no non-zero element whose square is 0. The form remembers something the set forgets, which is the first warning of the section.

Warning. **A quadric is named by its form, not by its set.** Over $\mathbb{R}$ the distinct forms $x_0^2 + x_1^2 + x_2^2$ and $2x_0^2 + 5x_1^2 + x_2^2$ have the same zero set in $\mathbb{P}^2(\mathbb{R})$, namely the empty set, which records nothing at all about either of them. So "the quadric $Z(q)$" is always shorthand for "the quadric defined by q", and the theorem below classifies **forms** up to projective equivalence, not sets.

A projective transformation $[\mathbf{x}] \mapsto [T\mathbf{x}]$ (Definition 21.7.1) carries $Z(q)$ to $Z(q \circ T^{-1})$, and $Z(q) = Z(cq)$ for every $c \neq 0$. So the right relation on forms is: q and q' are **projectively equivalent** when $q' = c\,(q \circ T)$ for some $c \in F^{\times}$ and some $T \in \mathrm{GL}(V)$. In matrices: $\mathbf{A}' = c\,\mathbf{P}^{\top}\mathbf{A}\mathbf{P}$ with $\mathbf{P}$ invertible, which is congruence (Definition 13.2.1) followed by a scaling.

Theorem 21.10.1 — Classification of Projective Quadrics

Let $\operatorname{char} F \neq 2$ and $\dim V = n+1$, and let q, q' be non-zero quadratic forms on V with matrices $\mathbf{A}, \mathbf{A}'$ in some basis.

(a) If F is algebraically closed, then q and q' are projectively equivalent if and only if $\operatorname{rank}\mathbf{A} = \operatorname{rank}\mathbf{A}'$. There are exactly $n+1$ classes, one for each rank $r = 1, \dots, n+1$, with normal form $x_0^2 + \cdots + x_{r-1}^2$.

(b) If $F = \mathbb{R}$, then q and q' are projectively equivalent if and only if their inertias (n_+, n_-, n_0) and (n'_+, n'_-, n'_0) agree **up to interchanging** n_+ **with** n_-. A normal form is $x_0^2 + \cdots + x_{n_+-1}^2 - x_{n_+}^2 - \cdots - x_{r-1}^2$ with $n_+ \geq n_-$, $r = n_+ + n_-$.

Idea. Both parts reduce the extra freedom — the scalar c — to something already classified. Over an algebraically closed field c has a square root, so scaling is itself a congruence and adds nothing: the answer is Chapter 13's. Over $\mathbb{R}$ a positive c is again a congruence, and the only new move is $c = -1$, which turns q into $-q$ and swaps the two counts.

Proof.

(a) ($\Leftarrow$) It is enough to show that a symmetric $\mathbf{A}$ of rank $r \geq 1$ is congruent to $\mathbf{I}_r \oplus \mathbf{0}$, since a congruence is the case $c = 1$ and congruence is an equivalence relation (Proposition 13.2.2). By Theorem 13.4.2, $\mathbf{A} \simeq \mathbf{D} = \operatorname{diag}(d_1, \dots, d_{n+1})$, and congruence preserves rank (Theorem 13.2.3), so exactly r of the d_i are non-zero; permuting the basis, a congruence by a permutation matrix, we may assume these are $d_1, \dots, d_r$. Since F is algebraically closed, choose s_i with $s_i^2 = d_i$ for $i \leq r$ and put $t_i = 1/s_i$ for $i \leq r$, $t_i = 1$ otherwise; by Proposition 13.4.3 the congruence by $\operatorname{diag}(t_1, \dots, t_{n+1})$ replaces d_i by $t_i^2 d_i$, giving $\mathbf{I}_r \oplus \mathbf{0}$. (For $F = \mathbb{C}$ this is Corollary 13.4.4.)
($\Rightarrow$) Suppose $\mathbf{A}' = c\,\mathbf{P}^{\top}\mathbf{A}\mathbf{P}$ with $c \neq 0$. Choose $s \in F$ with $s^2 = c$; then $\mathbf{A}' = (s\mathbf{P})^{\top}\mathbf{A}(s\mathbf{P})$ with $s\mathbf{P}$ invertible, so $\mathbf{A}' \simeq \mathbf{A}$ and Theorem 13.2.3 gives $\operatorname{rank}\mathbf{A}' = \operatorname{rank}\mathbf{A}$. The ranks of a non-zero form run over $1, \dots, n+1$, and the normal form is the $\mathbf{I}_r \oplus \mathbf{0}$ produced above, whose quadratic form is $x_0^2 + \cdots + x_{r-1}^2$.

(b) ($\Leftarrow$) If the inertias agree, Corollary 13.5.2 (b) gives $\mathbf{A}' \simeq \mathbf{A}$, which is the case $c = 1$. If they agree after interchanging n_+ and n_-, then $\mathbf{A}'$ has the same inertia as $-\mathbf{A}$, so $\mathbf{A}' \simeq -\mathbf{A} = (-1)\mathbf{A}$, which is the case $c = -1$ composed with a congruence.

($\Rightarrow$) Let $\mathbf{A}' = c\,\mathbf{P}^{\top}\mathbf{A}\mathbf{P}$. If $c > 0$, put $s = \sqrt{c}$ and argue as in (a): $\mathbf{A}' \simeq \mathbf{A}$, so the inertias agree by Corollary 13.5.2 (b). If $c < 0$, put $s = \sqrt{-c}$; then $\mathbf{A}' = (s\mathbf{P})^{\top}(-\mathbf{A})(s\mathbf{P}) \simeq -\mathbf{A}$. Diagonalizing $\mathbf{A}$ with n_+ positive and n_- negative entries diagonalizes $-\mathbf{A}$ with the two counts interchanged, so the inertia of $-\mathbf{A}$, hence of $\mathbf{A}'$, is (n_-, n_+, n_0) by Theorem 13.5.1. This proves the theorem.

■

For $n = 2$ the list is short enough to write out, and worth memorizing.

Corollary 21.10.2 — The Conics of a Projective Plane

Let $\operatorname{char} F \neq 2$ and let q be a non-zero quadratic form on a 3-dimensional space.

(a) Over an algebraically closed F there are three classes, with zero sets: a line (rank 1), two distinct lines (rank 2), a smooth conic (rank 3).

(b) Over $\mathbb{R}$ there are five classes, listed by (n_+, n_-) with $n_+ \geq n_-$, with zero sets:

$(1,0)$: a line, $(2,0)$: a single point,
$(1,1)$: two distinct lines, $(3,0)$: empty,
$(2,1)$: a smooth conic, non-empty.

Proof. The classes are those of Theorem 21.10.1; only the zero sets need identifying, and each is read off a normal form.

$x_0^2 = 0$ holds exactly when $x_0 = 0$, a field having no non-zero square root of 0; the set is the line $\{x_0 = 0\}$. Next, $x_0^2 + x_1^2$ factors over an algebraically closed field as $(x_0 + ix_1)(x_0 - ix_1)$ with $i^2 = -1$, and the two linear forms are not proportional since $i \neq -i$ (as $\operatorname{char} F \neq 2$), so the set is two distinct lines; over $\mathbb{R}$ instead $x_0^2 + x_1^2 = 0$ forces $x_0 = x_1 = 0$, leaving the single point $[0:0:1]$. The form $x_0^2 - x_1^2 = (x_0 - x_1)(x_0 + x_1)$ gives two distinct lines over every field of characteristic $\neq 2$. Over $\mathbb{R}$, $x_0^2 + x_1^2 + x_2^2 = 0$ forces $\mathbf{x} = \mathbf{0}$, which is not a point of $\mathbb{P}^2$, so the set is empty. Finally $x_0^2 + x_1^2 - x_2^2$ has rank 3, so its quadric is smooth, and it contains $[1:0:1]$. This proves the corollary. ∎

Remark. Section 5 classified **affine** quadrics and produced a longer real list, because an affine classification must also record whether a center exists and whether the constant can be cleared. There is no conflict: the affine group is smaller than the projective one — an invertible affine substitution is exactly a projectivity fixing the hyperplane at infinity (Theorem 21.7.11) — so the affine classification is the finer of the two, and the list above is what Section 5 pointed forward to for the complex case.

Warning. **Rank alone does not classify real conics; inertia does.** The forms $x_0^2 + x_1^2 + x_2^2$ and $x_0^2 + x_1^2 - x_2^2$ both have rank 3, and one zero set is empty while the other has infinitely many points. One rank lower, $x_0^2 + x_1^2$ and $x_0^2 - x_1^2$ both have rank 2, and the zero sets are a point and a pair of lines. Over $\mathbb{C}$ each pair collapses: rank is a complete invariant there, so the two forms of each pair become projectively equivalent.

Example. (Classifying a conic by hand)

Classify the conic $x_0^2 + 4x_0x_1 + 5x_1^2 + 2x_1x_2 + 2x_2^2 = 0$ in $\mathbb{P}^2(\mathbb{R})$, and say what happens over $\mathbb{C}$.

Solution. Complete the square in x_0 first, since x_0^2 appears:

$$x_0^2 + 4x_0x_1 = (x_0 + 2x_1)^2 - 4x_1^2,$$

so the form equals $(x_0 + 2x_1)^2 + x_1^2 + 2x_1x_2 + 2x_2^2$. Completing the square in x_1 in what is left, $x_1^2 + 2x_1x_2 = (x_1 + x_2)^2 - x_2^2$, and therefore

$$q = (x_0 + 2x_1)^2 + (x_1 + x_2)^2 + x_2^2.$$

The three linear forms $x_0 + 2x_1$, $x_1 + x_2$, x_2 are independent — the matrix with these rows is upper triangular with determinant 1 — so this is a diagonalization with inertia $(3, 0, 0)$. By Corollary 21.10.2 (b) the conic is **empty** over $\mathbb{R}$.

Over $\mathbb{C}$ the same three squares have rank 3, so by (a) the conic is smooth, and it is not empty: take $x_2 = 1$ and $x_1 = -1$, so that the second square vanishes and the equation becomes $(x_0 - 2)^2 = -1$, solved by $x_0 = 2 + i$. The point $[2 + i : -1 : 1]$ lies on it. The real conic was empty not because the form was degenerate but because it was definite, which is a statement no algebraically closed field can make.

Quick check. A conic in $\mathbb{P}^2(\mathbb{R})$ consists of exactly one point. What is the rank of its form, and what is its inertia?

Solution. By the list in Corollary 21.10.2 (b) the only class with a one-point zero set is $(n_+, n_-) = (2, 0)$, of rank 2; up to sign the form is $x_0^2 + x_1^2$ in suitable coordinates. Rank 1 gives a line and rank 3 gives either nothing or a curve, so no other class can produce one point.

21.10.2 Five points determine a conic

Six coefficients, five conditions, one answer. The existence half is a count; the uniqueness half is where the work is, and it is exactly where "in general position" earns its keep.

"In general position" is Definition 21.7.2 read with $m = 5$ and $n = 2$: every subset of at most three of the five points has independent representatives. In a projective plane that says exactly that the five points are pairwise distinct and that no three of them are collinear.

The lemma below is what forbids a conic from swallowing a line, and it is used twice more later.

Lemma 21.10.3 — A Conic Containing a Line Is Degenerate

Let $\operatorname{char} F \neq 2$, let $\dim V = 3$ and let $q \neq 0$ be a quadratic form on V vanishing on every vector of a 2-dimensional subspace W. Then $q = \varphi\chi$ for two non-zero linear functionals φ, χ on V with $\ker \varphi = W$, and the rank of q is at most 2. In particular a **smooth** conic contains no line.

Proof. Let β be the symmetric form of q and choose a basis $(\mathbf{w}_0, \mathbf{w}_1, \mathbf{v}_2)$ of V with $W = \operatorname{span}(\mathbf{w}_0, \mathbf{w}_1)$. Evaluating q at $\mathbf{w}_0$, at $\mathbf{w}_1$ and at $\mathbf{w}_0 + \mathbf{w}_1$, all of which lie in W, gives

$$\beta(\mathbf{w}_0, \mathbf{w}_0) = 0, \quad \beta(\mathbf{w}_1, \mathbf{w}_1) = 0, \quad 2\beta(\mathbf{w}_0, \mathbf{w}_1) = 0,$$

the third because $q(\mathbf{w}_0+\mathbf{w}_1) = \beta(\mathbf{w}_0, \mathbf{w}_0)+2\beta(\mathbf{w}_0, \mathbf{w}_1)+\beta(\mathbf{w}_1, \mathbf{w}_1)$. Since 2 is invertible, $\beta(\mathbf{w}_0, \mathbf{w}_1) = 0$ too. Put $c_0 = \beta(\mathbf{w}_0, \mathbf{v}_2)$, $c_1 = \beta(\mathbf{w}_1, \mathbf{v}_2)$ and $c = \beta(\mathbf{v}_2, \mathbf{v}_2)$. In the coordinates $\mathbf{x} = (x_0, x_1, x_2)$ of this basis,

$$q(\mathbf{x}) = 2c_0x_0x_2 + 2c_1x_1x_2 + cx_2^2 = x_2\big(2c_0x_0 + 2c_1x_1 + cx_2\big),$$

a product $\varphi\chi$ with $\varphi(\mathbf{x}) = x_2$, whose kernel is W, and χ the second factor, which is non-zero because $q \neq 0$. The Gram matrix of β in this basis (Definition 13.1.2) has rows

$(0,0,c_0)$, $(0,0,c_1)$ and (c_0,c_1,c); the first two lie in a 1-dimensional subspace, so the three of them span at most a 2-dimensional one and the rank is at most 2.

If q is smooth its rank is 3, so no such W exists, and a line $\mathbb{P}(W)$ contained in $Z(q)$ would supply one. This proves the lemma.

■

Theorem 21.10.4 — Five Points Determine a Conic

Let $\operatorname{char} F \neq 2$ and let $P_1,\dots,P_5$ be five points of $\mathbb{P}^2$ in general position (Definition 21.7.2), that is, pairwise distinct with no three collinear. Then there is a non-zero quadratic form q on F^3 vanishing at all five, and it is unique up to a non-zero scalar. Consequently exactly one conic passes through the five points.

Idea. The symmetric 3×3 matrices form a 6-dimensional space and each point imposes one linear equation on it, so five points leave at least a line of solutions: that is existence, and it is only counting. For uniqueness suppose the solution space had dimension 2. Then a whole pencil of conics passes through the five points, and a pencil is big enough to be forced through a **sixth** point, chosen on the line P_1P_2. A conic through three points of a line contains the line, so by Lemma 21.10.3 it splits into two lines; one of them is P_1P_2, and the other must then carry P_3,P_4,P_5 — three collinear points, which general position forbids.

Proof. Let $S\subseteq M_3(F)$ be the subspace of symmetric matrices. A symmetric 3×3 matrix is determined by its three diagonal entries and its three entries above the diagonal, each of which may be chosen freely, so $\dim S = 6$. By Theorem 13.3.5 the map $\mathbf{A}\mapsto q_{\mathbf{A}}$, $q_{\mathbf{A}}(\mathbf{x}) = \mathbf{x}^{\top}\mathbf{A}\mathbf{x}$, is a bijection from S onto the quadratic forms on F^3, and it is linear.

Existence. Write $P_i = [\mathbf{x}_i]$. For each i the map $\mathbf{A}\mapsto \mathbf{x}_i^{\top}\mathbf{A}\mathbf{x}_i$ is a linear functional on S, because the expression is linear in the entries of $\mathbf{A}$. The five functionals give a homogeneous linear system of 5 equations in the 6 coordinates of $\mathbf{A}$, which by Corollary 2.2.5 (a) has a non-trivial solution $\mathbf{A}\neq\mathbf{0}$. The corresponding $q_{\mathbf{A}}$ is a non-zero quadratic form vanishing at every $\mathbf{x}_i$, hence at every P_i. (Vanishing does not depend on the representative, by the homogeneity noted after Definition 21.10.1.)

Uniqueness. Let $N\subseteq S$ be the solution space of that system, and suppose $\dim N\geq 2$. Pick independent $\mathbf{A}_1,\mathbf{A}_2\in N$, and write q_1,q_2 for the corresponding forms, which are independent as forms since $\mathbf{A}\mapsto q_{\mathbf{A}}$ is a bijection that is linear.

The line $L = P_1P_2$ contains at least three points: it is $\mathbb{P}(U)$ with $\dim U = 2$, so it contains $[\mathbf{u}_1]$, $[\mathbf{u}_2]$ and $[\mathbf{u}_1+\mathbf{u}_2]$ for a basis $(\mathbf{u}_1,\mathbf{u}_2)$ of U, and these are three distinct points. Choose $R=[\mathbf{y}]$ on L with $R\neq P_1$ and $R\neq P_2$. The condition $\lambda\,\mathbf{y}^{\top}\mathbf{A}_1\mathbf{y}+\mu\,\mathbf{y}^{\top}\mathbf{A}_2\mathbf{y}=0$ is one homogeneous linear equation in (λ,μ), so by Corollary 2.2.5 (a) it has a solution with $(\lambda,\mu)\neq(0,0)$. Put $\mathbf{A}=\lambda\mathbf{A}_1+\mu\mathbf{A}_2$, which is non-zero because $\mathbf{A}_1,\mathbf{A}_2$ are independent, and let $q=q_{\mathbf{A}}$, a non-zero quadratic form.

Now q vanishes at the three distinct points P_1,P_2,R of L. Restrict q to U: in the basis $(\mathbf{u}_1,\mathbf{u}_2)$ it reads $g(s,t)=\alpha s^2+\gamma st+\delta t^2$. A non-zero g vanishes at at most two points of $\mathbb{P}(U)$. Indeed, if $\alpha\neq 0$ then $g(s,0)=\alpha s^2\neq 0$ whenever $s\neq 0$, so every zero has $t\neq 0$ and is therefore $[m:1]$ for a scalar m with $\alpha m^2+\gamma m+\delta=0$ — a polynomial in m of degree at most 2, non-zero because its leading coefficient is α, so with at most two roots

(Lemma 2.7.2); if $\alpha = 0$ then $g = t(\gamma s + \delta t)$, whose zeros are $[1:0]$ together with the at most one point where $\gamma s + \delta t = 0$, and $(\gamma, \delta) \neq (0,0)$ since $g \neq 0$. Three zeros therefore force $g = 0$, that is, q vanishes on all of U.

By Lemma 21.10.3, $q = \varphi\chi$ with $\ker\varphi = U$. For $i = 3,4,5$ we have $q(\mathbf{x}_i) = 0$, and $\varphi(\mathbf{x}_i) \neq 0$, since $\varphi(\mathbf{x}_i) = 0$ would put P_i on $L = P_1P_2$, making P_1, P_2, P_i collinear. Hence $\chi(\mathbf{x}_i) = 0$ for $i = 3,4,5$, so P_3, P_4, P_5 all lie on the line $\{\chi = 0\}$ — three collinear points among the five, contradicting general position.

So $\dim N = 1$: the form is unique up to a non-zero scalar, and $Z(q)$ is the unique conic through the five points. This proves the theorem.

■

Example. (A conic through five points)

Find the conic of $\mathbb{P}^2(\mathbb{Q})$ through $[1:0:0]$, $[0:1:0]$, $[0:0:1]$, $[1:1:1]$ and $[1:2:4]$, and decide whether it is smooth.

Solution. Write $q = ax_0^2 + bx_1^2 + cx_2^2 + dx_0x_1 + ex_0x_2 + fx_1x_2$. The first three points give $a = b = c = 0$ at once. Then $[1:1:1]$ gives $d + e + f = 0$ and $[1:2:4]$ gives $2d + 4e + 8f = 0$, that is $d + 2e + 4f = 0$. Subtracting, $e + 3f = 0$, so $e = -3f$ and $d = -e - f = 2f$. Taking $f = 1$,

$$q = 2x_0x_1 - 3x_0x_2 + x_1x_2,$$

and the solution space is indeed one-dimensional, as Theorem 21.10.4 promises. (No three of the five points are collinear: taking the ten triples in the order 123, 124, 125, 134, 135, 145, 234, 235, 245, 345, the determinants of the corresponding coordinate matrices are

$$1,\ 1,\ 4,\ -1,\ -2,\ 2,\ 1,\ 1,\ -3,\ 1,$$

none of them zero.)

Its matrix is

$$\mathbf{A} = \begin{pmatrix} 0 & 1 & -3/2 \\ 1 & 0 & 1/2 \\ -3/2 & 1/2 & 0 \end{pmatrix}, \qquad \det\mathbf{A} = -\tfrac{3}{2} \neq 0,$$

so the conic is smooth. Over $\mathbb{R}$ its inertia is $(2,1,0)$: the three eigenvalues are real (Corollary 11.5.2) and the inertia counts their signs (Theorem 13.5.3); their product is $\det\mathbf{A} < 0$, so an odd number of them is negative, and $\operatorname{tr}\mathbf{A} = 0$ rules out all three, leaving exactly one.

21.10.3 Projecting a conic onto a line

Here is the payoff a reader can take home. A smooth conic looks like a curve, and the next theorem says that as a set it **is** a projective line, provided it has one point to start from. Over $\mathbb{Q}$ that converts one solution of a Diophantine equation into all of them; over $\mathbb{F}_q$ it says a smooth conic with a point has exactly $q + 1$ of them.

Theorem 21.10.5 — Projection from a Point of a Conic

Let $\operatorname{char} F \neq 2$, let $C = Z(q)$ be a **smooth** conic in $\mathbb{P}(V)$, $\dim V = 3$, and suppose C contains a point $P_0 = [\mathbf{p}]$. Let ℓ be any line of $\mathbb{P}(V)$ with $P_0 \notin \ell$. Then the map

$$\psi\colon \ell \to C, \qquad \psi([\mathbf{x}]) = \big[\, -q(\mathbf{x})\,\mathbf{p} + 2\beta(\mathbf{p},\mathbf{x})\,\mathbf{x}\,\big]$$

is a well-defined bijection. In particular C is in bijection with $\mathbb{P}^1$.

Idea. Each point X of ℓ is joined to P_0, and the line P_0X meets C in P_0 and in exactly one further point — "further" understood so that a tangent line counts P_0 twice. Expanding $q(\lambda\mathbf{p}+\mu\mathbf{x})$ and using $q(\mathbf{p}) = 0$ makes μ a factor, so the quadratic equation is linear once the known root is removed, and the displayed formula is that root written out. Every line through P_0 other than ℓ itself meets ℓ once, which is where the inverse comes from.

Proof. Write $\ell = \mathbb{P}(U)$ with $\dim U = 2$; since $P_0 \notin \ell$, we have $\mathbf{p} \notin U$, so $\mathbf{x} \notin \operatorname{span}(\mathbf{p})$ for every $\mathbf{0} \neq \mathbf{x} \in U$.

The formula is well defined. Replacing $\mathbf{x}$ by $c\mathbf{x}$ with $c \neq 0$ multiplies $-q(\mathbf{x})\mathbf{p}+2\beta(\mathbf{p},\mathbf{x})\mathbf{x}$ by c^2, so the point is unchanged. The vector is non-zero: if both $q(\mathbf{x}) = 0$ and $\beta(\mathbf{p},\mathbf{x}) = 0$, then for all λ, μ,

$$q(\lambda\mathbf{p} + \mu\mathbf{x}) = \lambda^2 q(\mathbf{p}) + 2\lambda\mu\,\beta(\mathbf{p},\mathbf{x}) + \mu^2 q(\mathbf{x}) = 0,$$

so q vanishes on the 2-dimensional subspace $\operatorname{span}(\mathbf{p},\mathbf{x})$, contradicting Lemma 21.10.3 since C is smooth. If instead $\beta(\mathbf{p},\mathbf{x}) \neq 0$ the vector has a non-zero component along $\mathbf{x}$ modulo $\operatorname{span}(\mathbf{p})$; and if $\beta(\mathbf{p},\mathbf{x}) = 0$ with $q(\mathbf{x}) \neq 0$, the vector is $-q(\mathbf{x})\mathbf{p} \neq \mathbf{0}$.

The value lies on C. Put $\mathbf{z} = -q(\mathbf{x})\mathbf{p} + 2\beta(\mathbf{p},\mathbf{x})\mathbf{x}$. Using $q(\mathbf{p}) = 0$ and bilinearity,

$$\begin{aligned} q(\mathbf{z}) &= q(\mathbf{x})^2 q(\mathbf{p}) - 2\cdot 2q(\mathbf{x})\beta(\mathbf{p},\mathbf{x})\,\beta(\mathbf{p},\mathbf{x}) + 4\beta(\mathbf{p},\mathbf{x})^2 q(\mathbf{x}) \\ &= 0 - 4q(\mathbf{x})\beta(\mathbf{p},\mathbf{x})^2 + 4\beta(\mathbf{p},\mathbf{x})^2 q(\mathbf{x}) = 0. \end{aligned}$$

A fact used twice. If $[\mathbf{y}] \in C$ and $[\mathbf{y}] \neq P_0$, then $\beta(\mathbf{p},\mathbf{y}) \neq 0$; otherwise q would vanish on $\operatorname{span}(\mathbf{p},\mathbf{y})$, a 2-dimensional subspace since $\mathbf{p},\mathbf{y}$ represent distinct points, contradicting Lemma 21.10.3 again.

Surjectivity. Let $[\mathbf{y}] \in C$. Suppose first $[\mathbf{y}] \neq P_0$. The line $P_0[\mathbf{y}]$ is distinct from ℓ, since $P_0 \notin \ell$, so by Corollary 21.6.7 it meets ℓ in a single point $[\mathbf{x}]$, and $\mathbf{x} = \lambda\mathbf{p} + \mu\mathbf{y}$ with $\mu \neq 0$ (else $[\mathbf{x}] = P_0 \in \ell$). Then $q(\mathbf{x}) = 2\lambda\mu\,\beta(\mathbf{p},\mathbf{y})$ and $\beta(\mathbf{p},\mathbf{x}) = \mu\,\beta(\mathbf{p},\mathbf{y})$, so

$$\begin{aligned} -q(\mathbf{x})\mathbf{p} + 2\beta(\mathbf{p},\mathbf{x})\mathbf{x} &= -2\lambda\mu\beta(\mathbf{p},\mathbf{y})\,\mathbf{p} + 2\mu\beta(\mathbf{p},\mathbf{y})(\lambda\mathbf{p} + \mu\mathbf{y}) \\ &= 2\mu^2\beta(\mathbf{p},\mathbf{y})\,\mathbf{y}, \end{aligned}$$

which is a non-zero multiple of $\mathbf{y}$ by the fact just proved. So $\psi([\mathbf{x}]) = [\mathbf{y}]$. Now suppose $[\mathbf{y}] = P_0$. The set $T = \{[\mathbf{z}] : \beta(\mathbf{p},\mathbf{z}) = 0\}$ is a line, β being non-degenerate so that $\beta(\mathbf{p},\cdot)$ is a non-zero functional; it contains P_0, because $\beta(\mathbf{p},\mathbf{p}) = q(\mathbf{p}) = 0$, hence $T \neq \ell$, and T meets ℓ in one point $[\mathbf{x}]$. There $\beta(\mathbf{p},\mathbf{x}) = 0$ and $q(\mathbf{x}) \neq 0$ by the non-vanishing argument above, so $\psi([\mathbf{x}]) = [-q(\mathbf{x})\mathbf{p}] = P_0$.

Injectivity. Suppose $\psi([\mathbf{x}']) = \psi([\mathbf{x}'']) = [\mathbf{y}]$, with $[\mathbf{x}'], [\mathbf{x}''] \in \ell$. For any $\mathbf{x}$ the vector $-q(\mathbf{x})\mathbf{p}+2\beta(\mathbf{p},\mathbf{x})\mathbf{x}$ lies in $\operatorname{span}(\mathbf{p},\mathbf{x})$, so $[\mathbf{y}]$ lies on the line joining P_0 to $[\mathbf{x}]$. If $[\mathbf{y}] \neq P_0$,

then both $[\mathbf{x}']$ and $[\mathbf{x}'']$ lie on the line joining P_0 to $[\mathbf{y}]$, and both lie on ℓ; these two lines are distinct because $P_0 \notin \ell$, so by Corollary 21.6.7 they meet in one point and $[\mathbf{x}'] = [\mathbf{x}'']$. If $[\mathbf{y}] = P_0$, then $2\beta(\mathbf{p}, \mathbf{x}')\mathbf{x}' \in \operatorname{span}(\mathbf{p})$; since $\mathbf{x}' \notin \operatorname{span}(\mathbf{p})$ and 2 is invertible, $\beta(\mathbf{p}, \mathbf{x}') = 0$, and likewise for $\mathbf{x}''$. So $[\mathbf{x}']$ and $[\mathbf{x}'']$ both lie on $T \cap \ell$, again a single point.

Finally ℓ is a projective line, hence in bijection with $\mathbb{P}^1$ by any choice of basis of U. This proves the theorem.

■

Example. (Pythagorean triples from one point)

Parametrize the rational points of the conic $x_0^2 + x_1^2 = x_2^2$ in $\mathbb{P}^2(\mathbb{Q})$, starting from $P_0 = [-1 : 0 : 1]$.

Solution. Here $q(\mathbf{x}) = x_0^2 + x_1^2 - x_2^2$, with $\beta(\mathbf{x}, \mathbf{y}) = x_0y_0 + x_1y_1 - x_2y_2$, and $\mathbf{A} = \operatorname{diag}(1, 1, -1)$ is invertible, so the conic is smooth. Also $q(-1, 0, 1) = 1 - 1 = 0$, so $P_0 \in C$. Take $\ell = \{x_0 = 0\}$, which misses P_0, and write its points as $[0 : u : v]$ with $(u, v) \neq (0, 0)$.

With $\mathbf{x} = (0, u, v)$ we get $q(\mathbf{x}) = u^2 - v^2$ and $\beta(\mathbf{p}, \mathbf{x}) = -v$, so

$$\begin{aligned} \psi([0 : u : v]) &= \big[-(u^2 - v^2)(-1, 0, 1) + 2(-v)(0, u, v)\big] \\ &= \big[\, u^2 - v^2 \;:\; -2uv \;:\; -u^2 - v^2 \,\big] \\ &= \big[\, v^2 - u^2 \;:\; 2uv \;:\; u^2 + v^2 \,\big]. \end{aligned}$$

Taking u, v to be integers, not both zero, the three coordinates are integers, and

$$(v^2 - u^2)^2 + (2uv)^2 = u^4 + 2u^2v^2 + v^4 = (u^2 + v^2)^2,$$

a Pythagorean triple; the identity is exactly the statement that ψ lands in C.

By Theorem 21.10.5 every point of C arises from exactly one point $[0 : u : v]$ of ℓ. So if (a, b, c) are integers with $a^2 + b^2 = c^2$ and $c \neq 0$, then $[a : b : c]$ is a rational point of C, hence

$$(a, b, c) = \lambda\,(v^2 - u^2,\; 2uv,\; u^2 + v^2)$$

for some rational $\lambda \neq 0$ and integers u, v: every Pythagorean triple is proportional to one of this shape. (If $c = 0$ then $a^2 + b^2 = 0$ forces $a = b = 0$.) Deciding **which** proportionality factors give primitive triples is arithmetic about parities and common factors, not linear algebra, and we do not do it here.

Two checks. At $[u : v] = [1 : 0]$, that is at the point $[0 : 1 : 0]$ of ℓ, the formula returns $[-1 : 0 : 1] = P_0$. That is as it should be: the line joining P_0 to $[0 : 1 : 0]$ consists of the points $[-\lambda : \mu : \lambda]$, and $q(-\lambda, \mu, \lambda) = \lambda^2 + \mu^2 - \lambda^2 = \mu^2$, which vanishes only for $\mu = 0$. So that line meets C at P_0 alone, and P_0 is the only value ψ can take there. At $[u : v] = [1 : 2]$ the formula gives $[3 : 4 : 5]$.

21.10.4 Pole, polar and the dual conic

A smooth conic carries an invertible symmetric matrix, and an invertible symmetric matrix is a perfect pairing. Every point therefore names a line, and the dictionary this sets up is where tangency comes from.

Definition 21.10.2 — Polar Line, Tangent Line

Let $C = Z(q)$ be a smooth conic in $\mathbb{P}(V)$, $\dim V = 3$, with symmetric bilinear form β, and let $P = [\mathbf{x}]$. The **polar** of P with respect to C is

$$P^{\beta} := \{\, [\mathbf{y}] \in \mathbb{P}(V) : \beta(\mathbf{x}, \mathbf{y}) = 0 \,\},$$

and P is the **pole** of that line. For $P \in C$, the polar P^{β} is called the **tangent line** to C at P.

Because β is non-degenerate, $\beta(\mathbf{x}, \cdot)$ is a non-zero functional (Proposition 13.1.2 (c)), so its kernel is 2-dimensional and P^{β} really is a line; and replacing $\mathbf{x}$ by $c\mathbf{x}$ scales the functional, leaving the line alone. The next proposition says the word "tangent" is deserved.

Proposition 21.10.6 — Reciprocity and Tangency

With the notation of Definition 21.10.2, let $P = [\mathbf{x}]$ and $Q = [\mathbf{y}]$.

(a) $Q \in P^{\beta}$ if and only if $P \in Q^{\beta}$.

(b) $P \in C$ if and only if $P \in P^{\beta}$.

(c) Let $P \in C$ and let L be a line through P. Then $L \cap C = \{P\}$ if and only if $L = P^{\beta}$; every other line through P meets C in exactly two points.

Proof.

(a) Both conditions say $\beta(\mathbf{x}, \mathbf{y}) = 0$, since β is symmetric.

(b) $P \in P^{\beta}$ says $\beta(\mathbf{x}, \mathbf{x}) = 0$, which is $q(\mathbf{x}) = 0$.

(c) Write $L = \mathbb{P}(\operatorname{span}(\mathbf{x}, \mathbf{y}))$ with $\mathbf{y} \notin \operatorname{span}(\mathbf{x})$. A point of L is $[\lambda\mathbf{x} + \mu\mathbf{y}]$, and since $q(\mathbf{x}) = 0$,

$$q(\lambda\mathbf{x} + \mu\mathbf{y}) = \mu\big(2\lambda\,\beta(\mathbf{x}, \mathbf{y}) + \mu\, q(\mathbf{y})\big).$$

Case 1: $L = P^{\beta}$, that is, $\beta(\mathbf{x}, \mathbf{y}) = 0$. Then $q(\lambda\mathbf{x} + \mu\mathbf{y}) = \mu^2 q(\mathbf{y})$, and $q(\mathbf{y}) \neq 0$: otherwise q would vanish on $\operatorname{span}(\mathbf{x}, \mathbf{y})$, contradicting Lemma 21.10.3. So the expression vanishes only when $\mu = 0$, giving the single point P.

Case 2: $L \neq P^{\beta}$, so $\beta(\mathbf{x}, \mathbf{y}) \neq 0$. Then the factorization above vanishes when $\mu = 0$, giving P, and when $2\lambda\beta(\mathbf{x}, \mathbf{y}) + \mu q(\mathbf{y}) = 0$, which has the solution $(\lambda, \mu) = (-q(\mathbf{y}),\ 2\beta(\mathbf{x}, \mathbf{y}))$ with $\mu \neq 0$, giving a point of C different from P. Every point of $L \cap C$ is one of these two, since the two cases $\mu = 0$ and $2\lambda\beta(\mathbf{x}, \mathbf{y}) + \mu q(\mathbf{y}) = 0$ exhaust the factorization and each determines $[\lambda : \mu]$. This proves the proposition.

■

Corollary 21.10.7 — The Dual Conic

Let C be a smooth conic in $\mathbb{P}(V)$ with matrix $\mathbf{A}$ in some basis, and identify each line of $\mathbb{P}(V)$ with the point $[\varphi]$ of $\mathbb{P}(V^*)$ for which the line is $\mathbb{P}(\ker\varphi)$, as Proposition 21.8.2 allows. Then the set of tangent lines of C is the smooth conic of $\mathbb{P}(V^*)$ with matrix $\mathbf{A}^{-1}$.

Proof. The tangent at $[\mathbf{x}] \in C$ is the zero set of the functional $\mathbf{y} \mapsto \beta(\mathbf{x},\mathbf{y}) = \mathbf{x}^{\top}\mathbf{A}\mathbf{y}$, whose coordinate vector in the dual basis (Theorem 4.1.3) is $\mathbf{A}\mathbf{x}$. As $[\mathbf{x}]$ runs over C, the corresponding point of $\mathbb{P}(V^*)$ is $[\mathbf{A}\mathbf{x}]$ with $\mathbf{x}^{\top}\mathbf{A}\mathbf{x} = 0$. Since $\mathbf{A}$ is invertible, putting $\mathbf{z} = \mathbf{A}\mathbf{x}$ gives $\mathbf{x} = \mathbf{A}^{-1}\mathbf{z}$ and

$$0 = \mathbf{x}^{\top}\mathbf{A}\mathbf{x} = \mathbf{z}^{\top}(\mathbf{A}^{-1})^{\top}\mathbf{A}\mathbf{A}^{-1}\mathbf{z} = \mathbf{z}^{\top}\mathbf{A}^{-1}\mathbf{z},$$

using $(\mathbf{A}^{-1})^{\top} = (\mathbf{A}^{\top})^{-1} = \mathbf{A}^{-1}$. Conversely every non-zero $\mathbf{z}$ with $\mathbf{z}^{\top}\mathbf{A}^{-1}\mathbf{z} = 0$ arises this way, from $\mathbf{x} = \mathbf{A}^{-1}\mathbf{z}$, which satisfies $\mathbf{x}^{\top}\mathbf{A}\mathbf{x} = \mathbf{z}^{\top}\mathbf{A}^{-1}\mathbf{z} = 0$. The matrix $\mathbf{A}^{-1}$ is symmetric and invertible, so the set is a smooth conic. This proves the corollary. ∎

21.10.5 Lines in space: Plücker coordinates

The definition, the proposition, the theorem and the warning that follow work over **any** field; no characteristic hypothesis is needed, and none is used. Only the paragraph closing the subsection returns to quadrics, and it re-imposes $\operatorname{char} F \neq 2$ where it does.

Chapter 14 built the exterior powers and hinted that the $k \times k$ minors of an $n \times k$ matrix turn a k-dimensional subspace into a single point. Here it is. A line of $\mathbb{P}^3 = \mathbb{P}(F^4)$ is $\mathbb{P}(W)$ with $\dim W = 2$; a basis $(\mathbf{u},\mathbf{w})$ of W has a wedge $\mathbf{u}\wedge\mathbf{w} \in \Lambda^2 F^4$, which is non-zero by Theorem 14.8.7; and $\dim \Lambda^2 F^4 = \binom{4}{2} = 6$ by Theorem 14.8.5. So a line in space becomes a point of $\mathbb{P}^5$. The only questions are whether the point depends on the basis, whether different lines give different points, and which points of $\mathbb{P}^5$ occur.

Index convention. In this part we number the standard basis of F^4 as $\mathbf{e}_0,\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3$, matching the homogeneous coordinates $[x_0 : x_1 : x_2 : x_3]$ on $\mathbb{P}^3$, and we write $\mathbf{e}_{ij} = \mathbf{e}_i \wedge \mathbf{e}_j$ for $i < j$ and $\mathbf{e}_{0123} = \mathbf{e}_0 \wedge \mathbf{e}_1 \wedge \mathbf{e}_2 \wedge \mathbf{e}_3$.

Definition 21.10.3 — Plücker Coordinates of a Line

Let $L = \mathbb{P}(W)$ be a line of $\mathbb{P}^3$ and let $(\mathbf{u},\mathbf{w})$ be a basis of W. The **Plücker coordinates** of L relative to that basis are the six scalars

$$p_{ij} \coloneqq u_i w_j - u_j w_i, \qquad 0 \le i < j \le 3,$$

that is, the 2×2 minors of the 4×2 matrix with columns $\mathbf{u}$ and $\mathbf{w}$. By Theorem 14.9.5 they are the coordinates of the wedge:

$$\mathbf{u} \wedge \mathbf{w} = \sum_{i<j} p_{ij}\, \mathbf{e}_{ij}.$$

The point $[\mathbf{u}\wedge\mathbf{w}]\in\mathbb{P}(\Lambda^2F^4)=\mathbb{P}^5$ is the **Plücker point** of L, written $[L]$.

Proposition 21.10.8 — The Plücker Point Determines the Line

Let $L=\mathbb{P}(W)$ be a line of $\mathbb{P}^3$ and let $(\mathbf{u},\mathbf{w})$ be a basis of W.

(a) $\mathbf{u}\wedge\mathbf{w}\neq\mathbf{0}$, and $[\mathbf{u}\wedge\mathbf{w}]$ does not depend on the choice of basis $(\mathbf{u},\mathbf{w})$ of W, so $[L]$ is well defined.

(b) $W=\{\,\mathbf{v}\in F^4:\mathbf{v}\wedge\mathbf{u}\wedge\mathbf{w}=\mathbf{0}\,\}$. Consequently $L\mapsto[L]$ is injective on lines.

Proof.

(a) A basis is independent, so Theorem 14.8.7 gives $\mathbf{u}\wedge\mathbf{w}\neq\mathbf{0}$. Any other basis is $\mathbf{u}'=a\mathbf{u}+c\mathbf{w}$, $\mathbf{w}'=b\mathbf{u}+d\mathbf{w}$ for a change-of-basis matrix with columns (a,c) and (b,d), which is invertible, so $ad-bc\neq0$. Expanding,

$$\mathbf{u}'\wedge\mathbf{w}'=ad\,\mathbf{u}\wedge\mathbf{w}+cb\,\mathbf{w}\wedge\mathbf{u}=(ad-bc)\,\mathbf{u}\wedge\mathbf{w},$$

the terms $\mathbf{u}\wedge\mathbf{u}$ and $\mathbf{w}\wedge\mathbf{w}$ vanishing. A non-zero scalar multiple represents the same point of $\mathbb{P}^5$.

(b) By Theorem 14.8.7, $\mathbf{v}\wedge\mathbf{u}\wedge\mathbf{w}=\mathbf{0}$ exactly when $(\mathbf{v},\mathbf{u},\mathbf{w})$ is dependent, and since $(\mathbf{u},\mathbf{w})$ is independent this happens exactly when $\mathbf{v}\in\operatorname{span}(\mathbf{u},\mathbf{w})=W$. So W, hence L, is recovered from any representative of $[L]$; and if $[L]=[L']$ their representatives differ by a scalar, which does not change the set in the display, so $W=W'$ and $L=L'$. This proves the proposition.

■

Which points of $\mathbb{P}^5$ are Plücker points? Exactly one equation decides it.

Theorem 21.10.9 — The Plücker Relation and the Klein Quadric

Let F be any field and let $\mathbf{0}\neq\omega=\sum_{i<j}p_{ij}\mathbf{e}_{ij}\in\Lambda^2F^4$. Then $\omega=\mathbf{u}\wedge\mathbf{w}$ for some $\mathbf{u},\mathbf{w}\in F^4$ if and only if

$$p_{01}p_{23}-p_{02}p_{13}+p_{03}p_{12}=0. \tag{21.10.1}$$

Consequently $L\mapsto[L]$ is a **bijection** from the set of lines of $\mathbb{P}^3$ onto the set

$$\mathcal{K}\coloneqq\{\,[\omega]\in\mathbb{P}^5:p_{01}p_{23}-p_{02}p_{13}+p_{03}p_{12}=0\,\},$$

the **Klein quadric**.

Idea. ($\Rightarrow$) is an identity: substitute $p_{ij}=u_iw_j-u_jw_i$ and watch twelve terms cancel in six pairs. ($\Leftarrow$) needs a way to produce the two vectors, and the right one is to look for them in a kernel. The map $\mathbf{v}\mapsto\mathbf{v}\wedge\omega$ has a matrix, and pairing it against a second vector turns it into a bilinear form $B(\mathbf{v},\mathbf{v}')\,\mathbf{e}_{0123}=\mathbf{v}\wedge\mathbf{v}'\wedge\omega$ — which is alternating, because $\mathbf{v}\wedge\mathbf{v}=\mathbf{0}$. Two facts about alternating matrices then finish it: the determinant

of a 4×4 one is the square of its Pfaffian, which here is the left-hand side of Eq. 21.10.1, and the rank of an alternating matrix is even. A vanishing Pfaffian therefore drops the rank from 4 to 2, leaving a kernel of dimension 2, and the two vectors are there.

Proof. ($\Rightarrow$) Suppose $p_{ij} = u_i w_j - u_j w_i$. Expanding the three products,

$$\begin{aligned} p_{01}p_{23} &= u_0u_2w_1w_3 - u_0u_3w_1w_2 - u_1u_2w_0w_3 + u_1u_3w_0w_2,\\ p_{02}p_{13} &= u_0u_1w_2w_3 - u_0u_3w_1w_2 - u_1u_2w_0w_3 + u_2u_3w_0w_1,\\ p_{03}p_{12} &= u_0u_1w_2w_3 - u_0u_2w_1w_3 - u_1u_3w_0w_2 + u_2u_3w_0w_1. \end{aligned}$$

Each of the six monomials appears in exactly two of the three lines, and forming $p_{01}p_{23} - p_{02}p_{13} + p_{03}p_{12}$ cancels both copies every time. Monomial by monomial: $u_0u_2w_1w_3$ carries $+1$ in the first line and -1 in the third, contributing $(+1) - 0 + (-1) = 0$; $u_0u_3w_1w_2$ carries -1 in the first and -1 in the second, contributing $(-1)-(-1)+0 = 0$; $u_1u_2w_0w_3$ likewise $(-1) - (-1) + 0 = 0$; $u_1u_3w_0w_2$ gives $(+1) - 0 + (-1) = 0$; $u_0u_1w_2w_3$ gives $0 - 1 + 1 = 0$; and $u_2u_3w_0w_1$ gives $0 - 1 + 1 = 0$. The total is 0. This direction used nothing about F and did not need $\mathbf{u}\wedge\mathbf{w} \neq \mathbf{0}$.

($\Leftarrow$) Suppose $\omega \neq \mathbf{0}$ satisfies Eq. 21.10.1. Since $\dim \Lambda^4 F^4 = 1$ with basis $\mathbf{e}_{0123}$ (Corollary 14.8.6), there is a unique scalar $B(\mathbf{v},\mathbf{v}')$ with

$$\mathbf{v}\wedge\mathbf{v}'\wedge\omega = B(\mathbf{v},\mathbf{v}')\,\mathbf{e}_{0123},$$

where, expanding ω in the basis, $\mathbf{v}\wedge\mathbf{v}'\wedge\omega = \sum_{i<j} p_{ij}\,\mathbf{v}\wedge\mathbf{v}'\wedge\mathbf{e}_i\wedge\mathbf{e}_j$ is a combination of wedges of **four** vectors. So B is bilinear, the wedge being linear in each slot, and alternating: $B(\mathbf{v},\mathbf{v})\mathbf{e}_{0123} = \mathbf{v}\wedge\mathbf{v}\wedge\omega = \mathbf{0}$. Let $\mathbf{G}$ be its matrix in the basis $(\mathbf{e}_0,\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3)$; by Proposition 13.3.2 (b), $\mathbf{G}$ is an alternating matrix. Each entry is read off $\mathbf{e}_a\wedge\mathbf{e}_b\wedge\mathbf{e}_i\wedge\mathbf{e}_j$, which is $\pm\mathbf{e}_{0123}$ when $\{a,b,i,j\} = \{0,1,2,3\}$ and $\mathbf{0}$ otherwise: for instance $B(\mathbf{e}_0,\mathbf{e}_1) = p_{23}$ because only the term $\mathbf{e}_0\wedge\mathbf{e}_1\wedge\mathbf{e}_2\wedge\mathbf{e}_3 = \mathbf{e}_{0123}$ survives, and $B(\mathbf{e}_0,\mathbf{e}_2) = -p_{13}$ because $\mathbf{e}_0\wedge\mathbf{e}_2\wedge\mathbf{e}_1\wedge\mathbf{e}_3 = -\mathbf{e}_{0123}$ by Lemma 14.8.1 (a). In full,

$$\mathbf{G} = \begin{pmatrix} 0 & p_{23} & -p_{13} & p_{12}\\ -p_{23} & 0 & p_{03} & -p_{02}\\ p_{13} & -p_{03} & 0 & p_{01}\\ -p_{12} & p_{02} & -p_{01} & 0 \end{pmatrix}.$$

By Example (The Pfaffian in Sizes 2 and 4), a 4×4 alternating matrix with entries a,b,c,d,e,f above the diagonal, read in the order $a_{12},a_{13},a_{14},a_{23},a_{24},a_{34}$, has determinant $(af - be + cd)^2$. Here that reads

$$\det\mathbf{G} = \big(p_{23}p_{01} - (-p_{13})(-p_{02}) + p_{12}p_{03}\big)^2 = 0$$

by Eq. 21.10.1. So $\operatorname{rank}\mathbf{G} \le 3$, and $\operatorname{rank}\mathbf{G}$ is **even** by Corollary 13.9.3 (a), hence $\operatorname{rank}\mathbf{G} \le 2$.

Next, $\operatorname{rad}(B) = \{\mathbf{v} : \mathbf{v}\wedge\omega = \mathbf{0}\}$. Indeed if $\mathbf{v}\wedge\omega = \mathbf{0}$ then $B(\mathbf{v},\mathbf{v}') = 0$ for every $\mathbf{v}'$. Conversely suppose $\eta = \mathbf{v}\wedge\omega \neq \mathbf{0}$ and write $\eta = \sum_S c_S\mathbf{e}_S$ over the four 3-element subsets $S\subseteq\{0,1,2,3\}$, with some $c_S \neq 0$; let k be the index not in S. Then $\mathbf{e}_k\wedge\eta = \pm c_S\,\mathbf{e}_{0123} \neq \mathbf{0}$, every other term having a repeated factor. Exchanging the first two arguments of a wedge of four vectors changes its sign (Lemma 14.8.1 (a)), so $\mathbf{v}\wedge\mathbf{e}_k\wedge\omega = -\,\mathbf{e}_k\wedge\mathbf{v}\wedge\omega = -\,\mathbf{e}_k\wedge\eta \neq \mathbf{0}$, and therefore $B(\mathbf{v},\mathbf{e}_k) \neq 0$. (The two one-sided radicals agree because B is alternating, hence skew-symmetric by Theorem 13.3.3 (a).)

By Proposition 13.1.2 (b), $\dim \operatorname{rad}(B) = 4 - \operatorname{rank} \mathbf{G} \geq 2$. Choose independent $\mathbf{u}, \mathbf{w}$ with $\mathbf{u} \wedge \omega = \mathbf{w} \wedge \omega = \mathbf{0}$ and extend to a basis $(\mathbf{u}, \mathbf{w}, \mathbf{x}, \mathbf{y})$ of F^4 (Theorem 1.6.5). By Theorem 14.8.5 the six wedges of pairs from this basis form a basis of $\Lambda^2 F^4$, so

$$\omega = c_1\, \mathbf{u} \wedge \mathbf{w} + c_2\, \mathbf{u} \wedge \mathbf{x} + c_3\, \mathbf{u} \wedge \mathbf{y} + c_4\, \mathbf{w} \wedge \mathbf{x} + c_5\, \mathbf{w} \wedge \mathbf{y} + c_6\, \mathbf{x} \wedge \mathbf{y}.$$

Wedging with $\mathbf{u}$ kills the three terms containing $\mathbf{u}$ and leaves

$$\mathbf{0} = \mathbf{u} \wedge \omega = c_4\, \mathbf{u} \wedge \mathbf{w} \wedge \mathbf{x} + c_5\, \mathbf{u} \wedge \mathbf{w} \wedge \mathbf{y} + c_6\, \mathbf{u} \wedge \mathbf{x} \wedge \mathbf{y},$$

three distinct members of the basis of $\Lambda^3 F^4$ given by Theorem 14.8.5, hence independent; so $c_4 = c_5 = c_6 = 0$. Wedging what remains with $\mathbf{w}$,

$$\mathbf{0} = \mathbf{w} \wedge \omega = -c_2\, \mathbf{u} \wedge \mathbf{w} \wedge \mathbf{x} - c_3\, \mathbf{u} \wedge \mathbf{w} \wedge \mathbf{y},$$

so $c_2 = c_3 = 0$. Hence $\omega = c_1\, \mathbf{u} \wedge \mathbf{w}$ with $c_1 \neq 0$, and $\omega = (c_1 \mathbf{u}) \wedge \mathbf{w}$ is a wedge.

The bijection. If L is a line then $[L] = [\mathbf{u} \wedge \mathbf{w}]$ satisfies Eq. 21.10.1 by ($\Rightarrow$), and the relation is a homogeneous condition of degree 2, so it depends only on the point of $\mathbb{P}^5$. Injectivity is Proposition 21.10.8 (b). For surjectivity, let $[\omega] \in \mathcal{K}$. By ($\Leftarrow$), $\omega = \mathbf{u} \wedge \mathbf{w}$, and $\omega \neq \mathbf{0}$ forces $(\mathbf{u}, \mathbf{w})$ independent by Theorem 14.8.7, so $W = \operatorname{span}(\mathbf{u}, \mathbf{w})$ is 2-dimensional and $L = \mathbb{P}(W)$ is a line with $[L] = [\omega]$. This proves the theorem.

■

Remark. Chapter 14 reaches the same equation by a different route, in Exercise (C1: The Plücker relation): there $\omega \wedge \omega = 2\big(p_{01}p_{23} - p_{02}p_{13} + p_{03}p_{12}\big)\mathbf{e}_{0123}$, so in characteristic $\neq 2$ a decomposable ω, for which $\omega \wedge \omega = \mathbf{0}$, forces the bracket to vanish. That route is credited here, not used. The proof above stands on results proved in the text, and it needs no assumption on the characteristic, which the $\omega \wedge \omega$ route does; Exercise (C2: The Klein quadric) develops the $\omega \wedge \omega$ identity for its own sake.

Warning. **Not every point of $\mathbb{P}^5$ is a line.** The element $\omega = \mathbf{e}_{01} + \mathbf{e}_{23}$ has $p_{01} = p_{23} = 1$ and all other coordinates 0, so the left-hand side of Eq. 21.10.1 equals 1, and $1 \neq 0$ in every field. It is therefore not a wedge, and $[\omega] \notin \mathcal{K}$. Six numbers are two too many to describe a line freely; the relation removes one dimension and the projective scaling another.

When $\operatorname{char} F \neq 2$, the left-hand side of Eq. 21.10.1 is a quadratic form on the 6-dimensional space $\Lambda^2 F^4$, so $\mathcal{K}$ is a projective quadric in $\mathbb{P}^5$ in the exact sense of Definition 21.10.1. That is the sentence the section was built to reach: the set of all lines in three-dimensional space is itself a quadric, and everything proved about quadrics in the first half applies to it. Which quadric it is, Exercise (C2: The Klein quadric) works out: it computes the Gram matrix and finds the quadric smooth, with inertia $(3, 3, 0)$ over $\mathbb{R}$. That computation is left to the exercise, and nothing here rests on it.

Example. (A line, its Plücker point, and back)

Find the Plücker coordinates of the line L of $\mathbb{P}^3(\mathbb{Q})$ through $[1 : 0 : 1 : 0]$ and $[0 : 1 : 0 : 2]$, check the relation, and recover L from the coordinates.

Solution. With $\mathbf{u} = (1, 0, 1, 0)$ and $\mathbf{w} = (0, 1, 0, 2)$, the six minors are

$$\begin{aligned} p_{01} &= 1, \quad & p_{02} &= 0, \quad & p_{03} &= 2, \\ p_{12} &= -1, \quad & p_{13} &= 0, \quad & p_{23} &= 2, \end{aligned}$$

so $\mathbf{u} \wedge \mathbf{w} = \mathbf{e}_{01} + 2\mathbf{e}_{03} - \mathbf{e}_{12} + 2\mathbf{e}_{23}$. The relation holds:

$$p_{01}p_{23} - p_{02}p_{13} + p_{03}p_{12} = 1 \cdot 2 - 0 \cdot 0 + 2 \cdot (-1) = 0.$$

To go back, build the matrix $\mathbf{G}$ of the proof:

$$\mathbf{G} = \begin{pmatrix} 0 & 2 & 0 & -1 \\ -2 & 0 & 2 & 0 \\ 0 & -2 & 0 & 1 \\ 1 & 0 & -1 & 0 \end{pmatrix},$$

whose rank is 2: row 3 is -1 times row 1 and row 4 is $-\frac{1}{2}$ times row 2, while rows 1 and 2 are independent. Its null space is cut out by $2v_1 - v_3 = 0$ and $v_0 - v_2 = 0$, that is, by $v_2 = v_0$ and $v_3 = 2v_1$, and is spanned by $(1, 0, 1, 0)$ and $(0, 1, 0, 2)$ — the two points we started from, as Proposition 21.10.8 (b) promises.

21.10.6 Summary and transfer

The chapter began by removing the origin and ended by adding points at infinity, and both moves paid for themselves in theorems that have no exceptional cases. Four habits are worth carrying away.

A geometry is a group acting on a set, and the invariants name the subject. Affine maps preserve parallelism and ratios along a line; Euclidean motions preserve distance; projectivities preserve only incidence and the cross-ratio. Each time, the theorems of the geometry are exactly the statements its group cannot disturb, and the group was a matrix group in disguise: an $(n+1) \times (n+1)$ block matrix for the affine group, an orthogonal matrix plus a translation for motions, and $\mathrm{GL}(V)$ modulo scalars for projectivities.

Adding points removes cases. The affine formula for the dimension of a join needed two cases; its projective counterpart needs none. Two lines in a projective plane always meet. A quadratic form in three variables has one classification list, not a longer one split by whether a center exists. The extra points cost nothing, since $\mathbb{P}(V)$ is built from the same vector space.

Choose the representative. A point of $\mathbb{P}(V)$ is a line of vectors, and nearly every projective proof in this chapter began by picking one vector per point so that the hypothesis became an equation: $\mathbf{a}' = \mathbf{a} + \mathbf{o}$ in Desargues, $\mathbf{u} + t\mathbf{o}$ in Pappus, the normalized second intersection point in the conic parametrization. The choice is where the content is, and it is worth stating out loud each time which scalings are still free afterwards.

Homogeneous means algebraic. A condition that survives scaling is a condition on $\mathbb{P}(V)$: $q(\mathbf{x}) = 0$, the Plücker relation, membership of a subspace. That is why each of the objects in this chapter turned out to be the solution set of homogeneous polynomial equations — and the last of them, the Klein quadric, made the lines of $\mathbb{P}^3$ into points of a quadric in $\mathbb{P}^5$, so that a question about lines becomes a question about a symmetric matrix. Chapter 13's classification of forms and Chapter 14's exterior powers were the two tools that made it possible, and neither was built with geometry in mind.

What the chapter did **not** do is also worth recording. It developed no analysis of its own: no limits and no continuity arguments. The only topological words used inside a proof, in Section 3, are quoted from Chapters 15 and 17's theorems, and nothing is said about the topology of $\mathbb{P}^2(\mathbb{R})$, which is a subject of its own. Quadrics required $\operatorname{char} F \neq 2$ everywhere, as Chapter 13 warned they would; Desargues, Pappus and the Plücker correspondence did not. And the axiomatic side of projective geometry — planes not of the form $\mathbb{P}(V)$, coordinatization by division rings — was pointed at once, in Section 9, and proved nowhere.

21.10.7 Exercises

21.10.7.1 A. Check your understanding

Exercise A1.

(a) State Definition 21.10.1 and say why the zero set is well defined on $\mathbb{P}(V)$.

(b) Which invariant classifies quadrics over an algebraically closed field, and which over $\mathbb{R}$?

(c) List the five projective equivalence classes of conics in $\mathbb{P}^2(\mathbb{R})$ with their zero sets.

(d) State the Plücker relation, and say what the six coordinates are the minors of.

(e) True or false, with a reason: a smooth conic over $\mathbb{R}$ is never empty.

Solution.

(a) The zero set $Z(q) = \{[\mathbf{x}] : q(\mathbf{x}) = 0\}$ of a non-zero quadratic form q, over a field of characteristic $\neq 2$. It is well defined because $q(\lambda\mathbf{x}) = \lambda^2 q(\mathbf{x})$, so for $\lambda \neq 0$ one value is zero exactly when the other is.

(b) Rank alone over an algebraically closed field (Theorem 21.10.1 (a)); rank together with inertia up to interchanging n_+ and n_- over $\mathbb{R}$ (part (b) of the same theorem).

(c) By Corollary 21.10.2 (b): $(1,0)$ a line; $(2,0)$ a point; $(1,1)$ two distinct lines; $(3,0)$ the empty set; $(2,1)$ a smooth non-empty conic.

(d) $p_{01}p_{23} - p_{02}p_{13} + p_{03}p_{12} = 0$, where the p_{ij} are the six 2×2 minors of the 4×2 matrix whose columns are two points spanning the line.

(e) False. $x_0^2 + x_1^2 + x_2^2$ has rank 3, so its conic is smooth, and the zero set in $\mathbb{P}^2(\mathbb{R})$ is empty.

21.10.7.2 B. Practice

Exercise B1: Classify these conics.

Classify each of the following conics of $\mathbb{P}^2$ over $\mathbb{R}$ and over $\mathbb{C}$, giving the rank, the real inertia and the zero set. Justify your answer.

(a) $2x_0x_1 + 2x_0x_2 + 2x_1x_2 = 0$.

(b) $x_0^2 + 2x_0x_1 + x_1^2 = 0$.

(c) $x_0^2 + 2x_0x_1 + x_1^2 + x_2^2 = 0$.

Solution.

(a) Put $y_0 = x_0+x_1$ and $y_1 = x_0-x_1$, so $2x_0x_1 = \tfrac{1}{2}(y_0^2-y_1^2)$ and $2x_0x_2+2x_1x_2 = 2y_0x_2$. Then
$$q = \tfrac{1}{2}\big(y_0^2 + 4y_0x_2\big) - \tfrac{1}{2}y_1^2 = \tfrac{1}{2}(y_0 + 2x_2)^2 - 2x_2^2 - \tfrac{1}{2}y_1^2.$$
The three forms $y_0 + 2x_2 = x_0 + x_1 + 2x_2$, $y_1 = x_0 - x_1$ and x_2 are independent, the matrix with those rows having determinant -2. So the rank is 3 and the real inertia is $(1, 2, 0)$, which is $(2, 1, 0)$ after a sign change; by Corollary 21.10.2 the zero set is a smooth non-empty conic over $\mathbb{R}$ and a smooth conic over $\mathbb{C}$. For instance $[1 : 0 : 0]$ lies on it, every term of q having a factor x_1 or x_2.

(b) $q = (x_0 + x_1)^2$, rank 1, inertia $(1, 0, 2)$. The zero set is the line $\{x_0 + x_1 = 0\}$ over either field.

(c) $q = (x_0 + x_1)^2 + x_2^2$, rank 2, inertia $(2, 0, 1)$. Over $\mathbb{R}$ the zero set is the single point $[1 : -1 : 0]$. Over $\mathbb{C}$ the form factors as $(x_0 + x_1 + ix_2)(x_0 + x_1 - ix_2)$, so the zero set is two distinct lines.

Exercise B2: A conic through five points.

Find the conic of $\mathbb{P}^2(\mathbb{Q})$ through $[1 : 0 : 0]$, $[0 : 1 : 0]$, $[0 : 0 : 1]$, $[1 : 1 : 1]$ and $[1 : -1 : 2]$, verify that no three of the five points are collinear, and decide whether the conic is smooth.

Solution. Write $q = ax_0^2 + bx_1^2 + cx_2^2 + dx_0x_1 + ex_0x_2 + fx_1x_2$. The three standard basis points give $a = b = c = 0$. Then $[1 : 1 : 1]$ gives $d + e + f = 0$ and $[1 : -1 : 2]$ gives $-d + 2e - 2f = 0$. Adding, $3e - f = 0$, so $f = 3e$ and $d = -e - f = -4e$. Taking $e = 1$,
$$q = -4x_0x_1 + x_0x_2 + 3x_1x_2.$$
No three of the five are collinear: the determinants of the 3×3 matrices formed by any three of the five coordinate vectors are, in the order 123, 124, 125, 134, 135, 145, 234, 235, 245, 345,
$$1,\ 1,\ 2,\ -1,\ 1,\ 3,\ 1,\ 1,\ -1,\ -2,$$
none of them zero.

The matrix is
$$\mathbf{A} = \begin{pmatrix} 0 & -2 & 1/2 \\ -2 & 0 & 3/2 \\ 1/2 & 3/2 & 0 \end{pmatrix}, \qquad \det \mathbf{A} = -3 \neq 0,$$
so the conic is smooth, and by the argument of Example (A conic through five points) (product of eigenvalues negative, trace zero) its real inertia is $(2, 1, 0)$.

Exercise B3: Plücker coordinates.

(a) Compute the Plücker coordinates of the line of $\mathbb{P}^3(\mathbb{Q})$ through $[1 : 1 : 0 : 0]$ and $[0 : 0 : 1 : 1]$, and check Eq. 21.10.1.

(b) Determine whether $[\omega]$ with $(p_{01}, p_{02}, p_{03}, p_{12}, p_{13}, p_{23}) = (1, 0, 0, 0, 0, 1)$ is the Plücker point of a line. Justify your answer.

(c) The six numbers $(1, 1, 0, 0, -1, -1)$, in the same order, satisfy Eq. 21.10.1. Find

the line they come from.

Solution.

(a) With $\mathbf{u} = (1,1,0,0)$ and $\mathbf{w} = (0,0,1,1)$,

$$p_{01} = 0, \quad p_{02} = 1, \quad p_{03} = 1,$$
$$p_{12} = 1, \quad p_{13} = 1, \quad p_{23} = 0,$$

and $0 \cdot 0 - 1 \cdot 1 + 1 \cdot 1 = 0$.

(b) No. The left-hand side of Eq. 21.10.1 is $1 \cdot 1 - 0 + 0 = 1 \neq 0$, so by Theorem 21.10.9 the element $\mathbf{e}_{01} + \mathbf{e}_{23}$ is not a wedge and its point is not on the Klein quadric.

(c) First, $1 \cdot (-1) - 1 \cdot (-1) + 0 \cdot 0 = 0$, as stated. Build $\mathbf{G}$ as in the proof of Theorem 21.10.9:

$$\mathbf{G} = \begin{pmatrix} 0 & -1 & 1 & 0 \\ 1 & 0 & 0 & -1 \\ -1 & 0 & 0 & 1 \\ 0 & 1 & -1 & 0 \end{pmatrix}.$$

Its null space is given by $-v_1 + v_2 = 0$ and $v_0 - v_3 = 0$, so it is spanned by $(1,0,0,1)$ and $(0,1,1,0)$. The line is the one through $[1:0:0:1]$ and $[0:1:1:0]$; as a check, its minors are $p_{01} = 1$, $p_{02} = 1$, $p_{03} = 0$, $p_{12} = 0$, $p_{13} = -1$, $p_{23} = -1$, as given.

21.10.7.3 C. Going deeper

Exercise C1: All rational points of a circle.

Work in $\mathbb{P}^2(\mathbb{Q})$ with $C = Z(x_0^2 + x_1^2 - x_2^2)$.

(a) Prove that C is smooth and that $P_0 = [0:1:1]$ lies on it.

(b) Using Theorem 21.10.5 with $\ell = \{x_1 = 0\}$, compute the resulting parametrization of C explicitly.

(c) Deduce that every solution of $a^2 + b^2 = c^2$ in integers with $c \neq 0$ is a rational multiple of $(2uv,\ u^2 - v^2,\ u^2 + v^2)$ for some integers u, v, and exhibit the triple obtained at $[u:v] = [2:1]$.

Solution.

(a) The matrix is $\operatorname{diag}(1,1,-1)$, invertible, so C is smooth; and $0 + 1 - 1 = 0$, so $P_0 \in C$. Also $P_0 \notin \ell$, since its x_1-coordinate is $1 \neq 0$.

(b) Here $\mathbf{p} = (0,1,1)$ and $\beta(\mathbf{x},\mathbf{y}) = x_0y_0 + x_1y_1 - x_2y_2$. A point of ℓ is $[u:0:v]$, with $q(\mathbf{x}) = u^2 - v^2$ and $\beta(\mathbf{p},\mathbf{x}) = -v$. So

$$\begin{aligned} \psi([u:0:v]) &= \big[-(u^2 - v^2)(0,1,1) - 2v(u,0,v)\big] \\ &= \big[-2uv \ : \ v^2 - u^2 \ : \ -u^2 - v^2\big] \\ &= \big[2uv \ : \ u^2 - v^2 \ : \ u^2 + v^2\big]. \end{aligned}$$

Indeed $(2uv)^2 + (u^2 - v^2)^2 = (u^2 + v^2)^2$.

(c) Let $a^2 + b^2 = c^2$ with a, b, c integers and $c \neq 0$. Then $[a:b:c]$ is a point

of C with rational coordinates, so by Theorem 21.10.5 it equals $\psi([u:0:v])$ for exactly one point of ℓ, which has rational, hence after clearing denominators integer, coordinates u, v. Therefore (a, b, c) is a rational multiple of $(2uv,\ u^2 - v^2,\ u^2 + v^2)$. At $[u:v] = [2:1]$ this is $(4, 3, 5)$.

Exercise C2: The Klein quadric.

Let $\operatorname{char} F \neq 2$, write $Q(\omega) = p_{01}p_{23} - p_{02}p_{13} + p_{03}p_{12}$ for $\omega \in \Lambda^2 F^4$, and let β_Q be the symmetric bilinear form with $\beta_Q(\omega, \omega) = Q(\omega)$, which exists and is unique by Theorem 13.3.5.

(a) Prove that $\omega \wedge \omega = 2Q(\omega)\,\mathbf{e}_{0123}$ for every $\omega \in \Lambda^2 F^4$, and deduce $\omega \wedge \omega' = 2\beta_Q(\omega, \omega')\,\mathbf{e}_{0123}$.

(b) Prove that two lines L, L' of $\mathbb{P}^3$ meet if and only if $\beta_Q([L], [L']) = 0$, the value being computed from any representatives.

(c) Compute the matrix of β_Q in the basis ordered $(\mathbf{e}_{01}, \mathbf{e}_{23}, \mathbf{e}_{02}, \mathbf{e}_{13}, \mathbf{e}_{03}, \mathbf{e}_{12})$. Deduce that Q has rank 6, so that the Klein quadric is smooth, and that over $\mathbb{R}$ its inertia is $(3, 3, 0)$.

Hint: for (a), expand and note that only complementary pairs of index sets survive; the same computation appears in Exercise (C1: The Plücker relation) (a).

Solution.

(a) Expanding $\omega \wedge \omega = \sum_{S,T} p_S p_T\, \mathbf{e}_S \wedge \mathbf{e}_T$ over 2-element index sets, a term vanishes unless S and T are disjoint, so only the pairs $\{01\}, \{23\}$, $\{02\}, \{13\}$, $\{03\}, \{12\}$ and their reverses survive. A reversal does not change $\mathbf{e}_S \wedge \mathbf{e}_T$ for $|S| = |T| = 2$: passing each of the two factors of $\mathbf{e}_T$ across the two factors of $\mathbf{e}_S$ costs four transpositions, and a permutation that is a product of four transpositions has sign $+1$ (Corollary 6.3.3), so by Lemma 14.8.1 (b) the value is unchanged. Sorting, $\mathbf{e}_{01} \wedge \mathbf{e}_{23} = \mathbf{e}_{0123}$, $\mathbf{e}_{02} \wedge \mathbf{e}_{13} = -\mathbf{e}_{0123}$ (one transposition) and $\mathbf{e}_{03} \wedge \mathbf{e}_{12} = \mathbf{e}_{0123}$ (two). So $\omega \wedge \omega = 2(p_{01}p_{23} - p_{02}p_{13} + p_{03}p_{12})\mathbf{e}_{0123}$.
For the second identity expand $(\omega + \omega') \wedge (\omega + \omega')$ in two ways. Wedging is symmetric on 2-vectors, by bilinearity and the remark just made, so the cross terms combine: $2Q(\omega + \omega')\mathbf{e}_{0123} = 2Q(\omega)\mathbf{e}_{0123} + 2\,\omega \wedge \omega' + 2Q(\omega')\mathbf{e}_{0123}$. Since $\beta_Q(\omega, \omega') = \frac{1}{2}\big(Q(\omega + \omega') - Q(\omega) - Q(\omega')\big)$ by Theorem 13.3.5, this rearranges to $\omega \wedge \omega' = 2\beta_Q(\omega, \omega')\mathbf{e}_{0123}$.

(b) Write $L = \mathbb{P}(W)$, $L' = \mathbb{P}(W')$ with bases $(\mathbf{u}, \mathbf{w})$ and $(\mathbf{u}', \mathbf{w}')$. By (a), $\beta_Q = 0$ on the pair exactly when $\mathbf{u} \wedge \mathbf{w} \wedge \mathbf{u}' \wedge \mathbf{w}' = \mathbf{0}$, which by Theorem 14.8.7 happens exactly when $(\mathbf{u}, \mathbf{w}, \mathbf{u}', \mathbf{w}')$ is dependent, that is, when $\dim(W + W') \leq 3$. By Theorem 1.7.3 this says $\dim(W \cap W') \geq 2 + 2 - 3 = 1$, which says $L \cap L' \neq \emptyset$. Rescaling a representative rescales β_Q by a non-zero factor, so vanishing does not depend on the choice.

(c) In that order the matrix is block diagonal with the three 2×2 blocks

$$\begin{pmatrix} 0 & 1/2 \\ 1/2 & 0 \end{pmatrix}, \qquad \begin{pmatrix} 0 & -1/2 \\ -1/2 & 0 \end{pmatrix}, \qquad \begin{pmatrix} 0 & 1/2 \\ 1/2 & 0 \end{pmatrix},$$

since Q is a sum of three products of complementary coordinates. Each block has determinant $-1/4 \neq 0$, so the whole matrix is invertible and $\operatorname{rank} Q = 6$: the

quadric is smooth. Over $\mathbb{R}$ each block has eigenvalues $\pm 1/2$, one positive and one negative, so the inertia is $(3, 3, 0)$.

Chapter 22

Algebras and Representations

Twenty-one chapters have studied operators one at a time, or in commuting families. Chapter 8 asked for a basis in which a single operator is simple and found eigenvectors; Chapter 9 finished the question with the Jordan and rational forms; Chapters 10 to 12 answered it again with an inner product to respect. Then the question widened once, in Chapter 8 §09 and Chapter 11 §07: one basis good for a whole commuting family at a time. This chapter widens it once more, and to the last setting in which the question still has a clean answer — a set of operators closed under addition, under scalars, and under composition, with no assumption that its members commute. Such a set is an **algebra**, and the chapter's main theorem says that over an algebraically closed field there is essentially one building block, a full matrix algebra, and that everything semisimple is a product of those.

Nothing forced the earlier stopping point except habit. The polynomials in a fixed operator form an algebra; so do the circulants of Chapter 11 §09, the matrices commuting with a given matrix, the upper triangular matrices, the block diagonal matrices, and the linear symmetries of a figure. Every one of those the book has met and handled separately. What they have in common is the only thing this chapter needs, and naming it is most of the work.

The second half is the same statement read for groups. A group cannot be added, so linear algebra cannot reach it directly; but the formal combinations of group elements do form an algebra, the **group algebra** $F[G]$, and a group acting by invertible operators is exactly a representation of that algebra. Everything proved about algebras then applies word for word. Maschke's theorem says $F[G]$ is semisimple as soon as the characteristic of F does not divide $|G|$; the structure theorem splits it into matrix blocks; and the traces of those blocks — the **characters** — turn out to be an orthonormal basis of the functions that are constant on conjugacy classes. One square array of numbers then records every complex representation of the group, up to equivalence, and the number of rows is the number of conjugacy classes.

One debt is paid in full. For a finite abelian group every block has size one, the character table is a single unitary matrix, and for the cyclic group that matrix is Chapter 11 §09's Fourier matrix, entry for entry. The discrete Fourier transform, the convolution theorem, and "every circulant is a polynomial in the shift" were representation theory all along, and §09 proves each of the three identifications.

This is the last of the book's chapters of general theory. The chapter that follows is about arithmetic, algorithms and applications, and nothing here depends on it.

22.0.1 Conventions

- **Algebras are associative, unital and finite-dimensional over** F, unless a statement says otherwise. The one standing exception is $F[x]$, kept as a source of counterexamples and always named as infinite-dimensional where it is used that way. Nothing requires commutativity, and nothing requires a non-zero element to have an inverse: an algebra is not a group, and §01 closes with a warning to that effect.
- **The definition is already in the book.** Chapter 13 §12's Definition 13.12.1 is used as it stands; §01 builds on it rather than restating it, adding Definition 22.1.1, Definition 22.1.2, Definition 22.1.3 and Definition 22.1.4.
- $\mathcal{L}(V)$ **and** $\mathrm{End}(V)$ **name the same object.** The book's default is $\mathcal{L}(V)$; §§05, 06 and 07 write $\mathrm{End}(V)$ where the algebra structure is the point. Likewise $\mathrm{End}_A(V) \subseteq \mathcal{L}(V)$, with the subscript never dropped, is the set of maps respecting an action of A.
- $F\langle S\rangle$ **is the subalgebra generated by** S and $\langle p\rangle$, without the F, is Chapter 5's ideal generated by p. They are different and usually different sizes; §01 says so where the notation is introduced.
- S' **is the commutant**, the set of elements commuting with every member of S; $S'' = (S')'$ is the double commutant, and $Z(A) = A'$ is the center. The definition asks nothing of S — not that it be a subspace, not that its own members commute.
- **"Simple" is two words.** An **algebra** is simple when its only two-sided ideals are $\{0\}$ and itself; a **space** on which an algebra acts is simple, equivalently irreducible, when its only invariant subspaces are $\{\mathbf{0}\}$ and itself. Neither implies the other, and §03 opens with the warning and the witness. **"Irreducible" is three words**, since Chapter 5 calls a polynomial irreducible (Definition 5.3.1) and Chapter 18 §02 calls a non-negative matrix irreducible; §03's proof of Theorem 22.3.7 uses the first and the second within two lines of each other, and the argument is what tells them apart.
- **"Semisimple" is three words, and §03 reconciles them.** An algebra **acts semisimply on a space** when every invariant subspace has an invariant complement; an **algebra is semisimple** when it acts semisimply on itself, that is, when every left ideal has a complementary left ideal; and Chapter 9 §08 called an **operator** semisimple when its minimal polynomial is a product of distinct irreducibles. Theorem 22.3.7 proves the third is the first, applied to $F[T]$.
- $\mathrm{rad}\, A$ **is the radical of an algebra** (Definition 22.3.5), the set of elements killed by every irreducible representation. Chapter 13 §01's $\mathrm{rad}(\beta)$ is the radical of a bilinear form; the argument tells them apart and they never meet.
- $\mathbf{E}_{ij}$ **is the matrix unit** with a 1 in position (i, j), and δ_g is the basis vector of $F[G]$ attached to the group element g, so that $\delta_g\delta_h = \delta_{gh}$. The Kronecker delta always carries two numerical subscripts, δ_{jk}, and no group element is ever written as a pair of numbers.
- **Groups are finite from §07 on**, written multiplicatively. $\chi_\rho(g) = \mathrm{tr}\,\rho(g)$ is the character of a representation; only for an abelian group is a character a homomorphism, and §09 says so before adopting that reading and writing $\widehat{G}$ for the group of them.

22.0.1.1 Which field, and where the hypothesis bites

Most theorems in this chapter are false over the wrong field, and it is worth saying once, exactly, which ones need what. §10 sets the same information out as a table, with a counterexample in every row.

Sections 1, 2 and 3 work over an arbitrary field F**, with no hypothesis at all.** That includes the chapter's first real theorem, Theorem 22.2.2, whose proof uses nothing about F beyond the existence of inverses of non-zero scalars; the classification of the left ideals of $M_n(F)$;

the first isomorphism theorem for algebras; and Theorem 22.3.3, which is the section's engine and holds over $\mathbb{F}_2$ as readily as over $\mathbb{C}$.

Algebraic closure is asked for at exactly five places. The second half of Schur's lemma, Theorem 22.4.1 (b), and its three corollaries Corollary 22.4.3, Corollary 22.4.4 and Corollary 22.4.5; Burnside's theorem Theorem 22.5.2; and Wedderburn's structure theorem Theorem 22.6.1. In every one of them the hypothesis buys the same single thing — an operator on a non-zero space has an eigenvalue — and that is the only thing it buys. The **first** half of Schur's lemma needs nothing of the field and is used over arbitrary fields. **The double commutant theorem needs nothing of the field either**: Theorem 22.5.5 holds over every F, and what it asks instead is that A act semisimply and contain id_V. Both of those are shown by §05 to be necessary.

One matrix is the witness for every failure of algebraic closure. Rotation of $\mathbb{R}^2$ through $2\pi/n$ with $n \geq 3$ has no real eigenvalue. The algebra it generates is commutative, it acts irreducibly on $\mathbb{R}^2$, its commutant is a copy of $\mathbb{C}$ rather than $\mathbb{R}$, and it is a two-dimensional subalgebra of $M_2(\mathbb{R})$ and so is not all of $\mathrm{End}(\mathbb{R}^2)$. That one example breaks Schur's second half, breaks the corollary that irreducible plus commutative means one-dimensional, and breaks Burnside. §04 computes the commutant in full.

A hypothesis on the characteristic enters only with groups, and only in one theorem. Theorem 22.7.3 needs $\mathrm{char}\, F \nmid |G|$, because its proof divides by $|G|$; the witness is $\mathbb{Z}/p\mathbb{Z}$ acting on $\mathbb{F}_p^2$ by unipotent matrices, where the invariant line has no invariant complement. Finiteness of G is used twice over — to average and to count — and §07 shows $\mathbb{Z}$ acting on $\mathbb{Q}^2$ failing in characteristic zero for the other reason. Everything in §07 up to that point is over an arbitrary field.

Sections 8 and 9 fix $F = \mathbb{C}$ throughout, where both hypotheses hold at once and neither can fail: $\mathbb{C}$ is algebraically closed, so Schur's lemma gives scalars, and $\mathrm{char}\, \mathbb{C} = 0$ divides no group order, so the averaging is legal. That is why the complex theory is so much cleaner than the general one. The modular case, where the characteristic does divide $|G|$, is a different subject and the chapter does not enter it.

One further hypothesis is local. Proposition 22.4.6, which says an algebra closed under adjoints acts semisimply, lives on a real or complex inner product space; it is the reason Chapter 11 §07 needed no averaging, and it is used nowhere else.

22.0.2 What the chapter quotes, and what it does not prove

The chapter imports no analysis. No limit, no continuity, no compactness argument appears in it, and it adds nothing to the list of analytic facts **(A1)–(A6)** that Chapter 15 introduced — Chapter 15's numbering, not §01's algebra axioms (A1)–(A3) — it does not use that list at all. Roots of unity are Chapter 0 §06's complex numbers and nothing more.

Six things are quoted with credit and proved nowhere in the book. Each is flagged again where it appears, and **nothing in the chapter rests on any of them.** No theorem here rests on an exercise either; where an exercise is pointed at, the text says that an exercise is not a proof.

- **Section 6 — the Wedderburn–Artin theorem over a division ring**: that a finite-dimensional semisimple algebra over *any* field is a product $M_{n_1}(D_1) \times \cdots \times M_{n_k}(D_k)$ with each D_i a division algebra. The chapter proves only the algebraically closed case, where

every D_i is F. The reason given is the honest one: the book has never built division rings, and the quaternions are one example, not a theory.

- **Section 6 — Wedderburn's little theorem**, that a finite division ring is a field. Same reason. Its effect on the theorem above is recorded and then not used.
- **Section 8 — that the character table does not determine the group.** Two non-isomorphic groups of order 8, the symmetries of a square and the unit quaternions, have identical tables. §08 names them in a warning and constructs neither; the book has neither the group theory to do it nor any need of the fact. What the character table *does* determine — every complex representation of the group up to equivalence — is proved, in Corollary 22.8.8.
- **Section 9 — the structure theorem for finite abelian groups**, that every one is a direct product of cyclic groups. What §09 actually proves is $|\widehat{G}| = |G|$ for every finite abelian G (Proposition 22.9.3), and $\widehat{G} \cong G$ for cyclic groups and for finite direct products of them (Theorem 22.9.4). The general isomorphism is stated as true and not proved, and §09 says which of its later statements would need it: none. The remark points at Chapter 9 §07's Smith normal form as the linear-algebra shadow of the missing argument, and at an exercise there, and adds that the exercise assumes an input it does not prove.
- **Section 3 — the converse of Proposition 22.3.6**, that a finite-dimensional algebra with zero radical is semisimple. Not proved and never used: whenever semisimplicity is needed later it is established directly, by Maschke's theorem or by exhibiting a decomposition.
- **Section 1 — when the commutant of a single matrix is the algebra of polynomials in it.** The exact condition is that the minimal and characteristic polynomials agree. §01 computes two commutants where they do and one where they do not, states the criterion in a remark with credit, and proves nothing about it.

Two further names are mentioned and no statement of theirs is used. §05 records that its proof of the double commutant theorem is the finite-dimensional shadow of Jacobson's density theorem, and that there is an analytic theorem of the same shape, von Neumann's, for operators on a Hilbert space. Neither is proved and neither is needed.

Four neighboring subjects are left outside on purpose, and §10 lists them with the reason in each case: induced representations and Frobenius reciprocity, which need cosets of a subgroup that Chapter 0 does not have; modular representation theory, which is what happens when Maschke's theorem fails; character tables as a computational craft, of which the chapter computes three small ones; and representations of infinite groups, where every proof here loses both of its uses of finiteness.

22.0.3 What you need

The chapter leans on Chapters 0 to 5 and on Chapters 8, 9 and 11, and takes one or two facts each from Chapters 6, 7, 10, 13 and 14. **Chapters 12 and 15 to 21 are not cited anywhere in it.** No norm, no singular value, no positive semidefinite matrix, no matrix inequality, no convexity and no geometry appears at any point. Eigenvalues enter only through Chapter 8, and almost always through one fact: over an algebraically closed field, an operator on a non-zero space has one.

Chapter 0 §10 is all the group theory the book has — groups, subgroups, homomorphisms, the symmetric group and cycle notation, and nothing else. There is no Lagrange's theorem, no coset of a subgroup and no quotient group. Where this chapter needs more than that, it builds it in place and says so: conjugacy classes, and the proof that they partition

the group, in §08; the order of an element and the cyclic subgroup it generates, and the direct product of two groups, in §09; and, in an exercise of §01, the class sums that span the center of $F[G]$.

- **Chapter 0** — matrix multiplication and the three views of a product, which carry §01's and §02's computations with matrix units; the characteristic of a field and the arithmetic of integer multiples of 1_F, which is exactly Maschke's hypothesis; the complex numbers and their roots of unity, which are every value a character takes; and equivalence relations and partitions, for the conjugacy classes: Definition 0.9.9, Theorem 0.9.4, Theorem 0.9.2, Definition 0.7.2, Lemma 0.7.4, Theorem 0.8.5, Example (Roots of Unity), Theorem 0.6.4, Definition 0.5.2, Theorem 0.5.2, Theorem 0.2.3, Theorem 0.2.10, Definition 0.10.1, Definition 0.10.2, Definition 0.10.3, Example (Groups), Example (Computing with cycles), Theorem 0.10.1, Theorem 0.10.3, Theorem 0.10.2, Theorem 0.10.4.
- **Chapter 1** — the constant companion: subspaces, spans, bases and dimension, and above all the direct sum criteria, since every decomposition theorem in the chapter is a statement that some sum is direct. Theorem 1.7.6 supplies the ordinary complement that Maschke's averaging repairs, and Theorem 1.6.8 is how a minimal invariant subspace is recognized as irreducible: Example (The Standard Vector Spaces), Theorem 1.2.1, Theorem 1.2.2, Definition 1.3.2, Theorem 1.3.1, Example (Standard Bases), Theorem 1.6.5, Theorem 1.6.8, Theorem 1.6.4, Theorem 1.7.6, Theorem 1.7.4, Theorem 1.7.5, Theorem 1.7.3.
- **Chapter 2** — three facts. Permutation matrices are how the symmetric group becomes operators, and the theorem that a one-sided inverse of a square matrix is two-sided is what turns the row orthogonality of characters into column orthogonality in one line: Definition 2.6.2, Lemma 2.6.6, Theorem 2.4.5.
- **Chapter 3** — the workhorse, and the chapter's largest debt after Chapter 1. Kernels and images give every invariance argument; Rank–Nullity is used in four sections; products and quotients of spaces give the quotient algebra, the first isomorphism theorem and the n-fold copy in the proof of the double commutant theorem; the matrix of a map turns $\mathcal{L}(V)$ into $M_n(F)$ as algebras; and projections and the trace are the whole of §08: Theorem 3.1.6, Theorem 3.2.1, Theorem 3.2.2, Theorem 3.2.3, Theorem 3.3.1, Theorem 3.4.2, Theorem 3.5.1, Theorem 3.5.3, Theorem 3.5.4, Theorem 3.6.4, Theorem 3.6.2, Definition 3.9.1, Definition 3.9.3, Theorem 3.9.1, Theorem 3.9.5, Theorem 3.9.7, Definition 3.10.1, Theorem 3.10.1, Definition 3.10.2, Theorem 3.10.3, Theorem 3.10.4.
- **Chapter 4** — the dual space, in two places. Burnside's proof runs on rank-one operators written as $\mathbf{v}\varphi$, so it needs a dual basis and $\dim V^* = \dim V$; and the annihilator and the dual map appear in the exercises of §§02 and 07, which classify the right ideals of $M_n(F)$ and build the contragredient representation: Theorem 4.1.1, Definition 4.1.3, Corollary 4.1.4, Definition 4.2.1, Theorem 4.2.3, Theorem 4.2.2, Corollary 4.3.5, Definition 4.4.1, Theorem 4.4.1, Theorem 4.6.7.
- **Chapter 5** — polynomials. Division with remainder and the minimal polynomial give $\dim F[T] = \deg m_T$; the ideals of $F[x]$ are the commutative model §02 generalizes; unique factorization and the primary decomposition are what §03 needs to identify Chapter 9's semisimple operator with this chapter's; the Fundamental Theorem of Algebra is where "algebraically closed" is grounded; and Lagrange interpolation writes the projections onto the eigenspaces of a diagonalizable operator as polynomials in it, which is how §05 computes a commutant: Theorem 5.1.1, Theorem 5.1.3, Definition 5.2.1, Example (First Ideals), Proposition 5.2.1, Definition 5.3.1, Theorem 5.3.5, Theorem 5.5.1, Theorem 5.6.5, Theorem 5.6.1, Theorem 5.7.3, Theorem 5.7.1.
- **Chapter 6 §03** — one fact, used for one representation: the sign of a permutation is multiplicative, which is what makes the sign representation of S_n a representation: Definition 6.3.2, Theorem 6.3.1.
- **Chapter 7 §01** — one fact: block diagonal matrices multiply blockwise, which is how

§06 recognizes a product of matrix algebras inside $M_n(F)$: Theorem 7.1.4.

- **Chapter 8** — invariant subspaces, eigenvalues and the commuting-operator theorems this chapter re-derives and explains. Theorem 8.2.1 and Theorem 8.2.4 are the single fact algebraic closure is spent on; Theorem 8.8.1 and the cyclic machinery settle §03's comparison with Chapter 9; and §§04 and 10 look back at Theorem 8.9.3 and Theorem 8.9.5 from the new height: Definition 8.1.1, Proposition 8.1.2, Example (A Rotation Has No Invariant Lines), Theorem 8.2.1, Theorem 8.2.4, Theorem 8.2.2, Theorem 8.4.1, Theorem 8.5.1, Theorem 8.8.1, Theorem 8.8.2, Corollary 8.8.3, Lemma 8.9.2, Theorem 8.9.1, Theorem 8.9.3, Theorem 8.9.5.
- **Chapter 9** — three separate debts. The cyclic subspace machinery of §05 is what §03 needs to prove that a semisimple operator is one whose generated algebra acts semisimply; the Weyr commutant is re-read in §05 and again in §10 as the case where the double commutant theorem has nothing to say; and the Smith normal form is what §09 points at for the gap it cannot close: Definition 9.5.2, Proposition 9.5.1, Theorem 9.5.2, Theorem 9.5.3, Proposition 9.4.6, Theorem 9.7.3, Exercise (C1: The same algorithm over the integers) (pointed at, not used), Definition 9.8.1, Proposition 9.8.2.
- **Chapter 10** — the inner product, in three places and never as a standing assumption: §04's proposition that an adjoint-closed algebra acts semisimply, §08's inner product on class functions, and §09's proof that the character matrix is unitary: Definition 10.1.1, Theorem 10.1.4, Definition 10.3.1, Theorem 10.3.2, Definition 10.6.1, Theorem 10.6.1, Theorem 10.7.3.
- **Chapter 11** — the chapter this one explains. Section 9's circulants, the Fourier matrix, the convolution theorem and the diagonalization of every circulant at once are §09's subject; §07's commuting normal families and §10's disjoint-spectra commutant are re-read in §§04 and 10: Corollary 11.4.5, Theorem 11.7.1, Definition 11.9.1, Corollary 11.9.5, Theorem 11.9.1, Theorem 11.9.4, Theorem 11.9.6, Theorem 11.9.3, Theorem 11.9.2, Example (The Fourier matrix of size four), Example (The running example, diagonalized), Corollary 11.10.4.
- **Chapter 13 §12** — the definition of an algebra, which this chapter uses as it stands, and the quaternions, which are the chapter's only non-commutative division algebra and are named as such twice: Definition 13.12.1, Definition 13.12.3.
- **Chapter 14** — the free vector space on a set, which is what the group algebra is built from; the fact that a multilinear map may be prescribed freely on bases, which is how the group algebra's multiplication is shown to exist and be unique; and the two-sided ideal and quotient algebra of §10, which §02 takes over without reproving: Theorem 14.1.1, Definition 14.2.3, Lemma 14.2.2, Definition 14.10.3, Lemma 14.10.5.

22.0.4 Roadmap

- **Associative Algebras.** The vocabulary, and the two examples the rest of the chapter runs on. Subalgebra, with the identity demanded by name and a set exhibited that satisfies every other clause without being one; homomorphism, kernel and image, with transposition as the non-example that reverses products; the subalgebra generated by a set, which for one operator is $F[T]$ of dimension $\deg m_T$. Then the group algebra $F[G]$, built as the free vector space on G with the multiplication forced by bilinearity, and commutative exactly when G is abelian. Cayley's theorem for algebras: left multiplication embeds any finite-dimensional algebra in the operators on itself, so matrices are the general case and not a special one. Finally commutants, three of them computed by comparing entries, and the proof over every field that the center of $M_n(F)$ is the scalars.
- **Ideals and Quotients.** In a non-commutative algebra there are three kinds of ideal, and

which kind is meant decides every later statement. One product rule does the work — sandwiching a matrix between two matrix units extracts one entry and puts it anywhere — and out of it comes the chapter's first real theorem: over **every** field, $M_n(F)$ has no two-sided ideals but $\{0\}$ and itself. The left ideals are another matter, and they are classified completely, by subspaces of row vectors, with the column ideals minimal among them and the transposed statement for right ideals recorded so the two are not confused. Then quotient algebras and the first isomorphism theorem, with two instances: the group algebra of a cyclic group is $F[x]$ with one relation, and the upper triangular 2×2 matrices modulo their strictly upper part are $F \times F$.

- **Simple and Semisimple Algebras.** A second sense in which something cannot be broken apart — this time a space rather than an algebra — and the section opens by warning that both are spelled "simple". Representation of an algebra, invariant subspace, irreducible space. Then the theorem, over any field: every invariant subspace has an invariant complement if and only if the space is a sum of irreducibles, if and only if it is a direct sum of finitely many. An algebra semisimple in its own regular representation acts semisimply on every space. The radical collects what no irreducible representation can see; a nilpotent ideal always lies inside it, a semisimple algebra has none, and the upper triangular matrices have a one-dimensional one, computed. Finally the reconciliation with Chapter 9: an operator is semisimple exactly when $F[T]$ acts semisimply — proved with no hypothesis on the field, because the argument never leaves F.
- **Schur's Lemma.** Maps that respect the action, and how few of them there are. Part (a), that a map between irreducibles is zero or an isomorphism, needs nothing of the field and says the commutant of an irreducible action is a division algebra. Part (b), that over an algebraically closed field the division algebra is F, needs an eigenvalue and nothing else. The failure over $\mathbb{R}$ is then exhibited in full, the commutant of the rotation representation computed by multiplying out and identified with $\mathbb{C}$, every non-zero element invertible exactly as part (a) predicts. Two corollaries: an operator commuting with an irreducible family is a scalar, and an irreducible space for a commutative algebra is a line. Then the look back — Chapter 8 §09's common eigenvector was this, its clever trick Schur's lemma unnamed — and a proposition that an adjoint-closed algebra acts semisimply, which recovers Chapter 11 §07 for commuting self-adjoint families out of two general facts. A warning closes it: "the commutant is the scalars" follows from irreducibility and is never a test for it.
- **Burnside and the Double Commutant.** Two theorems about how much of an algebra its commutant records. Burnside: over an algebraically closed field, a subalgebra of $\mathrm{End}(V)$ containing the identity and acting irreducibly is **all** of $\mathrm{End}(V)$ — irreducibility, a statement about subspaces, forces the largest dimension there is. The proof takes a member of least rank, shows that rank is one, and spreads one rank-one operator over the whole space in two directions; a version for a multiplicative set rather than an algebra is recorded alongside it. The double commutant theorem: if A acts semisimply and contains id_V then $A'' = A$, over **any** field. Its engine is matching a single vector, and the upgrade to a whole basis is done by copying the space n times. Both hypotheses are shown necessary and neither is shown necessary in the converse direction. The section ends by re-reading Chapter 9's Weyr commutant and Chapter 11's disjoint-spectra commutant as computations of A', and by doing the two extremes, the diagonal matrices and the scalars.
- **The Structure Theorem.** Products of algebras, and the observation that such a product has dimension $\sum n_i^2$. The regular representation, whose invariant subspaces are the left ideals. Then Wedderburn in the case the book can carry: over an algebraically closed field a non-zero semisimple algebra is a product $M_{n_1}(F) \times \cdots \times M_{n_k}(F)$, and k and the multiset of the n_i are determined, being the number of isomorphism classes of irreducible spaces and their dimensions. The proof splits the regular representation, keeps one representative

of each class, computes the commutant of the image with Schur's lemma, and lets the double commutant theorem close the gap; Burnside is **not** used. The corollary reads off $\dim A = \sum n_i^2$ and $\dim Z(A) = k$, which between them pin down the block sizes of a small algebra by arithmetic alone. The general theorem over a division ring and Wedderburn's little theorem get their own subsection, stated with credit and proved nowhere. Two decompositions are computed: $\mathbb{C}[C_4]$ with its four idempotents, and $M_2(\mathbb{C})$, already in Wedderburn form.

- **Group Representations.** A homomorphism $G \to \mathrm{GL}(V)$, with the trivial, sign, permutation, rotation and regular representations, and a non-example that fails only by not being well defined on a quotient. Subrepresentations, equivalence, irreducibility, direct sums. Then the bridge: representations of G over F correspond exactly to algebra homomorphisms $F[G] \to \mathrm{End}(V)$, carrying invariant subspaces to invariant subspaces and intertwining maps to $F[G]$-maps, so §§01 to 06 apply verbatim. Maschke's theorem: average a projection over the group and the average is a projection onto the same subspace that commutes with the action. The hypothesis $\mathrm{char}\, F \nmid |G|$ is spent on one division, and without it the unnormalized sum annihilates the subspace instead of fixing it; $\mathbb{Z}/p\mathbb{Z}$ on $\mathbb{F}_p^2$ is worked out, and a warning drops finiteness instead and breaks the theorem the other way. Complete reducibility follows by induction, so $F[G]$ is semisimple. The section closes with the two families §08 will compute characters for: all the irreducible complex representations of $\mathbb{Z}/n\mathbb{Z}$, and three for S_3 with every matrix written out.
- **Characters and Orthogonality.** Conjugacy classes are built here, since the book has not met them, and shown to partition the group. A character is one number per group element: constant on classes, additive over direct sums, equal to the dimension at the identity and largest there in absolute value, conjugated by inversion — and **not** a homomorphism. The class functions form an inner product space whose dimension is the number of classes. Two averaging lemmas — the average of a representation is the projection onto the fixed space, and the trace of $f \mapsto BfA$ is $(\mathrm{tr}\, A)(\mathrm{tr}\, B)$ — combine into a count of intertwining maps, and Schur's lemma turns that count into a 0 or a 1: the irreducible characters are orthonormal. The criterion $\langle \chi, \chi \rangle = 1$ then decides irreducibility without looking at a vector, and decomposes the permutation representation of S_3 in three lines. The deepest result is that the characters **span** the class functions, by a third averaging argument run on the regular representation; so the number of irreducible representations is the number of conjugacy classes. Out of it come the sum of the squares of the degrees — the identity §06 proved by another route entirely — and column orthogonality, from a one-sided inverse. The tables of S_3 and $\mathbb{Z}/4\mathbb{Z}$ are computed and every relation checked.
- **Finite Abelian Groups and the Fourier Transform.** The order of an element, the cyclic group and the direct product of groups are built first, Chapter 0 having none of them. Over $\mathbb{C}$ an abelian group has only one-dimensional representations, so a character is a homomorphism $G \to \mathbb{C}^\times$ whose values are roots of unity, and the characters form a group $\widehat{G}$ under pointwise multiplication. It has the same order as G, always; it is isomorphic to G for cyclic groups and for products of them, and the section stops there and says exactly what it is not proving. Lining G up against $\widehat{G}$ gives a square character matrix, which is unitary, and inversion and Plancherel are what a unitary matrix always gives. Then the three identifications: for $\mathbb{Z}/n\mathbb{Z}$ the character matrix **is** the Fourier matrix; the group algebra of any finite abelian group splits into the functions on $\widehat{G}$, which for the cyclic group is the convolution theorem; and the circulants are the group algebra of $\mathbb{Z}/n\mathbb{Z}$ acting by multiplication, with the basis reversal that Chapter 11's indexing forces spelled out in a warning. The case $n = 4$ is checked against Chapter 11's numbers.
- **What the Chapter Buys.** A closing section that introduces nothing. Four moves are named and located; four earlier theorems are read again from here — simultaneous diagonalization, commuting normal families, circulants and the discrete Fourier transform,

and the two commutant computations of Chapters 9 and 11. A table gives, for each main theorem, the hypothesis on the field it needs and the counterexample that shows the hypothesis is not decoration, with three comments on what the table reveals. Then the list of what was quoted, the list of what was left outside and why, and a last look back at what a clean answer cost.

22.0.5 Named moves

- **Average over the group to build an invariant object.** Start with something that depends on a choice — a projection, an arbitrary linear map, a vector — and replace it by the average of its translates. The average is invariant because translating permutes the summands. This is the whole of Maschke's theorem, the whole of the orthogonality relations, and the whole of the proof that the characters span. It costs one division by $|G|$, and that division is the chapter's only hypothesis on the characteristic.
- **Use Schur's lemma to force a scalar, then take a trace to find which one.** Build an operator by some construction, check that it commutes with everything in sight, conclude it is λ id, and compute λ from the trace. Two lines that replace an unknown operator by a number, over and over, and the exact price is that F be algebraically closed.
- **Sandwich with matrix units.** The identity $\mathbf{E}_{ij}\mathbf{X}\mathbf{E}_{kl} = x_{jk}\mathbf{E}_{il}$ extracts one entry of an arbitrary matrix and puts it wherever you like. An ideal that contains anything non-zero therefore contains every matrix unit, which is the simplicity of $M_n(F)$ in three lines and over any field.
- **Let the algebra act on itself.** An abstract algebra has no vectors until you give it some, and the cheapest supply is the algebra. Left multiplication makes it an algebra of operators (which is why matrices are general), and the invariant subspaces of that action are the left ideals — so a question about ideals and a question about representations are one question.
- **Copy the space to upgrade one vector to a basis.** A density argument that matches an operator on a single vector becomes a proof that two operators are equal, once it is run on $V \oplus \cdots \oplus V$ with the basis of V packed into one vector of the copy. The only work is checking that the copied algebra inherits the hypotheses, and semisimplicity is the hypothesis that survives copying.
- **Count with $\sum n_i^2$.** The dimension identity of the structure theorem, read for a group algebra as $|G| = \sum_i (\dim V_i)^2$, pins down the degrees of all the irreducible representations of a small group from the number of conjugacy classes alone, before a single matrix is written. It does for this chapter what Rank–Nullity does for Chapter 3.
- **Read a family of operators as the algebra it generates.** A commuting family generates a commutative algebra; a group of invertible operators spans one; a single operator generates $F[T]$. Invariant subspaces, commutants and irreducibility are unchanged by the passage, so a theorem about algebras is a theorem about every family the book has studied. That is what lets the last section re-prove four earlier results without a new idea in any of them.

22.1 Associative Algebras

Since Chapter 8 the book has looked at one operator at a time, or at a family whose members commute. But operators rarely arrive alone. The polynomials in a fixed operator, the circulants of Chapter 11 §09, the matrices commuting with a given matrix, the linear symmetries of a

figure: each of these is a whole set of operators, closed under addition, under scalars, and under composition. This section makes such a system a single object of study. It fixes the vocabulary — subalgebra, homomorphism, generated algebra, commutant — and builds the two examples the rest of the chapter runs on, the matrix algebra and the group algebra.

22.1.1 What an algebra is, and what we assume about it

The definition is already in the book. Chapter 13 §12 introduced an **algebra over** F (Definition 13.12.1) as a vector space A over F with a multiplication $A \times A \to A$ that is bilinear (A1), associative (A2) and has an identity 1_A (A3). It also fixed the notion of a homomorphism of F-algebras. We build on that definition; the homomorphism clause is restated below only so that later sections have a label to cite.

Three standing conventions, stated once and used everywhere in this chapter.

- **Associative and unital.** Every algebra satisfies (A1), (A2) and (A3). Lie algebras and the cross product, which fail (A2) and (A3), are outside the chapter.
- **Finite-dimensional.** Unless a statement says otherwise, $\dim_F A < \infty$. The one standing exception is $F[x]$, which we keep as a source of counterexamples and always name as infinite-dimensional when we use it that way.
- **Not commutative, not invertible.** Nothing requires $xy = yx$, and nothing requires a non-zero element to have an inverse. An algebra has an addition and a multiplication with all the usual laws except commutativity and division; it is not a group.

The examples are the ones Chapter 13 listed, and it is worth seeing why each satisfies the axioms. In $M_n(F)$, matrix multiplication is bilinear and associative with identity $\mathbf{I}_n$ (Theorem 0.9.4), so $M_n(F)$ is an F-algebra of dimension n^2. In $\mathcal{L}(V)$ for a vector space V over F, composition is bilinear, associative and has the identity id_V (Theorem 3.4.2), so $\mathcal{L}(V)$ is an F-algebra; when $\dim V = n$ it has dimension n^2 (Theorem 3.6.4). The polynomial ring $F[x]$ is an algebra of infinite dimension. The quaternions $\mathbb{H}$ form a real algebra of dimension 4 (Definition 13.12.3). The field F itself is an algebra of dimension 1, the degenerate case, and it matters: it is the smallest algebra that is not the zero space, and every non-zero algebra contains a copy of it.

> *Remark.* Many books write $\mathrm{End}(V)$, for the **endomorphisms** of V, where this book writes $\mathcal{L}(V)$, and $\mathrm{Hom}(V, W)$ where this book writes $\mathcal{L}(V, W)$. The names mean the same objects. This book writes $\mathcal{L}$ by default, and later sections of this chapter write $\mathrm{End}(V)$ when the algebra structure is the point.

22.1.2 Subalgebras

After an object come its subobjects. We already know several sets of matrices that are closed under the three operations: the diagonal matrices, the upper triangular matrices, the circulants (Corollary 11.9.5), the polynomials in a fixed matrix. In each case we checked closure by hand. The right move is to name the condition once.

A subalgebra is a subspace that is closed under multiplication and contains the identity.

Definition 22.1.1 — Subalgebra

Let A be an algebra over F. A subset $B \subseteq A$ is a **subalgebra** of A if

(SA1) B is a **subspace** of A;
(SA2) $xy \in B$ **for all** $x, y \in B$;
(SA3) $1_A \in B$.

Clause by clause. (SA1) is the linear condition: B is closed under addition and under scalars, so it is a vector space in its own right. (SA2) says the multiplication of A restricts to a map $B \times B \to B$. (SA3) asks for **the** identity of A, not merely for some element of B that acts as an identity on B; the difference is real, and the warning below shows a set that satisfies (SA1) and (SA2), has its own identity, and is not a subalgebra.

Well-definedness. A subalgebra is an algebra. Bilinearity, associativity and the identity law are equations among elements of B, and they hold there because they hold in A. So nothing needs to be re-checked once (SA1)–(SA3) are known — which is exactly the labor that naming the condition saves.

Throughout, $\mathbf{E}_{ij}$ denotes the **matrix unit** with a 1 in position (i, j) and zeros elsewhere; the n^2 of them are a basis of $M_n(F)$ (Example (Standard Bases)).

Example. (Six subalgebras)

Decide which of the following are subalgebras, and of which algebra.

(a) The scalars $F1_A = \{c1_A : c \in F\}$ inside any algebra A.
(b) The diagonal matrices and the upper triangular matrices inside $M_n(F)$. We write $\mathcal{T}_n$ for the second of these, since it returns below and in the next section.
(c) The circulants $\mathcal{C}_n$ inside $M_n(\mathbb{C})$ (Chapter 11 §09).
(d) The quaternions $\mathbb{H}$ inside $M_2(\mathbb{C})$, as an algebra over $\mathbb{R}$.
(e) The **strictly** upper triangular matrices inside $M_n(F)$.
(f) The matrices of trace 0 inside $M_2(F)$.

Solution.

(a) A subalgebra. It is the image of the linear map $c \mapsto c1_A$, hence a subspace; $(c1_A)(d1_A) = (cd)1_A$ by bilinearity; and $1_A = 1 \cdot 1_A$. Its dimension is 1 unless $A = \{0\}$: if $1_A = 0$, then $x = 1_A x = 0$ for every x. This is the degenerate example, and every subalgebra contains it.
(b) Both are subalgebras. Sums and scalar multiples of diagonal (respectively upper triangular) matrices are again such, the product of two upper triangular matrices is upper triangular because $(\mathbf{AB})_{ij} = \sum_k a_{ik}b_{kj}$ vanishes when $i > j$ — every term has $k < i$ or $k > j$ — and $\mathbf{I}_n$ is diagonal. The diagonal matrices have dimension n, with basis the $\mathbf{E}_{ii}$, and $\mathcal{T}_n$ has dimension $n(n+1)/2$, with basis the $\mathbf{E}_{ij}$ for $i \leq j$.
(c) A subalgebra, of dimension n: this is exactly Corollary 11.9.5 (a), (b), together with the fact that $\mathbf{I}$ is the circulant whose first row is $(1, 0, \ldots, 0)$.
(d) A subalgebra of $M_2(\mathbb{C})$ **over** $\mathbb{R}$, of real dimension 4, as Definition 13.12.3 records:

the real span of $\mathbf{I}_2, \mathbf{i}, \mathbf{j}, \mathbf{k}$ is closed under multiplication by the quaternion relations, and it contains $\mathbf{I}_2$. It is **not** a subalgebra over $\mathbb{C}$, since it is not closed under multiplication by i: $i\mathbf{I}_2$ has both diagonal entries equal to i, while every element of $\mathbb{H}$ has diagonal entries $a+bi$ and $a-bi$, forcing $a=0$ and $b=1$ and $b=-1$ at once.

(e) **Not** a subalgebra. It is a subspace and it is closed under products, by the computation in (b) with strict inequalities. But $\mathbf{I}_n$ is not strictly upper triangular for $n \geq 1$, so (SA3) fails. This is the non-example by minimal change: drop the diagonal from (b) and exactly one clause breaks.

(f) **Not** a subalgebra. $\mathbf{E}_{12}\mathbf{E}_{21} = \mathbf{E}_{11}$ has trace $1 \neq 0$, so (SA2) fails. Clause (SA3) fails too, except in characteristic 2, where $\operatorname{tr} \mathbf{I}_2 = 2 = 0$.

Warning. (SA3) is not a formality. In $M_2(F)$, the set $B = \{a\mathbf{E}_{11} : a \in F\}$ is a subspace, is closed under products, and even has an identity of its own, namely $\mathbf{E}_{11}$, since $\mathbf{E}_{11}(a\mathbf{E}_{11}) = a\mathbf{E}_{11}$. It is still not a subalgebra of $M_2(F)$, because $\mathbf{I}_2 \notin B$. Subspaces that are closed under multiplication but miss the identity are the shape of the *ideals* of the next section — though this particular one is not an ideal either, as Section 2 checks. They are a different kind of object, and no theorem about subalgebras applies to them.

Quick check. In $M_2(\mathbb{F}_2)$, is the set of matrices of trace 0 closed under multiplication? Does it contain the identity?

Solution. It contains $\mathbf{I}_2$, because $\operatorname{tr} \mathbf{I}_2 = 1+1 = 0$ in $\mathbb{F}_2$, so (SA3) holds here. But it is still not a subalgebra: $\mathbf{E}_{12}$ and $\mathbf{E}_{21}$ have trace 0 and $\mathbf{E}_{12}\mathbf{E}_{21} = \mathbf{E}_{11}$ has trace $1 \neq 0$, so (SA2) fails. One clause can hold over one field and fail over another; the other clause fails over every field.

22.1.3 Homomorphisms, isomorphisms, and the algebra generated by a set

Definition 13.12.1 already says what a homomorphism of F-algebras is: an F-linear map $\varphi\colon A \to B$ with $\varphi(xy) = \varphi(x)\varphi(y)$ and $\varphi(1_A) = 1_B$. We name it, so that later sections can cite it, and add the two subsets it produces.

Definition 22.1.2 — Algebra Homomorphism, Kernel and Image

Let A and B be algebras over F. An **algebra homomorphism** $\varphi\colon A \to B$ is an F-linear map with

$$\varphi(xy) = \varphi(x)\varphi(y) \quad \text{for all } x, y \in A, \qquad \varphi(1_A) = 1_B,$$

as in Definition 13.12.1. Its **kernel** is $\ker \varphi = \{x \in A : \varphi(x) = 0\}$ and its **image** is $\operatorname{im} \varphi = \{\varphi(x) : x \in A\}$, the kernel and image of φ as a linear map.

The unital clause $\varphi(1_A) = 1_B$ does not follow from the other two. The zero map $M_2(F) \to M_2(F)$ is linear and multiplicative and sends $\mathbf{I}_2$ to $0 \neq \mathbf{I}_2$, so it is **not** an algebra homomorphism. We will never call it one.

Definition 22.1.3 — Isomorphic Algebras

An **algebra isomorphism** is a bijective algebra homomorphism. Algebras A and B are **isomorphic**, written $A \cong B$, if there is an algebra isomorphism $A \to B$.

The inverse of an algebra isomorphism φ is again one: it is linear (Theorem 3.5.1), it satisfies $\varphi^{-1}(uv) = \varphi^{-1}(u)\varphi^{-1}(v)$ — apply the injective map φ to both sides — and $\varphi^{-1}(1_B) = 1_A$. So $\cong$ is symmetric, and it is reflexive and transitive for the same reasons as in Theorem 3.5.3.

Two homomorphisms to keep in mind. First, taking matrices: for a finite-dimensional V with ordered basis $\mathcal{B}$, the map $T \mapsto [T]_{\mathcal{B}}^{\mathcal{B}}$ is an algebra isomorphism $\mathcal{L}(V) \to M_n(F)$, being a linear bijection (Theorem 3.6.4) that turns composition into matrix multiplication (Theorem 3.6.2) and sends id_V to $\mathbf{I}_n$. Second, a non-example: transposition $\mathbf{A} \mapsto \mathbf{A}^\top$ on $M_n(F)$ is a linear bijection fixing $\mathbf{I}_n$, but $(\mathbf{AB})^\top = \mathbf{B}^\top\mathbf{A}^\top$, so it reverses products. For $n \geq 2$ it is not a homomorphism, since $(\mathbf{E}_{12}\mathbf{E}_{21})^\top = \mathbf{E}_{11}$ while $\mathbf{E}_{12}^\top\mathbf{E}_{21}^\top = \mathbf{E}_{21}\mathbf{E}_{12} = \mathbf{E}_{22}$.

Now the construction we need constantly: the smallest subalgebra containing a given set of operators.

Definition 22.1.4 — The Subalgebra Generated by a Set

Let A be an algebra over F and $S \subseteq A$. The **subalgebra generated by** S, written $F\langle S\rangle$, is the intersection of all subalgebras of A containing S.

The letter F in $F\langle S\rangle$ records that scalars are allowed; the next section writes $\langle S\rangle$, without the F, for the **ideal** generated by S, which is a different and usually larger set. The intersection of any collection of subalgebras is a subalgebra — each clause of Definition 22.1.1 is preserved by intersections — and A itself is one of them, so $F\langle S\rangle$ is a subalgebra containing S, and it is contained in every other one. That is what "generated" means. It also has a concrete description.

Proposition 22.1.1 — What the Generated Subalgebra Contains

Let A be an algebra over F and $S \subseteq A$. Then $F\langle S\rangle$ is the span of 1_A together with all finite products $s_1 s_2 \cdots s_k$ with $k \geq 1$ and $s_1, \ldots, s_k \in S$.

Proof. Let P be that span. Every subalgebra containing S contains each product $s_1 \cdots s_k$ by (SA2) and induction on k, contains 1_A by (SA3), and is a subspace by (SA1); hence it contains P. In particular $P \subseteq F\langle S\rangle$.

Conversely P is itself a subalgebra: it is a span, hence a subspace; it contains 1_A; and a product of two spanning elements is either 1_A, or a product $s_1 \cdots s_k$, or a concatenation $(s_1 \cdots s_k)(t_1 \cdots t_l)$, which is again such a product by associativity. By bilinearity, a product of two elements of P is a combination of such products, so it lies in P. Since $S \subseteq P$, minimality gives $F\langle S\rangle \subseteq P$. This proves the proposition.

■

For a single operator the products are just the powers, and the minimal polynomial says how

many of them are independent.

Proposition 22.1.2 — The Algebra Generated by One Operator

Let $V \neq \{\mathbf{0}\}$ be finite-dimensional over F and let $T \in \mathcal{L}(V)$ have minimal polynomial m_T, of degree d. Then

$$F[T] := \{p(T) : p \in F[x]\}$$

is a **commutative** subalgebra of $\mathcal{L}(V)$, it equals $F\langle\{T\}\rangle$, and $(\mathrm{id}_V, T, T^2, \dots, T^{d-1})$ is a basis of it. In particular $\dim F[T] = \deg m_T$.

Idea. Division with remainder cuts every power of T down to degree less than d, which gives spanning; and a shorter relation among the powers would be an annihilating polynomial of degree less than d, which is what minimality forbids.

Proof. By Theorem 5.7.1 the map $p \mapsto p(T)$ is linear and multiplicative, so $F[T]$ is a subspace closed under products, and it contains $\mathrm{id}_V = 1(T)$; it is therefore a subalgebra. Any two of its elements commute, since $p(T)q(T) = (pq)(T) = (qp)(T) = q(T)p(T)$. By Proposition 22.1.1, $F\langle\{T\}\rangle$ is the span of id_V and the powers T^k with $k \geq 1$, which is $F[T]$.

Since V is finite-dimensional, m_T exists (Theorem 5.7.3 (b), (c)); and $d \geq 1$, because the only monic polynomial of degree 0 is 1, whose value at T is $\mathrm{id}_V \neq 0$ since $V \neq \{\mathbf{0}\}$.

Spanning. Let $p \in F[x]$. Dividing by m_T (Theorem 5.1.1) gives $p = qm_T + r$ with $\deg r < d$, and $p(T) = q(T)m_T(T) + r(T) = r(T)$, a combination of $\mathrm{id}_V, T, \dots, T^{d-1}$.

Independence. Suppose $c_0\,\mathrm{id}_V + c_1T + \cdots + c_{d-1}T^{d-1} = 0$ with the c_i not all zero. Then $r = c_0 + c_1x + \cdots + c_{d-1}x^{d-1}$ is a non-zero polynomial with $r(T) = 0$ and $\deg r < d$, contradicting the fact that m_T has least degree among the non-zero annihilating polynomials (Theorem 5.7.3 (b)).

So the d listed operators are a basis, and $\dim F[T] = d$. This proves the proposition.

■

Example. (Two polynomial algebras)

Compute $\dim F[\mathbf{A}]$ for $\mathbf{A} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$ and for $\mathbf{B} = \mathrm{diag}(1, 2, 3)$ over $\mathbb{Q}$.

Solution. For $\mathbf{A}$: $\mathbf{A}^2 = 0$ and $\mathbf{A} \neq 0$, so x^2 annihilates $\mathbf{A}$ and no polynomial of degree 1 does (if $a\mathbf{I} + b\mathbf{A} = 0$, reading the $(1,1)$ and $(1,2)$ entries gives $a = b = 0$). Hence $m_{\mathbf{A}} = x^2$ and $\dim \mathbb{Q}[\mathbf{A}] = 2$, with basis $(\mathbf{I}, \mathbf{A})$. Note that $\dim \mathbb{Q}[\mathbf{A}] = 2$ is much smaller than $\dim M_3(\mathbb{Q}) = 9$.

For $\mathbf{B}$: $(x-1)(x-2)(x-3)$ annihilates $\mathbf{B}$, since the product of the three diagonal matrices $\mathbf{B} - k\mathbf{I}$ is 0. No polynomial r of degree at most 2 does, unless $r = 0$: $r(\mathbf{B}) = \mathrm{diag}(r(1), r(2), r(3)) = 0$ would give r three distinct roots. So $m_{\mathbf{B}}$ has degree 3 and $\dim \mathbb{Q}[\mathbf{B}] = 3$, with basis $(\mathbf{I}, \mathbf{B}, \mathbf{B}^2)$.

22.1.4 The group algebra

Here is the object that turns a group of symmetries into linear algebra. Suppose a finite group G acts on a space by invertible operators $\rho(g)$. Then every F-combination $\sum_g a_g \rho(g)$ is again an operator, and the products of such combinations are governed entirely by the multiplication table of G. It is worth building, once and for all, the algebra in which those formal combinations live.

The group algebra is the set of formal F-combinations of group elements, multiplied by the group law.

Definition 22.1.5 — Group Algebra

Let G be a **finite** group with identity e, and let F be a field. The **group algebra** $F[G]$ is the free vector space $F^{(G)}$ on the set G (Definition 14.2.3), with basis $\{\delta_g : g \in G\}$, equipped with the unique bilinear multiplication satisfying

$$\delta_g \, \delta_h = \delta_{gh} \qquad \text{for all } g, h \in G.$$

We write g for δ_g and 1 for δ_e, so that a general element is a formal sum $\sum_{g \in G} a_g \, g$ with all $a_g \in F$, two such sums are equal exactly when all their coefficients agree, and

$$\Big(\sum_g a_g \, g\Big)\Big(\sum_h b_h \, h\Big) = \sum_{k \in G} \Big(\sum_{g \in G} a_g \, b_{g^{-1}k}\Big) k.$$

Well-definedness. Choose an ordering $g_1, \dots, g_N$ of G, so that $(\delta_{g_1}, \dots, \delta_{g_N})$ is an ordered basis of $F^{(G)}$ (Lemma 14.2.2 (a)). By Theorem 14.1.1 with $k = 2$, there is **exactly one** bilinear map $F[G] \times F[G] \to F[G]$ taking the prescribed values $\delta_{g_i g_j}$ on basis pairs. The displayed formula for the product is that bilinear map written out: expanding $\sum_{g,h} a_g b_h \, gh$ and collecting the terms with $gh = k$, which means $h = g^{-1}k$, gives the stated coefficient of k.

The axioms hold. Bilinearity is (A1) by construction. For associativity (A2), both $(xy)z$ and $x(yz)$ are trilinear in (x, y, z), so by Theorem 14.1.1 it is enough to compare them on basis triples, where $(\delta_g \delta_h)\delta_k = \delta_{(gh)k} = \delta_{g(hk)} = \delta_g(\delta_h \delta_k)$ by the associativity axiom (G1) of Definition 0.10.1. For (A3), $\delta_e \delta_g = \delta_{eg} = \delta_g = \delta_g \delta_e$ on basis elements, hence everywhere by bilinearity. So $F[G]$ is an F-algebra, of dimension $|G|$.

In words: an element of $F[G]$ is a bookkeeping device, a list of $|G|$ scalars indexed by the group, and multiplying two of them convolves the lists along the group law. The group sits inside $F[G]$: the map $g \mapsto \delta_g$ is injective (distinct basis vectors) and multiplicative, and each δ_g is invertible with inverse $\delta_{g^{-1}}$.

Example. (Three group algebras)

(a) $G = \{e\}$.
(b) $G = \mathbb{Z}/n\mathbb{Z}$, written multiplicatively as $\{1, g, \dots, g^{n-1}\}$ with $g^n = 1$.
(c) $G = S_3$.

In each case give the dimension and decide whether $F[G]$ is commutative.

Solution.

(a) $F[\{e\}] = F\delta_e \cong F$, of dimension 1, and commutative. This is the degenerate case.

(b) $\dim F[G] = n$, and $F[G]$ is commutative because $g^i g^j = g^{i+j} = g^j g^i$ on basis elements and multiplication is bilinear. Moreover the map $\varepsilon\colon F[x] \to F[G]$ sending $p = \sum_i c_i x^i$ to $\sum_i c_i g^i$ is an algebra homomorphism: it is linear by construction, it sends 1 to $g^0 = 1$, and for $p = \sum_i c_i x^i$ and $q = \sum_j d_j x^j$,

$$\varepsilon(pq) = \sum_k \Big(\sum_{i+j=k} c_i d_j \Big) g^k = \Big(\sum_i c_i g^i \Big) \Big(\sum_j d_j g^j \Big) = \varepsilon(p)\varepsilon(q),$$

where the middle equality is bilinearity together with $g^i g^j = g^{i+j}$. It is surjective because the powers $1, g, \dots, g^{n-1}$ are a basis. Its kernel is exactly $\langle x^n - 1 \rangle$: dividing p by $x^n - 1$ (Theorem 5.1.1) gives $p = q(x^n - 1) + r$ with $\deg r < n$, and since $\varepsilon(x^n - 1) = g^n - 1 = 0$ we get $\varepsilon(p) = \varepsilon(r)$, which vanishes only when all coefficients of r vanish, the g^i being a basis. The next section turns this into an isomorphism $F[\mathbb{Z}/n\mathbb{Z}] \cong F[x]/\langle x^n - 1 \rangle$.

(c) $\dim F[S_3] = 6$, and $F[S_3]$ is **not** commutative: with $\sigma = (1\ 2)$ and $\tau = (1\ 2\ 3)$ we have $\sigma\tau \neq \tau\sigma$ in S_3, so $\delta_\sigma \delta_\tau \neq \delta_\tau \delta_\sigma$ are distinct basis vectors. In general $F[G]$ is commutative if and only if G is abelian: the displayed argument gives one direction, and if $F[G]$ is commutative then $\delta_{gh} = \delta_g \delta_h = \delta_h \delta_g = \delta_{hg}$, and distinct group elements give distinct basis vectors, so $gh = hg$.

Warning. The elements of $F[G]$ are formal sums, not group elements, and most of them are **not** invertible. In $\mathbb{Q}[\mathbb{Z}/2\mathbb{Z}]$ with $\mathbb{Z}/2\mathbb{Z} = \{1, g\}$, the element $1 + g$ satisfies $(1+g)^2 = 1 + 2g + g^2 = 2(1+g)$, so $\frac{1}{2}(1+g)$ is a non-zero element equal to its own square and different from 1. Multiplying it by $1 - g$ gives 0, so neither factor has an inverse. Passing from G to $F[G]$ buys linearity at the price of invertibility.

22.1.5 Every finite-dimensional algebra is an algebra of matrices

Matrices look like a special case of an algebra. They are not: every finite-dimensional algebra is one, and the embedding is the most economical thing imaginable — let the algebra act on itself.

Theorem 22.1.3 — Left Multiplication Embeds an Algebra in Its Own Operators

Let A be an algebra over F. For $a \in A$ define $L_a\colon A \to A$ by $L_a(x) = ax$. Then

$$L\colon A \to \mathcal{L}(A), \qquad a \mapsto L_a,$$

is an **injective** algebra homomorphism. If $\dim_F A = n < \infty$, then A is isomorphic to a subalgebra of $M_n(F)$.

Idea. Each axiom of an algebra says one thing about L: bilinearity in the second slot makes L_a linear, bilinearity in the first makes $a \mapsto L_a$ linear, associativity makes L multiplicative, and the identity makes L unital and — this is the point — injective,

because an operator that kills everything in particular kills 1_A, and $L_a(1_A) = a$.

Proof. Each L_a is linear, because multiplication is linear in its second argument (A1). The map L is linear, because multiplication is linear in its first argument: $L_{a+ca'}(x) = (a + ca')x = ax + c(a'x)$ for all x.

L is multiplicative: for $a, b, x \in A$, associativity (A2) gives

$$L_{ab}(x) = (ab)x = a(bx) = L_a\big(L_b(x)\big) = (L_aL_b)(x),$$

so $L_{ab} = L_aL_b$. It is unital: $L_{1_A}(x) = 1_Ax = x$, so $L_{1_A} = \mathrm{id}_A$.

L is injective: if $L_a = 0$ then, evaluating at 1_A, $a = a1_A = L_a(1_A) = 0$. So $\ker L = \{0\}$ and L is injective (Theorem 3.2.3).

Suppose now $\dim_F A = n < \infty$. Then $\operatorname{im} L$ is a subalgebra of $\mathcal{L}(A)$: it is a subspace, it is closed under products since $L_aL_b = L_{ab}$, and it contains $\mathrm{id}_A = L_{1_A}$. The map $L\colon A \to \operatorname{im} L$ is a bijective algebra homomorphism, hence an algebra isomorphism. Fixing an ordered basis of A and taking matrices is an algebra isomorphism $\mathcal{L}(A) \to M_n(F)$, as recorded after Definition 22.1.3, and it carries $\operatorname{im} L$ to a subalgebra of $M_n(F)$ isomorphic to A. This proves the theorem.

■

The theorem is the reason the rest of the chapter may think in matrices without loss. It is also a genuine computation: to see an abstract algebra concretely, write down the matrices of left multiplication in a basis.

Example. (Left multiplication for the upper triangular algebra)

Let $A = \mathcal{T}_2$, the upper triangular matrices in $M_2(F)$, with ordered basis $\mathcal{B} = (\mathbf{E}_{11}, \mathbf{E}_{12}, \mathbf{E}_{22})$. Compute the matrix of $L_{\mathbf{U}}$ for $\mathbf{U} = \begin{pmatrix} a & b \\ 0 & c \end{pmatrix}$, and read off what the embedding of Theorem 22.1.3 does.

Solution. Multiply each basis element on the left by $\mathbf{U}$:

$$\mathbf{U}\mathbf{E}_{11} = a\mathbf{E}_{11}, \qquad \mathbf{U}\mathbf{E}_{12} = a\mathbf{E}_{12}, \qquad \mathbf{U}\mathbf{E}_{22} = b\mathbf{E}_{12} + c\mathbf{E}_{22}.$$

Putting the coordinate vectors in as columns,

$$[L_{\mathbf{U}}]_{\mathcal{B}}^{\mathcal{B}} = \begin{pmatrix} a & 0 & 0 \\ 0 & a & b \\ 0 & 0 & c \end{pmatrix}.$$

So $\mathcal{T}_2$, an algebra of 2×2 matrices of dimension 3, is isomorphic to the algebra of 3×3 matrices of this shape. The embedding is faithful but wasteful: $\mathbf{U} \mapsto \mathbf{U}$ already embeds $\mathcal{T}_2$ in $M_2(F)$. Left multiplication is the embedding that always exists, not the smallest one.

22.1.6 Commutants

The last construction of the section is the one that will carry Schur's lemma later. Given a set of operators, ask which operators commute with all of them. Chapter 8 §09 asked this about a pair, Chapter 9 §04 about a Weyr matrix, Chapter 11 §07 about a normal family. It is the same question each time.

The commutant of a set is everything that commutes with all of it.

Definition 22.1.6 — Commutant and Center

Let A be an algebra over F and let $S \subseteq A$ be **any subset**. The **commutant** of S in A is

$$S' := \{a \in A : as = sa \text{ for every } s \in S\}.$$

The **center** of A is $Z(A) := A'$, the set of elements commuting with **every** element of A. We write S'' for $(S')'$.

In words: to belong to S', an element must commute with each member of S — one failure disqualifies it. The members of S need not commute with each other, and S need not be a subspace or a subalgebra; the definition asks nothing of S.

Proposition 22.1.4 — Properties of the Commutant

Let A be an algebra over F and $S, T \subseteq A$.

(a) S' is a subalgebra of A; in particular $Z(A)$ is a commutative subalgebra.
(b) If $S \subseteq T$, then $T' \subseteq S'$.
(c) $S \subseteq S''$.
(d) $S' = S'''$.

Proof.

(a) Fix $s \in S$. The set $\{a : as = sa\}$ is the kernel of the linear map $a \mapsto as - sa$, hence a subspace (Theorem 3.2.1); S' is the intersection of these subspaces over $s \in S$, hence a subspace. If $a, b \in S'$ then $(ab)s = a(bs) = a(sb) = (as)b = (sa)b = s(ab)$, using associativity at each step, so $ab \in S'$. And $1_A s = s = s1_A$, so $1_A \in S'$. Thus S' is a subalgebra. For the center, every element of $Z(A)$ commutes with every element of A, so in particular any two of them commute.

(b) If a commutes with every element of T and $S \subseteq T$, then a commutes with every element of S.

(c) Let $s \in S$. Every $a \in S'$ satisfies $as = sa$, which is the condition for s to lie in $(S')'$.

(d) Applying (c) to S' gives $S' \subseteq S'''$. Applying (b) to the inclusion $S \subseteq S''$ of (c) gives $(S'')' \subseteq S'$, that is, $S''' \subseteq S'$.

■

Three commutants, computed. Each is a short exercise in comparing entries, and the pattern they show is the one Schur's lemma will explain.

Example. (Commutants of three matrices)

Compute the commutant S' inside the stated algebra for

(a) $S = \{\mathbf{D}\}$ inside $M_3(F)$, where $\mathbf{D} = \operatorname{diag}(d_1, d_2, d_3)$ has d_1, d_2, d_3 **distinct**;
(b) $S = \{\mathbf{N}\}$ inside $M_3(F)$, where $\mathbf{N} = \mathbf{J}_3(0)$ is the nilpotent Jordan block;
(c) $S = M_3(\mathbb{Q})$ inside $M_3(\mathbb{Q})$.

Solution.

(a) *Distinct diagonal.* Comparing the (i,j) entries, $(\mathbf{DX})_{ij} = d_i x_{ij}$ and $(\mathbf{XD})_{ij} = x_{ij} d_j$, so $\mathbf{DX} = \mathbf{XD}$ says $(d_i - d_j)x_{ij} = 0$ for all i, j. Since the d_i are distinct, $x_{ij} = 0$ whenever $i \neq j$. So $\{\mathbf{D}\}'$ is the algebra of diagonal matrices in $M_3(F)$, of dimension 3. Here $m_{\mathbf{D}}$ has degree 3, since $(x - d_1)(x - d_2)(x - d_3)$ annihilates $\mathbf{D}$ while no non-zero polynomial of degree at most 2 does, such a polynomial having the three distinct roots d_1, d_2, d_3; so by Proposition 22.1.2 $\dim F[\mathbf{D}] = 3$ as well. Every polynomial in $\mathbf{D}$ commutes with $\mathbf{D}$, so $F[\mathbf{D}] \subseteq \{\mathbf{D}\}'$, and equal dimensions give $\{\mathbf{D}\}' = F[\mathbf{D}]$.

(b) *Jordan block.* Write $\mathbf{N} = \mathbf{E}_{12} + \mathbf{E}_{23}$. Then $(\mathbf{NX})_{ij} = x_{i+1,j}$ (read as 0 when $i + 1 > 3$) and $(\mathbf{XN})_{ij} = x_{i,j-1}$ (read as 0 when $j - 1 < 1$). Setting these equal for all i, j: the entries with $j = 1$ give $x_{21} = x_{31} = 0$, the entries with $i = 3$ give $x_{31} = x_{32} = 0$, and the four remaining equations give $x_{22} = x_{11}$, $x_{23} = x_{12}$, $x_{32} = x_{21}$ and $x_{33} = x_{22}$. So

$$\{\mathbf{N}\}' = \left\{ \begin{pmatrix} a & b & c \\ 0 & a & b \\ 0 & 0 & a \end{pmatrix} : a, b, c \in F \right\} = F[\mathbf{N}],$$

of dimension 3, since $\mathbf{I}, \mathbf{N}, \mathbf{N}^2$ are exactly the three matrices of this shape with one of a, b, c equal to 1 and the others 0. Again $\deg m_{\mathbf{N}} = 3$, so this is $F[\mathbf{N}]$ by Proposition 22.1.2.

(c) *The whole algebra.* Let $\mathbf{X} \in M_3(\mathbb{Q})'$. Commuting with $\mathbf{D} = \operatorname{diag}(1, 2, 3)$ forces $\mathbf{X}$ diagonal by the first computation, say $\mathbf{X} = \operatorname{diag}(x_1, x_2, x_3)$; and then $\mathbf{XE}_{12} = x_1 \mathbf{E}_{12}$ while $\mathbf{E}_{12}\mathbf{X} = x_2 \mathbf{E}_{12}$, so $x_1 = x_2$, and similarly $x_2 = x_3$. Hence $\mathbf{X}$ is a scalar matrix. Conversely scalar matrices commute with everything. So $Z(M_3(\mathbb{Q})) = \mathbb{Q}\mathbf{I}_3$, of dimension 1. The argument used that $1, 2, 3$ are distinct scalars; over a field of characteristic 2 or 3 they are not, which is why the general statement below is proved with matrix units instead.

The last computation deserves a clean statement over every field, because later sections use it.

Proposition 22.1.5 — The Center of the Matrix Algebra Is the Scalars

Let F be **any** field and $n \geq 1$. Then $Z(M_n(F)) = F\mathbf{I}_n$. Equivalently, for a finite-

dimensional $V \neq \{\mathbf{0}\}$, the operators commuting with every operator on V are exactly the scalar multiples of id_V.

Proof. ($\supseteq$) A scalar matrix $c\mathbf{I}_n$ satisfies $(c\mathbf{I}_n)\mathbf{X} = c\mathbf{X} = \mathbf{X}(c\mathbf{I}_n)$ by Theorem 0.9.4 (4).

($\subseteq$) For $n = 1$ the claim reads $F = F\mathbf{I}_1$, which is true, so assume $n \geq 2$. Let $\mathbf{X} = (x_{pq}) \in Z(M_n(F))$. Writing $(\mathbf{E}_{ij})_{pq} = \delta_{pi}\delta_{qj}$ and expanding both products with Theorem 0.9.2 (1),

$$(\mathbf{E}_{ij}\mathbf{X})_{pq} = \delta_{pi}\, x_{jq}, \qquad (\mathbf{X}\mathbf{E}_{ij})_{pq} = x_{pi}\, \delta_{qj}.$$

Now fix j and choose any $i \neq j$, which is possible because $n \geq 2$. Reading $\mathbf{E}_{ij}\mathbf{X} = \mathbf{X}\mathbf{E}_{ij}$ at $(p, q) = (i, q)$ with $q \neq j$ gives $x_{jq} = x_{ii}\delta_{qj} = 0$, so every off-diagonal entry in row j of $\mathbf{X}$ vanishes; and reading it at $(p, q) = (i, j)$ gives $x_{jj} = x_{ii}$. Letting j run over all indices makes $\mathbf{X}$ diagonal, and applying the second conclusion to every pair $i \neq j$ makes all its diagonal entries equal. So $\mathbf{X} = x_{11}\mathbf{I}_n$.

The statement for operators follows by choosing a basis and applying the algebra isomorphism $\mathcal{L}(V) \to M_n(F)$ recorded after Definition 22.1.3, which carries id_V to $\mathbf{I}_n$, and under which an element of the center corresponds to an element of the center. This proves the proposition.

■

Quick check. In $M_2(F)$, what is $\{\mathbf{I}_2\}'$, and what is $\{\mathbf{I}_2\}''$? Does $S'' = S$ hold for $S = \{\mathbf{I}_2\}$?

Solution. Everything commutes with $\mathbf{I}_2$, so $\{\mathbf{I}_2\}' = M_2(F)$. Then $\{\mathbf{I}_2\}'' = Z(M_2(F)) = F\mathbf{I}_2$ by Proposition 22.1.5. So $S \subsetneq S''$ here: S'' is the one-dimensional space of scalar matrices, while S is a single matrix. The inclusion of Proposition 22.1.4 (c) is genuinely an inclusion, and S'' should be read as "the smallest thing S cannot be distinguished from by commutation".

Remark. Both commutants in Example (Commutants of three matrices) (a), (b) came out equal to the algebra generated by the matrix. That is not automatic. For $\mathbf{A} = \mathbf{I}_n$ with $n \geq 2$, the algebra $F[\mathbf{A}]$ is the one-dimensional space of scalar matrices, while $\{\mathbf{A}\}' = M_n(F)$ has dimension n^2. The exact condition is that the minimal and characteristic polynomials of $\mathbf{A}$ agree, which is Chapter 9 §05's condition for a cyclic vector to exist; **that equivalence is quoted here and not proved**, and nothing in this chapter depends on it.

Warning. An algebra is not a group, and the theory of this chapter never assumes an inverse. In $F[x]$ the only elements with a multiplicative inverse are the non-zero constants, since $\deg(pq) = \deg p + \deg q$; in $M_n(F)$ the invertible elements are the non-singular matrices, a proper subset; in $F[G]$ the warning above produced two non-zero elements with product 0. Every argument below that wants to divide must first produce an inverse, and most of them cannot.

22.1.7 Exercises

22.1.7.1 A. Check your understanding

Exercise A1.

(a) State the three clauses in the definition of a subalgebra, and say which one the strictly upper triangular matrices fail.

(b) Give the definition of the commutant S' of a subset S of an algebra A, and say why S itself need not be a subalgebra.

(c) True or false, with a reason: a linear bijection $\varphi\colon A \to B$ with $\varphi(xy) = \varphi(x)\varphi(y)$ for all x, y is an algebra isomorphism.

(d) What is $\dim F[G]$, and what is $\dim F[T]$ for an operator T on a finite-dimensional space?

Solution.

(a) (SA1) a subspace, (SA2) closed under products, (SA3) contains 1_A. The strictly upper triangular matrices fail (SA3), since $\mathbf{I}_n$ has non-zero diagonal.

(b) $S' = \{a \in A : as = sa \text{ for every } s \in S\}$ (Definition 22.1.6). The definition quantifies over the elements of S one at a time and asks nothing of S as a set, so S may be a single element, a finite list, or any subset at all.

(c) True — but note that $\varphi(1_A) = 1_B$ is a separate requirement in general, which here follows from bijectivity: for every $u \in B$, writing $u = \varphi(x)$, we get $\varphi(1_A)u = \varphi(1_A x) = u$ and likewise on the other side, so $\varphi(1_A)$ is an identity of B and equals 1_B by uniqueness of identities. The statement is true for bijective φ; it is false without bijectivity, as the zero map shows.

(d) $\dim F[G] = |G|$ (Definition 22.1.5) and $\dim F[T] = \deg m_T$ (Proposition 22.1.2).

22.1.7.2 B. Practice

Exercise B1: Determine which are subalgebras.

Determine which of the following are subalgebras of the stated algebra. Justify your answer, naming the exact clause that fails when one does.

(a) $\{\mathbf{A} \in M_2(F) : a_{21} = 0\}$ inside $M_2(F)$.

(b) $\{\mathbf{A} \in M_2(F) : a_{12} = a_{21}\}$ inside $M_2(F)$.

(c) $\{p \in F[x] : p(0) = p(1)\}$ inside $F[x]$.

(d) $\{c\,\mathrm{id}_V + N : c \in F,\ N^2 = 0\}$ inside $\mathcal{L}(V)$, for $\dim V = 3$.

Solution.

(a) A subalgebra: this is $\mathcal{T}_2$, handled in Example (Six subalgebras) (b).

(b) **Not** a subalgebra. The set is the symmetric matrices, a subspace containing $\mathbf{I}_2$, so (SA1) and (SA3) hold. But (SA2) fails: $\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right) = \left(\begin{smallmatrix}0&0\\1&0\end{smallmatrix}\right)$, which is not symmetric.

(c) A subalgebra. It is the kernel of the linear functional $p \mapsto p(0) - p(1)$, hence

a subspace; it contains 1; and if $p(0) = p(1)$ and $q(0) = q(1)$ then $(pq)(0) = p(0)q(0) = p(1)q(1) = (pq)(1)$ by Theorem 0.8.5.

(d) **Not** a subalgebra, because it is not even a subspace: (SA1) fails. Take $N_1 = \mathbf{E}_{12}$ and $N_2 = \mathbf{E}_{23}$, both squaring to 0. Their sum $N = \mathbf{E}_{12} + \mathbf{E}_{23}$ has $N^2 = \mathbf{E}_{13} \neq 0$ and $N^3 = 0$, so N is not of the listed form: if $N = c\,\mathrm{id}_V + M$ with $M^2 = 0$, then $M = N - c\,\mathrm{id}_V$ and $0 = M^2 = N^2 - 2cN + c^2\,\mathrm{id}_V$, whose diagonal entries in the standard basis are all c^2; so $c = 0$, and then $M = N$ with $N^2 \neq 0$.

Exercise B2: A commutant.

Let $\mathbf{D} = \mathrm{diag}(1, 1, 2) \in M_3(\mathbb{Q})$. Compute $\{\mathbf{D}\}'$ and its dimension, and compare it with $\dim \mathbb{Q}[\mathbf{D}]$. Hence show that $\{\mathbf{D}\}' \neq \mathbb{Q}[\mathbf{D}]$.

Solution. As in Example (Commutants of three matrices), $\mathbf{DX} = \mathbf{XD}$ says $(d_i - d_j)x_{ij} = 0$ with $(d_1, d_2, d_3) = (1, 1, 2)$. The coefficient vanishes exactly for $(i, j) \in \{(1,1), (1,2), (2,1), (2,2), (3,3)\}$, so

$$\{\mathbf{D}\}' = \left\{ \begin{pmatrix} p & q & 0 \\ r & s & 0 \\ 0 & 0 & t \end{pmatrix} \right\},$$

of dimension 5.

For $\mathbb{Q}[\mathbf{D}]$: the polynomial $(x-1)(x-2)$ annihilates $\mathbf{D}$, and no polynomial of degree 1 does, since $a\mathbf{I} + b\mathbf{D} = 0$ would give $a + b = 0$ and $a + 2b = 0$, hence $a = b = 0$. So $m_{\mathbf{D}} = (x-1)(x-2)$ and $\dim \mathbb{Q}[\mathbf{D}] = 2$ by Proposition 22.1.2. Since $5 \neq 2$, the two algebras differ; concretely $\mathbf{E}_{12} \in \{\mathbf{D}\}'$ is not a polynomial in $\mathbf{D}$, because every such polynomial is diagonal.

Exercise B3: Cayley for the quaternions.

Let $\mathbb{H}$ be the quaternions with ordered basis $\mathcal{B} = (1, \mathbf{i}, \mathbf{j}, \mathbf{k})$ over $\mathbb{R}$, where 1 denotes $\mathbf{I}_2$. Compute the matrices of $L_{\mathbf{i}}$ and $L_{\mathbf{j}}$ in $\mathcal{B}$, and verify that they satisfy $L_{\mathbf{i}}^2 = -\mathbf{I}_4$ and $L_{\mathbf{i}}L_{\mathbf{j}} = L_{\mathbf{k}}$.

Solution. By Definition 13.12.3, $\mathbf{i} \cdot 1 = \mathbf{i}$, $\mathbf{ii} = -1$, $\mathbf{ij} = \mathbf{k}$ and $\mathbf{ik} = -\mathbf{j}$. Writing the coordinate vectors of these four images as columns,

$$[L_{\mathbf{i}}]_{\mathcal{B}}^{\mathcal{B}} = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

Likewise $\mathbf{j} \cdot 1 = \mathbf{j}$, $\mathbf{ji} = -\mathbf{k}$, $\mathbf{jj} = -1$, $\mathbf{jk} = \mathbf{i}$, so

$$[L_{\mathbf{j}}]_{\mathcal{B}}^{\mathcal{B}} = \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}.$$

Squaring the first gives $-\mathbf{I}_4$, and multiplying the two in this order gives the matrix

with columns $(0,0,0,1),(0,0,1,0),(0,-1,0,0),(-1,0,0,0)$, which is the matrix of $L_{\mathbf{k}}$ computed the same way from $\mathbf{k}\cdot 1=\mathbf{k}$, $\mathbf{ki}=\mathbf{j}$, $\mathbf{kj}=-\mathbf{i}$, $\mathbf{kk}=-1$. Both checks also follow from Theorem 22.1.3 without computing: L is multiplicative, so $L_{\mathbf{i}}L_{\mathbf{i}}=L_{\mathbf{ii}}=L_{-1}=-\mathbf{I}_4$ and $L_{\mathbf{i}}L_{\mathbf{j}}=L_{\mathbf{ij}}=L_{\mathbf{k}}$. This exhibits $\mathbb{H}$ as a subalgebra of $M_4(\mathbb{R})$.

22.1.7.3 C. Going deeper

Exercise C1: The center of a group algebra.

Let G be a finite group and F a field. For $g\in G$, the **conjugacy class** of g is $K_g=\{hgh^{-1}:h\in G\}$, and the **class sum** is $z_g=\sum_{k\in K_g}k\in F[G]$.

(a) Prove that $x=\sum_g a_g\,g$ lies in $Z(F[G])$ if and only if $a_{hgh^{-1}}=a_g$ for all $g,h\in G$.

(b) Deduce that the distinct class sums form a basis of $Z(F[G])$, so that $\dim Z(F[G])$ is the number of conjugacy classes of G.

(c) Compute $\dim Z(F[S_3])$.

Hint for (a): by bilinearity it is enough to test commutation against the basis elements $h\in G$.

Solution.

(a) By bilinearity, x is central if and only if $xh=hx$ for every $h\in G$, equivalently $h^{-1}xh=x$ for every h (multiply by h^{-1}, which exists in G). Now

$$h^{-1}xh=\sum_g a_g\,h^{-1}gh=\sum_u a_{huh^{-1}}\,u,$$

where the second equality substitutes $u=h^{-1}gh$, that is, $g=huh^{-1}$; this is a bijection of G, so it merely relabels the sum. Comparing coefficients with $x=\sum_u a_u u$, which is legitimate because the u are a basis, gives $h^{-1}xh=x$ for all h exactly when $a_{huh^{-1}}=a_u$ for all u,h.

(b) Being conjugate is an equivalence relation on G: $g=ege^{-1}$; if $g'=hgh^{-1}$ then $g=h^{-1}g'(h^{-1})^{-1}$; and conjugating twice is conjugating by the product. So G is the disjoint union of its distinct classes $K_1,\dots,K_r$. By (a), a central element has a constant coefficient on each class, so $Z(F[G])$ is exactly the span of the class sums $z_1,\dots,z_r$; and these are independent, because they are sums over **disjoint** non-empty sets of basis vectors. Hence $\dim Z(F[G])=r$.

(c) Conjugate elements satisfy the same equations $g^k=e$: expanding and canceling the inner pairs $h^{-1}h$ gives $(hgh^{-1})^k=hg^kh^{-1}$, which equals e exactly when $g^k=e$. Now S_3 splits into three sets by this test: $\{e\}$; the three transpositions, which are the elements with $g^2=e\neq g$; and the two 3-cycles, which are the elements with $g^3=e\neq g$. No conjugacy class can meet two of these sets. Each of them is a single class: $(1\ 3)(1\ 2)(1\ 3)^{-1}=(2\ 3)$ and $(2\ 3)(1\ 2)(2\ 3)^{-1}=(1\ 3)$ make the three transpositions conjugate, and $(1\ 2)(1\ 2\ 3)(1\ 2)^{-1}=(1\ 3\ 2)$ makes the two 3-cycles conjugate. So $r=3$ and $\dim Z(F[S_3])=3$.

Exercise C2: Generated by two matrix units.

Work in $M_2(F)$.

(a) Compute $F\langle\{\mathbf{E}_{12}\}\rangle$ and its dimension.

(b) Compute $F\langle\{\mathbf{E}_{12}, \mathbf{E}_{21}\}\rangle$ and its dimension.

(c) Deduce that adding one generator can change the commutant from an algebra of dimension 2 to the scalars, and compute both commutants.

Solution.

(a) $\mathbf{E}_{12}^2 = 0$, so by Proposition 22.1.1 the generated algebra is $\operatorname{span}(\mathbf{I}_2, \mathbf{E}_{12})$, of dimension 2. It is $F[\mathbf{E}_{12}]$, which matches Proposition 22.1.2 since $m_{\mathbf{E}_{12}} = x^2$.

(b) The words include $\mathbf{E}_{12}\mathbf{E}_{21} = \mathbf{E}_{11}$ and $\mathbf{E}_{21}\mathbf{E}_{12} = \mathbf{E}_{22}$, so the generated algebra contains all four matrix units and is $M_2(F)$, of dimension 4.

(c) $\{\mathbf{E}_{12}\}'$: writing $\mathbf{X} = (x_{ij})$, $\mathbf{E}_{12}\mathbf{X}$ has first row (x_{21}, x_{22}) and second row zero, while $\mathbf{X}\mathbf{E}_{12}$ has second column (x_{11}, x_{21}) and first column zero. Equality forces $x_{21} = 0$ and $x_{22} = x_{11}$, so $\{\mathbf{E}_{12}\}' = \operatorname{span}(\mathbf{I}_2, \mathbf{E}_{12})$, of dimension 2. By Proposition 22.1.4 (b), $\{\mathbf{E}_{12}, \mathbf{E}_{21}\}' \subseteq \{\mathbf{E}_{12}\}'$, and it equals $Z(M_2(F)) = F\mathbf{I}_2$ by part (b) and Proposition 22.1.5. One extra generator cuts the commutant from dimension 2 to dimension 1.

Exercise C3: Is the group algebra ever a field?.

Let G be a finite group with $|G| \geq 2$ and let F be any field.

(a) Pick $g \neq e$ in G of order $m \geq 2$, meaning $g^m = e$ and $g^i \neq e$ for $1 \leq i < m$. (Such an m exists: the powers $g, g^2, \ldots$ cannot all be distinct in a finite group, and canceling gives $g^i = e$ for some $i \geq 1$.) Show that $x = 1 - g$ and $y = 1 + g + \cdots + g^{m-1}$ satisfy $xy = 0$ with $x \neq 0$ and $y \neq 0$.

(b) Deduce that $F[G]$ is never a field, and never isomorphic to a subalgebra of a field.

(c) Is $F[G]$ ever commutative for $|G| \geq 2$? Give an example or a proof that it is not.

Solution.

(a) The powers $1, g, \ldots, g^{m-1}$ are distinct elements of G: if $g^i = g^j$ with $0 \leq i < j \leq m - 1$ then $g^{j-i} = e$ with $1 \leq j - i < m$, contradicting minimality of m (cancellation is Theorem 0.10.1 (4)). So $x \neq 0$ and $y \neq 0$, both being non-zero combinations of distinct basis vectors. Expanding,

$$xy = \sum_{i=0}^{m-1} g^i - \sum_{i=0}^{m-1} g^{i+1} = 1 - g^m = 1 - 1 = 0.$$

(b) In a field, and more generally in any subalgebra of a field, a product of two non-zero elements is non-zero: if $xy = 0$ and $x \neq 0$ then $y = x^{-1}(xy) = 0$. Part (a) produces a violation, so $F[G]$ is not a field and embeds in none. (An algebra with such a pair x, y is said to have *zero divisors*.)

(c) Yes, whenever G is abelian: then $g_i g_j = g_j g_i$ on basis elements, and bilinearity extends the identity to all of $F[G]$. For example $F[\mathbb{Z}/2\mathbb{Z}]$ is commutative of dimension 2. Part (b) says it is still not a field, which is consistent: $\mathbb{Q}[\mathbb{Z}/2\mathbb{Z}] \cong \mathbb{Q} \times \mathbb{Q}$, a commutative algebra with zero divisors.

22.2 Ideals and Quotients

Subalgebras are the parts of an algebra one can multiply inside. Ideals are the parts one can divide by. Chapter 14 §10 introduced two-sided ideals for one purpose, to cut the Clifford algebra out of the tensor algebra; here they become the tool for taking an algebra apart. Two things are new. First, in a non-commutative algebra there are **three** kinds of ideal, and the difference decides every statement below. Second, the main theorem of the section says that the matrix algebra has no two-sided ideals at all — which is why matrix algebras are the atoms out of which the rest of the chapter builds everything.

22.2.1 Three kinds of ideal

Section 1 left a set unexplained. In $M_2(F)$ the matrices $a\mathbf{E}_{11}$ form a subspace closed under products, but not a subalgebra: the identity is missing. What kind of object is it? Look instead at the slightly bigger set

$$C_1 = \{\mathbf{X} \in M_2(F) : \text{column 2 of } \mathbf{X} \text{ is } \mathbf{0}\} = \operatorname{span}(\mathbf{E}_{11}, \mathbf{E}_{21}).$$

Multiplying on the **left** by anything keeps a matrix in C_1, because $\mathbf{AX}$ has k-th column $\mathbf{Ax}_k$ (Theorem 0.9.2), so a zero column stays zero. Multiplying on the **right** does not: $\mathbf{E}_{11}\mathbf{E}_{12} = \mathbf{E}_{12} \notin C_1$. Absorption on one side is a genuine phenomenon, and it needs its own name.

An ideal is a subspace that absorbs multiplication: a left ideal from the left, a right ideal from the right, a two-sided ideal from both.

Definition 22.2.1 — Left and Right Ideals

Let A be an algebra over F and let $I \subseteq A$ be a **subspace**. Then I is

(a) a **left ideal** of A if $ax \in I$ **for every** $a \in A$ and **every** $x \in I$;
(b) a **right ideal** of A if $xa \in I$ **for every** $a \in A$ and **every** $x \in I$.

A **two-sided ideal** is a subspace that is both, which is Definition 14.10.3. When A is commutative the three notions coincide, and we say **ideal**.

Read the quantifiers. The multiplier a runs over the **whole** algebra, not over I; being closed among one's own elements, which is clause (SA2) of a subalgebra, is a different and much weaker condition. And the definition is not symmetric: in C_1 above, "every a" works on the left and fails on the right.

Example. (Ideals in five algebras)

(a) In any algebra A: $\{0\}$ and A.
(b) In $F[x]$: the sets $\langle p \rangle$ of Definition 5.2.1.
(c) In $M_n(F)$: the column ideal C_j of matrices whose columns other than the j-th are zero.
(d) In $M_n(F)$: the set $R_U = \{\mathbf{X} : \operatorname{col}(\mathbf{X}) \subseteq U\}$ for a subspace $U \subseteq F^n$.
(e) In any algebra A: the kernel of an algebra homomorphism $\varphi\colon A \to B$.

Say in each case which of the three kinds of ideal is meant.

Solution.

(a) Two-sided, and these are the degenerate cases: $\{0\}$ absorbs everything because $a0 = 0$, and A absorbs everything because there is nowhere else to go.

(b) Two-sided, because $F[x]$ is commutative. Chapter 5's (I1)–(I3) are exactly Definition 22.2.1 read in a commutative algebra, with (I1) and (I2) replaced by the stronger requirement that I be a subspace — which is no change, since $cf = (c1)f \in I$ for a scalar c by (I3).

(c) A **left** ideal, by the computation above, of dimension n. Not a right ideal for $n \geq 2$: $\mathbf{E}_{jj}\mathbf{E}_{jk} = \mathbf{E}_{jk} \notin C_j$ for $k \neq j$.

(d) A **right** ideal: $\mathrm{col}(\mathbf{XA}) \subseteq \mathrm{col}(\mathbf{X}) \subseteq U$, because each column of $\mathbf{XA}$ is a combination of the columns of $\mathbf{X}$ (Theorem 0.9.2). Not a left ideal in general: for $U = \mathrm{span}(\mathbf{e}_1) \subseteq F^2$, $\mathbf{E}_{11} \in R_U$ but $\mathbf{E}_{21}\mathbf{E}_{11} = \mathbf{E}_{21}$ has column space $\mathrm{span}(\mathbf{e}_2) \not\subseteq U$.

(e) Two-sided: this is Lemma 14.10.5 (c).

The non-example is the one Chapter 14 already gave, and it is worth repeating because it is the mistake to avoid. The diagonal matrices in $M_2(F)$ form a subspace closed under products — a subalgebra, in fact — and are **not** an ideal of any kind: $\mathbf{E}_{11}$ is diagonal, while $\mathbf{E}_{21}\mathbf{E}_{11} = \mathbf{E}_{21}$ and $\mathbf{E}_{11}\mathbf{E}_{12} = \mathbf{E}_{12}$ are not. Closure under one's own products is not absorption.

Why insist on absorbing products with the whole algebra? Because that is exactly the condition under which the quotient vector space A/I inherits a multiplication, as Lemma 14.10.5 (a) shows: the computation $x'y' = xy + uy + xw + uw$ needs uy and xw to lie in I when u, w do, with x, y arbitrary. The condition is necessary as well: taking $u = 0$ leaves xw, which must lie in I for every $x \in A$ and $w \in I$, and taking $w = 0$ leaves uy, which must lie in I for every $u \in I$ and $y \in A$. A one-sided ideal gives only half of that, and half is not enough.

Warning. A two-sided ideal is almost never a subalgebra, and a subalgebra is almost never an ideal. If a left ideal I contains an invertible element u, then for every $a \in A$ we have $a = (au^{-1})u \in I$, so $I = A$. In particular a **proper** ideal of any kind contains no invertible element, hence does not contain 1_A, hence fails (SA3). The only ideal that is a subalgebra is A itself.

Quick check. In $M_2(F)$, is $\mathrm{span}(\mathbf{E}_{11})$ a left ideal? A right ideal?

Solution. Neither. It is a subspace, but $\mathbf{E}_{21}\mathbf{E}_{11} = \mathbf{E}_{21} \notin \mathrm{span}(\mathbf{E}_{11})$, so it is not a left ideal, and $\mathbf{E}_{11}\mathbf{E}_{12} = \mathbf{E}_{12} \notin \mathrm{span}(\mathbf{E}_{11})$, so it is not a right ideal. It is closed under its own products, which is why it looked like something in the warning of Section 1; it is neither a subalgebra nor an ideal. The smallest left ideal containing it is C_1, and the smallest two-sided ideal containing it is all of $M_2(F)$, by the theorem below.

22.2.2 Matrix units multiply in one line

Everything about ideals of $M_n(F)$ follows from a single product rule. Recall that the **matrix unit** $\mathbf{E}_{ij}$ has a 1 in position (i, j) and zeros elsewhere, and that the n^2 matrix units are a basis of $M_n(F)$ (Example (Standard Bases)).

Lemma 22.2.1 — The Matrix Unit Product Rule

Let F be a field, $n \geq 1$, and $1 \leq i, j, k, l \leq n$. Then, in $M_n(F)$,

$$\mathbf{E}_{ij}\mathbf{E}_{kl} = \delta_{jk}\,\mathbf{E}_{il}, \qquad \text{and} \qquad \mathbf{E}_{ij}\,\mathbf{X}\,\mathbf{E}_{kl} = x_{jk}\,\mathbf{E}_{il} \quad \text{for every } \mathbf{X} = (x_{pq}).$$

Moreover $\mathbf{E}_{11} + \mathbf{E}_{22} + \cdots + \mathbf{E}_{nn} = \mathbf{I}_n$.

Proof. Write $(\mathbf{E}_{ij})_{pq} = \delta_{pi}\delta_{qj}$, which is the definition of the matrix unit. By Theorem 0.9.2 (1),

$$(\mathbf{E}_{ij}\mathbf{E}_{kl})_{pq} = \sum_{r} \delta_{pi}\delta_{rj}\,\delta_{rk}\delta_{ql} = \delta_{pi}\delta_{ql}\sum_{r}\delta_{rj}\delta_{rk} = \delta_{jk}\,\delta_{pi}\delta_{ql},$$

since the only surviving term of the last sum is $r = j$, which contributes 1 when $k = j$ and 0 otherwise. The right-hand side is the (p, q) entry of $\delta_{jk}\mathbf{E}_{il}$.

For the second identity, expand $\mathbf{X} = \sum_{r,s} x_{rs}\mathbf{E}_{rs}$ in the basis of matrix units and use bilinearity together with the first identity twice:

$$\mathbf{E}_{ij}\mathbf{X}\mathbf{E}_{kl} = \sum_{r,s} x_{rs}\,\mathbf{E}_{ij}\mathbf{E}_{rs}\mathbf{E}_{kl} = \sum_{r,s} x_{rs}\,\delta_{jr}\delta_{sk}\,\mathbf{E}_{il} = x_{jk}\,\mathbf{E}_{il}.$$

The last statement is the observation that $\sum_i \mathbf{E}_{ii}$ has (p, q) entry $\sum_i \delta_{pi}\delta_{qi} = \delta_{pq}$. This proves the lemma. ∎

The second identity is the one to remember: *sandwiching a matrix between two matrix units extracts one entry and moves it to a chosen place.* Choosing i and l freely, a single non-zero entry of $\mathbf{X}$ can be moved anywhere.

22.2.3 The matrix algebra is simple

An algebra whose only two-sided ideals are $\{0\}$ and itself is called **simple**; Section 3 makes this a definition, adding the clause that the algebra be non-zero. The theorem says that matrix algebras are simple over every field.

Theorem 22.2.2 — The Matrix Algebra Has No Proper Two-Sided Ideals

Let F be **any** field and $n \geq 1$. The only two-sided ideals of $M_n(F)$ are $\{0\}$ and $M_n(F)$. Consequently, for a finite-dimensional vector space $V \neq \{\mathbf{0}\}$ over F, the only two-sided ideals of $\mathcal{L}(V)$ are $\{0\}$ and $\mathcal{L}(V)$.

Idea. An ideal that contains anything non-zero contains a matrix with some entry $x_{jk} \neq 0$. Sandwich it: Lemma 22.2.1 turns that one entry into an arbitrary matrix unit, up to the non-zero scalar x_{jk}, which we may divide out. Once the ideal has all n^2 matrix units, it has their span, and it also has their sum, which is $\mathbf{I}_n$.

Proof. Both $\{0\}$ and $M_n(F)$ are two-sided ideals. Let $\mathcal{I}$ be a two-sided ideal with $\mathcal{I} \neq \{0\}$, and choose $\mathbf{X} \in \mathcal{I}$ with $\mathbf{X} \neq 0$. Then some entry x_{jk} is non-zero; fix such a pair (j, k).

Let i and l be arbitrary. Since $\mathcal{I}$ absorbs multiplication on both sides, $\mathbf{E}_{ij}\mathbf{X}\mathbf{E}_{kl} \in \mathcal{I}$, and by Lemma 22.2.1 this element is $x_{jk}\mathbf{E}_{il}$. As $x_{jk} \neq 0$ it is invertible in F, and $\mathcal{I}$ is a subspace, so

$$\mathbf{E}_{il} = x_{jk}^{-1}\left(x_{jk}\mathbf{E}_{il}\right) \in \mathcal{I}.$$

Hence $\mathcal{I}$ contains every matrix unit. The matrix units span $M_n(F)$ (Example (Standard Bases)) and $\mathcal{I}$ is a subspace, so $\mathcal{I} = M_n(F)$.

For $\mathcal{L}(V)$, fix an ordered basis of V and use the algebra isomorphism $\mathcal{L}(V) \to M_n(F)$ recorded after Definition 22.1.3. An algebra isomorphism carries two-sided ideals to two-sided ideals, since it is a linear bijection and $\varphi(ax) = \varphi(a)\varphi(x)$ in both directions. This proves the theorem.

■

Nothing in the proof used anything about F beyond the existence of x_{jk}^{-1}, which is the field axiom. The theorem holds over $\mathbb{Q}$, over $\mathbb{C}$, and over $\mathbb{F}_2$ alike, and it is the reason matrix algebras will turn out to be the building blocks in this chapter's structure theorem: they cannot be broken.

One consequence is worth recording; §03 proves it again for every simple algebra.

Corollary 22.2.3 — Homomorphisms out of a Matrix Algebra Are Injective

Let F be a field, $n \geq 1$, and let $\varphi\colon M_n(F) \to B$ be an algebra homomorphism into any F-algebra $B \neq \{0\}$. Then φ is injective.

Proof. By Lemma 14.10.5 (c), $\ker\varphi$ is a two-sided ideal of $M_n(F)$, so by Theorem 22.2.2 it is $\{0\}$ or $M_n(F)$. If $\ker\varphi = M_n(F)$, then $1_B = \varphi(\mathbf{I}_n) = 0$, and then $b = 1_B b = 0$ for every $b \in B$, contradicting $B \neq \{0\}$. So $\ker\varphi = \{0\}$ and φ is injective (Theorem 3.2.3).

■

Warning. "Simple" says nothing about one-sided ideals. $M_n(F)$ has no two-sided ideals other than the two obvious ones, and for $n \geq 2$ it has a whole lattice of left ideals, as the next result shows. Whenever a statement in this chapter says "ideal", check which kind is meant before using it.

22.2.4 The left ideals of the matrix algebra

The left ideals are not trivial, and they are worth knowing exactly: they are indexed by subspaces of row vectors, and the smallest of them are the column ideals.

Proposition 22.2.4 — The Left Ideals of $M_n(F)$

Let F be a field and $n \geq 1$. For a subspace $W \subseteq M_{1\times n}(F)$ of row vectors, put

$$L_W \coloneqq \{\mathbf{X} \in M_n(F) : \operatorname{row}(\mathbf{X}) \subseteq W\}.$$

(a) L_W is a left ideal of $M_n(F)$, and $\dim L_W = n \dim W$.

(b) Every left ideal L of $M_n(F)$ equals L_W for exactly one W, namely the span of the union of the row spaces of the elements of L:

$$W = \operatorname{span}\Big(\bigcup_{\mathbf{X}\in L} \operatorname{row}(\mathbf{X})\Big).$$

(c) $W \mapsto L_W$ is an inclusion-preserving bijection from subspaces of $M_{1\times n}(F)$ onto left ideals of $M_n(F)$. The minimal non-zero left ideals are the L_W with $\dim W = 1$.

(d) Taking $W = \operatorname{span}(\mathbf{e}_j^\top)$ gives the column ideal C_j of Example (Ideals in five algebras) (c), of dimension n, and $M_n(F) = C_1 \oplus \cdots \oplus C_n$ as a direct sum of left ideals.

Idea. Two facts drive everything. First, left multiplication can only shrink the row space: row i of $\mathbf{AX}$ is a combination of the rows of $\mathbf{X}$. Second, left multiplication can produce **every** matrix whose rows lie in the row space of $\mathbf{X}$, because the rows of $\mathbf{AX}$ are arbitrary combinations of the rows of $\mathbf{X}$, one combination per row and chosen independently. So a left ideal is determined by the row vectors it can reach, and it contains every matrix built from them.

Proof. Throughout we use two consequences of Theorem 0.9.2 (3): row i of $\mathbf{AX}$ is (row i of $\mathbf{A}$) $\mathbf{X}$; and for a row vector $\mathbf{a}^\top \in M_{1\times n}(F)$, the product $\mathbf{a}^\top\mathbf{X}$ is the combination of the rows of $\mathbf{X}$ with weights $a_1, \ldots, a_n$, so that

$$\operatorname{row}(\mathbf{X}) = \{\, \mathbf{a}^\top\mathbf{X} \;:\; \mathbf{a}^\top \in M_{1\times n}(F) \,\}. \tag{$*$}$$

(a) L_W is a subspace: every row of $\mathbf{X} + c\mathbf{Y}$ is the corresponding row of $\mathbf{X}$ plus c times that of $\mathbf{Y}$, hence lies in W when both do. It is a left ideal: each row of $\mathbf{AX}$ lies in $\operatorname{row}(\mathbf{X}) \subseteq W$ by the first consequence. For the dimension, the map $M_n(F) \to \big(M_{1\times n}(F)\big)^n$ sending $\mathbf{X}$ to its list of rows is a linear bijection, and it carries L_W onto $W \times \cdots \times W$ — the rows may be chosen from W independently of one another. So $\dim L_W = n \dim W$ by Theorem 3.9.1.

(b) Let L be a left ideal and put $W \coloneqq \operatorname{span}\big(\bigcup_{\mathbf{X}\in L} \operatorname{row}(\mathbf{X})\big)$, a subspace of $M_{1\times n}(F)$ by Theorem 1.3.1; then $L \subseteq L_W$ by construction.
For the reverse inclusion, choose $\mathbf{X}_1, \ldots, \mathbf{X}_m \in L$ with $W = \operatorname{row}(\mathbf{X}_1) + \cdots + \operatorname{row}(\mathbf{X}_m)$. Such a choice exists: W is a subspace of the n-dimensional space $M_{1\times n}(F)$, so it has a finite basis; each basis vector is by Definition 1.3.2 a finite combination of row vectors drawn from the spaces $\operatorname{row}(\mathbf{X})$ with $\mathbf{X} \in L$, and each such space is a subspace, so that basis vector lies in the sum of the finitely many $\operatorname{row}(\mathbf{X})$ involved. Collecting the $\mathbf{X}$ used across the whole basis gives $\mathbf{X}_1, \ldots, \mathbf{X}_m \in L$ with $W \subseteq \operatorname{row}(\mathbf{X}_1) + \cdots + \operatorname{row}(\mathbf{X}_m)$, and the reverse containment holds because each $\operatorname{row}(\mathbf{X}_t) \subseteq W$. Let $\mathbf{Y} \in L_W$ and let $\mathbf{y}_1^\top, \ldots, \mathbf{y}_n^\top$ be its rows, all in W. Each $\mathbf{y}_p^\top$ lies in $W = \operatorname{row}(\mathbf{X}_1) + \cdots + \operatorname{row}(\mathbf{X}_m)$, hence is a sum of elements

of the row$(\mathbf{X}_t)$, so by $(*)$ there are row vectors $\mathbf{a}_{pt}^{\top}$ with

$$\mathbf{y}_p^{\top} = \sum_{t=1}^{m} \mathbf{a}_{pt}^{\top}\,\mathbf{X}_t \qquad (1 \le p \le n).$$

Let $\mathbf{A}_t \in M_n(F)$ be the matrix whose p-th row is $\mathbf{a}_{pt}^{\top}$. Then row p of $\sum_t \mathbf{A}_t\mathbf{X}_t$ is $\sum_t \mathbf{a}_{pt}^{\top}\mathbf{X}_t = \mathbf{y}_p^{\top}$, so $\mathbf{Y} = \sum_t \mathbf{A}_t\mathbf{X}_t$. Each $\mathbf{A}_t\mathbf{X}_t$ lies in L because L is a left ideal, and L is a subspace, so $\mathbf{Y} \in L$. Hence $L = L_W$.
Uniqueness: L_W determines W, because $W = \operatorname{span}\big(\bigcup_{\mathbf{X}\in L_W} \operatorname{row}(\mathbf{X})\big)$. Indeed that span is contained in W by definition, and it contains every $\mathbf{a}^{\top} \in W$, since the matrix $\mathbf{e}_1\mathbf{a}^{\top}$, whose first row is $\mathbf{a}^{\top}$ and whose other rows are zero, lies in L_W.

(c) If $W \subseteq W'$ then $L_W \subseteq L_{W'}$; conversely $L_W \subseteq L_{W'}$ forces $W \subseteq W'$, by the description of W just given. With (b), the map is a bijection, and it preserves and reflects inclusion, so it matches minimal non-zero left ideals with minimal non-zero subspaces, which are the lines.

(d) A matrix has all its rows in $\operatorname{span}(\mathbf{e}_j^{\top})$ exactly when every entry outside column j is zero, which is the description of C_j; its dimension is $n \cdot 1 = n$ by (a). Every $\mathbf{X}$ is the sum of its columns placed in the corresponding C_j, and a matrix lying in C_j and in the sum of the others is zero, so the sum is direct. This proves the proposition.

■

Remark. Everything transposes. Since $(\mathbf{XA})^{\top} = \mathbf{A}^{\top}\mathbf{X}^{\top}$, the linear bijection $\mathbf{X} \mapsto \mathbf{X}^{\top}$ carries left ideals onto right ideals and back. Applying it to the proposition, and writing $U = \{\mathbf{a} \in F^n : \mathbf{a}^{\top} \in W\}$, the right ideals of $M_n(F)$ are exactly the sets $R_U = \{\mathbf{X} : \operatorname{col}(\mathbf{X}) \subseteq U\}$ of Example (Ideals in five algebras) (d), for subspaces $U \subseteq F^n$, with $\dim R_U = n \dim U$. It is worth keeping the two statements apart: column spaces classify **right** ideals, row spaces classify **left** ideals.

22.2.5 Quotients, and the first isomorphism theorem

Chapter 14 §10 did the work. Lemma 14.10.5 says that the quotient **space** $A/\mathcal{I}$ of Chapter 3 (Definition 3.9.3) carries exactly one multiplication making $\pi\colon A \to A/\mathcal{I}$ multiplicative, namely $(x+\mathcal{I})(y+\mathcal{I}) = xy+\mathcal{I}$, and that with it $A/\mathcal{I}$ is an algebra with identity $1_A+\mathcal{I}$. We give the object its name.

Definition 22.2.2 — Quotient Algebra

Let A be an algebra over F and $\mathcal{I}$ a **two-sided** ideal of A. The **quotient algebra** $A/\mathcal{I}$ is the quotient vector space $A/\mathcal{I}$ with the multiplication $(x+\mathcal{I})(y+\mathcal{I}) = xy+\mathcal{I}$ of Lemma 14.10.5, and $\pi\colon A \to A/\mathcal{I}$, $\pi(x) = x+\mathcal{I}$, is the **quotient homomorphism**.

Two facts come for free. The ideal must be two-sided: a *merely* one-sided ideal gives a quotient vector space, but the product of cosets is not well defined on it. And when A is finite-dimensional,

$\dim(A/\mathcal{I}) = \dim A - \dim \mathcal{I}$ by Theorem 3.9.5.

Theorem 22.2.5 — First Isomorphism Theorem for Algebras

Let $\varphi\colon A \to B$ be a homomorphism of F-algebras. Then $\ker\varphi$ is a two-sided ideal of A, $\operatorname{im}\varphi$ is a subalgebra of B, and the rule

$$\bar{\varphi}\colon A/\ker\varphi \to B, \qquad \bar{\varphi}(x + \ker\varphi) = \varphi(x),$$

defines an injective algebra homomorphism with image $\operatorname{im}\varphi$. Hence

$$A/\ker\varphi \cong \operatorname{im}\varphi$$

as F-algebras.

Idea. Chapter 3 already produced the linear isomorphism; all that is left is to see that it respects products, and that is one line, because the product on the quotient was **defined** so that π is multiplicative.

Proof. $\ker\varphi$ is a two-sided ideal by Lemma 14.10.5 (c). $\operatorname{im}\varphi$ is a subalgebra of B: it is a subspace (Theorem 3.2.2), it is closed under products since $\varphi(x)\varphi(y) = \varphi(xy)$, and it contains $1_B = \varphi(1_A)$.

Write $K = \ker\varphi$. By Theorem 3.9.7, $\bar{\varphi}$ is a well-defined **linear** map, it is injective, its image is $\operatorname{im}\varphi$, and $\bar{\varphi}\circ\pi = \varphi$.

It is multiplicative. Every element of A/K is $\pi(x)$ for some $x \in A$, and by Definition 22.2.2 and the multiplicativity of φ,

$$\bar{\varphi}\big(\pi(x)\pi(y)\big) = \bar{\varphi}\big(\pi(xy)\big) = \varphi(xy) = \varphi(x)\varphi(y) = \bar{\varphi}(\pi(x))\,\bar{\varphi}(\pi(y)).$$

It is unital: $\bar{\varphi}(1_{A/K}) = \bar{\varphi}(\pi(1_A)) = \varphi(1_A) = 1_B$. So $\bar{\varphi}$ is an injective algebra homomorphism onto $\operatorname{im}\varphi$, hence an algebra isomorphism $A/K \to \operatorname{im}\varphi$. This proves the theorem.

■

The theorem turns every surjective homomorphism into a quotient, and that is how quotient algebras are recognized in practice: build a homomorphism, compute its kernel, and read off the answer. Here are two instances.

Example. (The group algebra of a cyclic group)

Let F be a field, $n \geq 1$, and $G = \mathbb{Z}/n\mathbb{Z}$ written multiplicatively as $\{1, g, \dots, g^{n-1}\}$ with $g^n = 1$. Show that

$$F[G] \cong F[x]/\langle x^n - 1\rangle.$$

Solution. Example (Three group algebras) (b) produced an algebra homomorphism $\varepsilon\colon F[x] \to F[G]$ with $\varepsilon(p) = \sum_i c_i g^i$ for $p = \sum_i c_i x^i$, showed that it is surjective, and identified $\ker\varepsilon = \langle x^n - 1\rangle$. Note that $\langle x^n - 1\rangle$ is a two-sided ideal of $F[x]$, since $F[x]$ is

commutative. By Theorem 22.2.5,

$$F[x]/\langle x^n - 1\rangle \cong \operatorname{im}\varepsilon = F[G].$$

Both sides have dimension n: the left by Theorem 5.6.5, the right by Definition 22.1.5. This pays off the promise made in Section 1, and it says something the group alone does not: the group algebra of a cyclic group is a ring of polynomials with one relation.

The second instance needs a two-element algebra built from F. For F-algebras A and B, the **product algebra** $A \times B$ is the product vector space (Definition 3.9.1) with componentwise multiplication $(a,b)(a',b') = (aa', bb')$. Bilinearity, associativity and the identity $(1_A, 1_B)$ are inherited componentwise, so $A \times B$ is an algebra, of dimension $\dim A + \dim B$ (Theorem 3.9.1). We need only $F \times F$, of dimension 2.

Example. (Upper triangular matrices modulo their strictly upper part)

Let $\mathcal{T}_2$ be the upper triangular matrices in $M_2(F)$ and let $\mathcal{N} = \operatorname{span}(\mathbf{E}_{12})$ be the strictly upper triangular ones.

(a) Show that $\mathcal{N}$ is a two-sided ideal of $\mathcal{T}_2$.
(b) Identify $\mathcal{T}_2/\mathcal{N}$.

Solution. Write a general element of $\mathcal{T}_2$ as $\mathbf{U} = \left(\begin{smallmatrix} a & b \\ 0 & c \end{smallmatrix}\right)$ and note

$$\begin{pmatrix} a & b \\ 0 & c \end{pmatrix}\begin{pmatrix} p & q \\ 0 & r \end{pmatrix} = \begin{pmatrix} ap & aq + br \\ 0 & cr \end{pmatrix}. \tag{$\dagger$}$$

(a) $\mathcal{N}$ is the set of elements of $\mathcal{T}_2$ with $a = c = 0$, a subspace. Putting $a = c = 0$ in ($\dagger$) gives a product with both diagonal entries 0, and putting $p = r = 0$ does the same; so $\mathcal{N}$ absorbs multiplication on both sides.

(b) Define $\varphi\colon \mathcal{T}_2 \to F \times F$ by $\varphi(\mathbf{U}) = (a, c)$. It is linear, it sends $\mathbf{I}_2$ to $(1,1)$, and by ($\dagger$) it is multiplicative, since the diagonal of a product of upper triangular matrices is the product of the diagonals. It is surjective, since $\varphi(\operatorname{diag}(a,c)) = (a,c)$, and its kernel is exactly $\mathcal{N}$. By Theorem 22.2.5,

$$\mathcal{T}_2/\mathcal{N} \cong F \times F.$$

A dimension check: $\dim \mathcal{T}_2 = 3$, $\dim \mathcal{N} = 1$, $\dim(F \times F) = 2 = 3 - 1$, as Theorem 3.9.5 requires.

So $\mathcal{T}_2$ is **not** simple: it has a proper non-zero two-sided ideal, and dividing by it leaves the most transparent algebra there is, a product of copies of F. Theorem 22.2.2 says $M_2(F)$ admits no such surgery. That contrast — an algebra with an ideal to divide out, against one with none — is the division the rest of the chapter runs on.

22.2.6 Exercises

22.2.6.1 A. Check your understanding

Exercise A1.

(a) Define left ideal, right ideal and two-sided ideal, and say which of the three is needed to form a quotient algebra.

(b) State the product rule for matrix units, and say which step of the proof of Theorem 22.2.2 uses that F is a field.

(c) True or false, with a reason: a two-sided ideal of an algebra A is a subalgebra of A.

(d) Give a left ideal of $M_3(F)$ of dimension 6, and say which subspace of row vectors it corresponds to.

Solution.

(a) See Definition 22.2.1: a subspace absorbing multiplication from the left, from the right, or from both. Forming a quotient algebra needs a **two-sided** ideal, because the product of cosets is otherwise not well defined (Lemma 14.10.5 (a)).

(b) $\mathbf{E}_{ij}\mathbf{E}_{kl} = \delta_{jk}\mathbf{E}_{il}$, and $\mathbf{E}_{ij}\mathbf{X}\mathbf{E}_{kl} = x_{jk}\mathbf{E}_{il}$ (Lemma 22.2.1). The field is used when dividing by the non-zero scalar x_{jk} to extract $\mathbf{E}_{il}$ from $x_{jk}\mathbf{E}_{il}$.

(c) False, unless $\mathcal{I} = A$. A proper ideal contains no invertible element, in particular not 1_A, so (SA3) fails; see the warning after Example (Ideals in five algebras).

(d) L_W with $W = \operatorname{span}(\mathbf{e}_1^\top, \mathbf{e}_2^\top)$, the matrices whose third column is zero; $\dim L_W = 3 \cdot 2 = 6$ by Proposition 22.2.4 (a).

22.2.6.2 B. Practice

Exercise B1: Determine which are ideals.

Determine, for each of the following subspaces, whether it is a left ideal, a right ideal, a two-sided ideal, or none. Justify your answer.

(a) $\{\mathbf{X} \in M_2(F) : x_{11} + x_{22} = 0\}$.

(b) $\{\mathbf{X} \in M_2(F) : \text{row 2 of } \mathbf{X} \text{ is } \mathbf{0}\}$.

(c) $\{\mathbf{X} \in M_3(F) : \mathbf{X}\mathbf{e}_1 = \mathbf{0}\}$.

(d) $\{p \in F[x] : p(0) = 0\}$ inside $F[x]$.

Solution.

(a) None. It is a subspace, but $\mathbf{E}_{12}$ lies in it while $\mathbf{E}_{21}\mathbf{E}_{12} = \mathbf{E}_{22}$ does not, so it is not a left ideal; and $\mathbf{E}_{12}\mathbf{E}_{21} = \mathbf{E}_{11}$ is not in it, so it is not a right ideal. (One may also argue from Theorem 22.2.2: a two-sided ideal of dimension 3 is impossible.)

(b) A **right** ideal, not a left ideal. The set is a subspace, and right multiplication keeps the condition: by Theorem 0.9.2 (3), row 2 of $\mathbf{X}\mathbf{A}$ is (row 2 of $\mathbf{X}$) $\mathbf{A} = \mathbf{0}$. Left multiplication does not: $\mathbf{E}_{11}$ has second row $\mathbf{0}$, while $\mathbf{E}_{21}\mathbf{E}_{11} = \mathbf{E}_{21}$ does not.

(c) A **left** ideal, not a right ideal. It is L_W for $W = \operatorname{span}(\mathbf{e}_2^\top, \mathbf{e}_3^\top)$: a matrix kills $\mathbf{e}_1$ exactly when its first column is zero, that is, when every row lies in W. Left multiplication keeps the condition since $(\mathbf{A}\mathbf{X})\mathbf{e}_1 = \mathbf{A}(\mathbf{X}\mathbf{e}_1) = \mathbf{0}$. Right multiplication does not: $\mathbf{E}_{12}\mathbf{e}_1 = \mathbf{0}$, while $(\mathbf{E}_{12}\mathbf{E}_{21})\mathbf{e}_1 = \mathbf{E}_{11}\mathbf{e}_1 = \mathbf{e}_1 \neq \mathbf{0}$.

(d) A two-sided ideal, since $F[x]$ is commutative: it is $\langle x \rangle$ by Theorem 5.1.3, and $(hp)(0) = h(0)p(0) = 0$.

Exercise B2: A quotient computed.

Let $A = F[x]/\langle x^2 \rangle$.

(a) Write down a basis of A and its multiplication table.
(b) Show that $\mathcal{I} = \operatorname{span}(x + \langle x^2 \rangle)$ is a two-sided ideal of A and identify $A/\mathcal{I}$.
(c) Show that A is not isomorphic to $F \times F$.

Solution.

(a) By Theorem 5.6.5, $\dim A = 2$, with basis $(1 + \langle x^2 \rangle,\ x + \langle x^2 \rangle)$. Write 1 and t for these. The table is $1 \cdot 1 = 1$, $1 \cdot t = t \cdot 1 = t$, and $t^2 = x^2 + \langle x^2 \rangle = 0$.
(b) $\mathcal{I} = \operatorname{span}(t)$ is a subspace, and $(a + bt)t = at \in \mathcal{I}$, $t(a + bt) = at \in \mathcal{I}$, so it absorbs on both sides. The map $\varphi\colon A \to F$, $a + bt \mapsto a$, is linear, sends 1 to 1, and is multiplicative because $(a + bt)(a' + b't) = aa' + (ab' + a'b)t$. Its kernel is $\mathcal{I}$, so $A/\mathcal{I} \cong F$ by Theorem 22.2.5.
(c) In $F \times F$ the equation $y^2 = 0$ forces $y = 0$, since a product of scalars vanishes only when a factor does. In A the non-zero element t satisfies $t^2 = 0$. An algebra isomorphism preserves squares and sends 0 to 0, so no isomorphism exists.

Exercise B3: An ideal generated.

Inside $M_3(F)$, let $\mathcal{I} = \langle \mathbf{E}_{23} \rangle$ be the two-sided ideal generated by $\mathbf{E}_{23}$ in the sense of Definition 14.10.3. Compute $\mathcal{I}$, and do the same for the **left** ideal generated by $\mathbf{E}_{23}$, that is, $\operatorname{span}\{\mathbf{A}\mathbf{E}_{23} : \mathbf{A} \in M_3(F)\}$.

Solution. By Definition 14.10.3, $\mathcal{I}$ is spanned by the elements $\mathbf{A}\mathbf{E}_{23}\mathbf{B}$. Taking $\mathbf{A} = \mathbf{E}_{i2}$ and $\mathbf{B} = \mathbf{E}_{3l}$ gives $\mathbf{E}_{i2}\mathbf{E}_{23}\mathbf{E}_{3l} = \mathbf{E}_{il}$ by Lemma 22.2.1, for all i and l. So $\mathcal{I}$ contains every matrix unit and $\mathcal{I} = M_3(F)$, of dimension 9. This is Theorem 22.2.2 in a single instance.

The left ideal is different. By $(*)$ in the proof of Proposition 22.2.4, $\operatorname{row}(\mathbf{E}_{23}) = \operatorname{span}(\mathbf{e}_3^\top)$, so $\{\mathbf{A}\mathbf{E}_{23}\}$ is exactly the set of matrices all of whose rows are multiples of $\mathbf{e}_3^\top$, that is, the column ideal C_3, of dimension 3. Generating on one side and on two sides give a three-dimensional and a nine-dimensional answer.

22.2.6.3 C. Going deeper

Exercise C1: All the ideals of the upper triangular algebra.

Let $\mathcal{T}_2$ be the upper triangular matrices in $M_2(F)$, with basis $(\mathbf{E}_{11}, \mathbf{E}_{12}, \mathbf{E}_{22})$.

(a) Prove that $\mathcal{J}_1 = \operatorname{span}(\mathbf{E}_{11}, \mathbf{E}_{12})$ and $\mathcal{J}_2 = \operatorname{span}(\mathbf{E}_{12}, \mathbf{E}_{22})$ are two-sided ideals.
(b) Prove that $\{0\}$, $\operatorname{span}(\mathbf{E}_{12})$, $\mathcal{J}_1$, $\mathcal{J}_2$ and $\mathcal{T}_2$ are the **only** two-sided ideals of $\mathcal{T}_2$.
(c) Identify $\mathcal{T}_2/\mathcal{J}_1$ and $\mathcal{T}_2/\mathcal{J}_2$.

Hint for (b): if an ideal contains an element with $a \neq 0$, multiply it by $\mathbf{E}_{11}$ on both sides.

Solution. Throughout write $\mathbf{U} = \left(\begin{smallmatrix} a & b \\ 0 & c \end{smallmatrix}\right)$ and use (†) of Example (Upper triangular matrices modulo their strictly upper part).

(a) $\mathcal{J}_1$ is the set of $\mathbf{U}$ with $c = 0$. Putting $c = 0$ in (†) gives a product with lower right entry $cr = 0$; putting $r = 0$ does the same. So $\mathcal{J}_1$ absorbs on both sides. Symmetrically, $\mathcal{J}_2$ is the set with $a = 0$, and (†) gives upper left entry ap, which vanishes if $a = 0$ or $p = 0$.

(b) Let $\mathcal{I}$ be a two-sided ideal and take $\mathbf{U} \in \mathcal{I}$. By (†), $\mathbf{E}_{11}\mathbf{U}\mathbf{E}_{11} = a\mathbf{E}_{11}$ and $\mathbf{E}_{22}\mathbf{U}\mathbf{E}_{22} = c\mathbf{E}_{22}$, both in $\mathcal{I}$. Also $\mathbf{E}_{11}\mathbf{U}\mathbf{E}_{22} = b\mathbf{E}_{12} \in \mathcal{I}$.
Case 1: some element of $\mathcal{I}$ has $a \neq 0$. Then $\mathbf{E}_{11} \in \mathcal{I}$, hence $\mathbf{E}_{12} = \mathbf{E}_{11}\mathbf{E}_{12} \in \mathcal{I}$, so $\mathcal{J}_1 \subseteq \mathcal{I}$. If in addition some element has $c \neq 0$, then $\mathbf{E}_{22} \in \mathcal{I}$ and $\mathcal{I} = \mathcal{T}_2$; otherwise every element has $c = 0$ and $\mathcal{I} = \mathcal{J}_1$.
Case 2: every element of $\mathcal{I}$ has $a = 0$. If some element has $c \neq 0$, then $\mathbf{E}_{22} \in \mathcal{I}$, hence $\mathbf{E}_{12} = \mathbf{E}_{12}\mathbf{E}_{22} \in \mathcal{I}$, so $\mathcal{J}_2 \subseteq \mathcal{I} \subseteq \mathcal{J}_2$ and $\mathcal{I} = \mathcal{J}_2$. Otherwise every element has $a = c = 0$, so $\mathcal{I} \subseteq \operatorname{span}(\mathbf{E}_{12})$, and $\mathcal{I}$ is $\{0\}$ or $\operatorname{span}(\mathbf{E}_{12})$.
These five exhaust the possibilities.

(c) $\mathbf{U} \mapsto c$ is a surjective algebra homomorphism $\mathcal{T}_2 \to F$ by (†), with kernel $\mathcal{J}_1$; so $\mathcal{T}_2/\mathcal{J}_1 \cong F$ by Theorem 22.2.5. Symmetrically $\mathbf{U} \mapsto a$ gives $\mathcal{T}_2/\mathcal{J}_2 \cong F$.

Exercise C2: Simplicity over a small field, and a failure.

(a) Verify Theorem 22.2.2 by hand for $M_2(\mathbb{F}_2)$, starting from the ideal generated by $\mathbf{E}_{12} + \mathbf{E}_{21}$.

(b) Let $A = F \times F$. Show that A has exactly four two-sided ideals, and conclude that a commutative algebra of dimension 2 can fail to be simple.

(c) Deduce that $M_2(F)$ and $F^4 = F \times F \times F \times F$ are not isomorphic as F-algebras, although they have the same dimension.

Solution.

(a) Let $\mathbf{X} = \mathbf{E}_{12} + \mathbf{E}_{21}$ and let $\mathcal{I}$ be the two-sided ideal it generates. Its $(1,2)$ entry is $1 \neq 0$, so by Lemma 22.2.1, $\mathbf{E}_{i1}\mathbf{X}\mathbf{E}_{2l} = x_{12}\mathbf{E}_{il} = \mathbf{E}_{il}$ for all $i, l \in \{1,2\}$. Hence $\mathcal{I}$ contains $\mathbf{E}_{11}, \mathbf{E}_{12}, \mathbf{E}_{21}, \mathbf{E}_{22}$ and so all of $M_2(\mathbb{F}_2)$. Over $\mathbb{F}_2$ no division was needed, because the non-zero entry was already 1.

(b) Let $\mathcal{I} \subseteq F \times F$ be an ideal and put $e_1 = (1,0)$, $e_2 = (0,1)$. For $(u,v) \in \mathcal{I}$ we get $(u,0) = e_1(u,v) \in \mathcal{I}$ and $(0,v) \in \mathcal{I}$. So $\mathcal{I}$ is determined by whether it contains a pair with $u \neq 0$ and whether it contains a pair with $v \neq 0$, giving $\{0\}$, $F \times \{0\}$, $\{0\} \times F$ and $F \times F$. Each of these four is indeed an ideal, by componentwise multiplication. The two middle ones are proper and non-zero, so $F \times F$ is not simple.

(c) $M_2(F)$ has exactly two two-sided ideals (Theorem 22.2.2), while F^4 has more: the same argument as in (b) shows that $F \times \{0\} \times \{0\} \times \{0\}$ is a proper non-zero ideal. An algebra isomorphism carries two-sided ideals bijectively to two-sided ideals, so no isomorphism can exist. Both algebras have dimension 4, so dimension alone classifies nothing.

Exercise C3: Left ideals and null spaces.

Let F be a field and $n \geq 1$.

(a) For a subspace $U \subseteq F^n$, prove that $N_U = \{\mathbf{X} \in M_n(F) : \mathbf{X}\mathbf{u} = \mathbf{0} \text{ for every } \mathbf{u} \in U\}$ is a left ideal of $M_n(F)$.

(b) Prove that $\dim N_U = n(n - \dim U)$.

(c) Prove that $U \mapsto N_U$ is an **inclusion-reversing** bijection from subspaces of F^n onto left ideals of $M_n(F)$, and describe N_U in the language of Proposition 22.2.4.

Hint for (b): a matrix kills every vector of U exactly when each of its rows annihilates U.

Solution.

(a) N_U is the intersection over $\mathbf{u} \in U$ of the null spaces of the linear maps $\mathbf{X} \mapsto \mathbf{X}\mathbf{u}$, hence a subspace. If $\mathbf{X} \in N_U$ and $\mathbf{A} \in M_n(F)$, then $(\mathbf{A}\mathbf{X})\mathbf{u} = \mathbf{A}(\mathbf{X}\mathbf{u}) = \mathbf{0}$, so $\mathbf{A}\mathbf{X} \in N_U$.

(b) Let $\mathbf{a}^\top$ be a row of $\mathbf{X}$. The entries of $\mathbf{X}\mathbf{u}$ are the numbers $\mathbf{a}^\top\mathbf{u}$ as $\mathbf{a}^\top$ runs over the rows, so $\mathbf{X}\mathbf{u} = \mathbf{0}$ for every $\mathbf{u} \in U$ exactly when every row of $\mathbf{X}$ annihilates U, that is, when $\operatorname{row}(\mathbf{X}) \subseteq W_U$, where W_U is the space of row vectors annihilating U. Identifying a row vector $\mathbf{a}^\top$ with the functional $\mathbf{u} \mapsto \mathbf{a}^\top\mathbf{u}$, which is a linear bijection $M_{1\times n}(F) \to (F^n)^*$ by Theorem 4.1.1, the space W_U corresponds to U^0, so $\dim W_U = n - \dim U$ by Theorem 4.2.2. Hence $N_U = L_{W_U}$, and Proposition 22.2.4 (a) gives $\dim N_U = n(n - \dim U)$.

(c) It is enough to show that $U \mapsto W_U$, which under the identification of (b) is $U \mapsto U^0$, is an inclusion-reversing bijection from subspaces of F^n onto subspaces of $M_{1\times n}(F)$; composing with the inclusion-preserving bijection $W \mapsto L_W$ of Proposition 22.2.4 (c) then gives the claim, since $N_U = L_{W_U}$ by (b).

It reverses inclusions by Theorem 4.2.3 (a), and it is injective by Corollary 4.3.5. For surjectivity, let W be a subspace of $(F^n)^*$ of dimension k, with basis $\varphi_1, \dots, \varphi_k$, and put $U = \ker\varphi_1 \cap \cdots \cap \ker\varphi_k$. By Theorem 4.6.7, U has codimension k, so $\dim U = n - k$ and $\dim U^0 = k$ by Theorem 4.2.2. Every φ_i vanishes on U, so $W \subseteq U^0$; equal dimensions give $W = U^0$.

22.3 Simple and Semisimple Algebras

Section 2 found that $M_n(F)$ has no two-sided ideals except the two unavoidable ones: as an algebra it cannot be collapsed. This section is about a second kind of object that is indecomposable — not the algebra, but a space the algebra acts on — and about what happens when a space does break apart. The main theorem says that "every invariant subspace can be split off" and "the space is a sum of unbreakable pieces" are one condition wearing two faces, and that condition is what the rest of the chapter runs on. At the end we check the new vocabulary against the old: an operator is semisimple in Chapter 9's sense exactly when the algebra it generates acts semisimply.

Throughout, F is **any** field. Nothing in this section asks it to be algebraically closed or to

have a particular characteristic; the hypotheses start biting in the next section. Algebras are associative, unital and finite-dimensional over F, as agreed in Section 1.

22.3.1 Two meanings of the word simple

Section 2 proved that $M_n(F)$ has exactly two two-sided ideals (Theorem 22.2.2), while $F[x]$ — the infinite-dimensional standing exception of Section 1 — has infinitely many. That difference deserves a name.

A simple algebra is one that cannot be collapsed: forming the quotient by an ideal either changes nothing or destroys everything.

Definition 22.3.1 — Simple Algebra

An F-algebra A is **simple** if $A \neq \{0\}$ and the only two-sided ideals (Definition 14.10.3) of A are $\{0\}$ and A itself.

In words: two conditions, and the first is not decoration. The zero algebra has only one ideal, so without the clause $A \neq \{0\}$ it would count as simple and every theorem below would need an exception for it.

Examples.

- **The field itself.** $A = F$ is simple: a non-zero ideal contains some $c \neq 0$, hence contains $c^{-1}c = 1$, hence everything.
- **Matrix algebras.** $M_n(F)$ is simple for every $n \geq 1$ (Theorem 22.2.2). This is the example the whole chapter is aimed at.
- **A degenerate case.** $n = 1$ recovers $M_1(F) = F$, so the two examples above are one.

Non-example by minimal change. Replace $M_n(F)$ by the algebra A of **upper triangular** 2×2 matrices over F. It is a subalgebra of $M_2(F)$ of dimension 3, with basis $\mathbf{E}_{11}, \mathbf{E}_{12}, \mathbf{E}_{22}$, and the set

$$\mathcal{N} = \left\{ \begin{pmatrix} 0 & b \\ 0 & 0 \end{pmatrix} : b \in F \right\}$$

is a two-sided ideal of A: it is a subspace, and

$$\begin{pmatrix} a & c \\ 0 & d \end{pmatrix} \begin{pmatrix} 0 & b \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & ab \\ 0 & 0 \end{pmatrix},$$
$$\begin{pmatrix} 0 & b \\ 0 & 0 \end{pmatrix} \begin{pmatrix} a & c \\ 0 & d \end{pmatrix} = \begin{pmatrix} 0 & bd \\ 0 & 0 \end{pmatrix}.$$

Since $\{0\} \neq \mathcal{N} \neq A$, the algebra A is not simple. The clause that fails is the second one; $A \neq \{0\}$ is fine.

- **Another non-example, the infinite-dimensional one.** $F[x]$ has the ideal $\langle x \rangle$ (Proposition 5.2.1), the polynomials with zero constant term (Example (First Ideals) (b)), which is neither $\{0\}$ nor $F[x]$.

Why this definition. Section 2 identified ideals with kernels: the kernel of an algebra homomorphism out of A is a two-sided ideal, and conversely every two-sided ideal is the kernel of the map onto the quotient algebra (Definition 22.2.2, Theorem 22.2.5). Simplicity therefore

says that A admits no interesting image under a homomorphism, which is the following one-line consequence.

Proposition 22.3.1 — Maps Out of a Simple Algebra

Let A be a simple F-algebra, let $B \neq \{0\}$ be an F-algebra, and let $\varphi\colon A \to B$ be an algebra homomorphism (Definition 22.1.2). Then φ is injective.

Proof. Since $B \neq \{0\}$ we have $1_B \neq 0$: otherwise $y = 1_B y = 0$ for every $y \in B$. The kernel of φ is a two-sided ideal of A, and it does not contain 1_A, because $\varphi(1_A) = 1_B \neq 0$. So $\ker\varphi \neq A$, and simplicity forces $\ker\varphi = \{0\}$. A linear map with zero kernel is injective (Theorem 3.2.3).

■

Section 2 had already seen the case $A = M_n(F)$, which is simple by Theorem 22.2.2: that is Corollary 22.2.3. So a simple algebra has only one image under a homomorphism worth the name: itself. Section 6 will turn this around and recognize the **semisimple** algebras, over an algebraically closed field, as products of matrix algebras; its Exercise C1 picks out the simple ones among them as the single matrix algebras.

22.3.2 Algebras acting on spaces

An algebra is already a set of operators, by Section 1's embedding theorem (Theorem 22.1.3). But the same abstract algebra acts on many different spaces — $M_n(F)$ acts on F^n, on itself, on $M_n(F)$ by conjugation — and the differences between those actions are the subject. We need a word for one of them.

Definition 22.3.2 — Representation of an Algebra, and Invariant Subspaces

Let A be an F-algebra. A **representation** of A on a finite-dimensional vector space V over F is an algebra homomorphism

$$\rho\colon A \to \mathcal{L}(V),$$

so that ρ is linear, $\rho(ab) = \rho(a)\rho(b)$, and $\rho(1_A) = \mathrm{id}_V$. We then call V an **A-space** and abbreviate $\rho(a)(\mathbf{v})$ to $a\mathbf{v}$. A subspace $U \subseteq V$ is **A-invariant** if $a\mathbf{u} \in U$ for every $a \in A$ and every $\mathbf{u} \in U$.

In words: the multiplication of A is carried to composition of operators, and — the clause that is easy to overlook — **the identity of A must act as the identity of V**. Two standing examples:

- **The tautological representation.** If $A \subseteq \mathcal{L}(V)$ is a subalgebra containing id_V (Definition 22.1.1), the inclusion is a representation. This is the case we usually mean when we say "an algebra of operators on V".
- **The regular representation.** A acts on itself by left multiplication: $\rho(a)(b) = ab$. Associativity gives $\rho(ab) = \rho(a)\rho(b)$, bilinearity gives linearity, and $\rho(1_A) = \mathrm{id}_A$. Here the

A-invariant subspaces are precisely the **left ideals** of Section 2.

Non-example by minimal change. Take $A = F$, $V = F^2$, and $\rho(c) = \mathbf{0}$ for every c. This is linear and multiplicative, but $\rho(1) = \mathbf{0} \neq \mathrm{id}_V$, so it is not a representation. The clause that fails is unitality, and it is not a technicality: it is what makes $\mathbf{v} = 1\mathbf{v}$ lie in $A\mathbf{v}$, a step used twice below.

Now the indecomposable actions.

An irreducible A-space is one with nothing inside it for A to see.

Definition 22.3.3 — Irreducible, or Simple, A-space

An A-space V is **irreducible** — equivalently, **simple** — if $V \neq \{\mathbf{0}\}$ and the only A-invariant subspaces of V are $\{\mathbf{0}\}$ and V.

Both words are standard and we use them interchangeably. Again two clauses, and again the first is needed: $\{\mathbf{0}\}$ has only one subspace and must be excluded by hand, exactly as the zero algebra was.

Examples.

- **Lines.** Any A-space of dimension 1 is irreducible, whatever A is, since its only subspaces are $\{\mathbf{0}\}$ and itself. These are the smallest possible pieces, and Section 4 will show that over an algebraically closed field a commutative algebra has no others.
- **The column space of a matrix algebra.** F^n is an irreducible $M_n(F)$-space. Indeed, let $U \neq \{\mathbf{0}\}$ be invariant and pick $\mathbf{u} \in U$ with $\mathbf{u} \neq \mathbf{0}$. Given any $\mathbf{w} \in F^n$, extend $\mathbf{u}$ to a basis of F^n (Theorem 1.6.5) and let $\mathbf{X}$ be the matrix of the linear map sending $\mathbf{u}$ to $\mathbf{w}$ and the other basis vectors to $\mathbf{0}$ (Theorem 3.1.6). Then $\mathbf{w} = \mathbf{X}\mathbf{u} \in U$. So $U = F^n$.

Non-example by minimal change. Shrink $M_2(F)$ to the upper triangular algebra A above, still acting on F^2. The line $F\mathbf{e}_1$ is A-invariant, because an upper triangular $\mathbf{X}$ has $\mathbf{X}\mathbf{e}_1 = x_{11}\mathbf{e}_1$. So F^2 is not an irreducible A-space; the clause that fails is the second.

Warning. **Two different words are both spelled "simple".** An algebra is simple when it has no proper non-zero **two-sided ideal**; an A-space is simple when it has no proper non-zero **invariant subspace**. The first does not imply the second. For $n \geq 2$ the algebra $M_n(F)$ is simple, yet $M_n(F)$ as a space over itself is **not**: the matrices whose columns other than the first are zero form a left ideal that is neither $\{0\}$ nor all of $M_n(F)$, that is, a proper non-zero invariant subspace of the regular representation.

Quick check. Let $A \subseteq M_2(F)$ be the algebra of **diagonal** matrices and let $V = F^2$. Which subspaces of V are A-invariant? Is V irreducible?

Solution. The invariant subspaces are $\{\mathbf{0}\}$, $F\mathbf{e}_1$, $F\mathbf{e}_2$ and F^2. Each of these four is invariant because $\mathrm{diag}(d_1, d_2)$ fixes each coordinate line. No other line $F\mathbf{v}$ with $\mathbf{v} = (x, y)$ is: $\mathbf{E}_{11}\mathbf{v} = (x, 0)$ must be a multiple $c(x, y)$ of $\mathbf{v}$, and if both $x \neq 0$ and $y \neq 0$ then $cy = 0$ forces $c = 0$ and hence $x = 0$, a contradiction. So V is not irreducible: $F\mathbf{e}_1$ is a proper non-zero invariant subspace.

22.3.3 Splitting a space into pieces

Here is the phenomenon the section is built on. Take $V = F^2$ and the single operator $\mathbf{N} = \mathbf{J}_2(0)$, that is, $\mathbf{N}\mathbf{e}_1 = \mathbf{0}$ and $\mathbf{N}\mathbf{e}_2 = \mathbf{e}_1$. The line $F\mathbf{e}_1$ is invariant. Is there an invariant complement? A complement of a line in F^2 is a line $F\mathbf{v}$ with $\mathbf{v} = (x, y)$ and $y \neq 0$, and $\mathbf{N}\mathbf{v} = (y, 0)$ is a non-zero element of $F\mathbf{e}_1$, which meets $F\mathbf{v}$ only in $\mathbf{0}$. So $\mathbf{N}\mathbf{v} \notin F\mathbf{v}$: there is **no** invariant complement, and F^2 does not break into invariant lines.

Compare $\mathbf{D} = \operatorname{diag}(1, 2)$, where $F^2 = F\mathbf{e}_1 \oplus F\mathbf{e}_2$ splits perfectly. The difference between these two pictures is the definition we want.

An algebra acts semisimply when every invariant subspace can be split off.

Definition 22.3.4 — Semisimple Action, Semisimple Algebra

Let A be an F-algebra and V an A-space. We say A **acts semisimply on** V if **every** A-invariant subspace $U \subseteq V$ has an A-invariant complement: a subspace $W \subseteq V$ with

$$V = U \oplus W \qquad \text{and} \qquad W \text{ is } A\text{-invariant.}$$

The algebra A is **semisimple** if it acts semisimply on **itself** in the regular representation — that is, if every left ideal of A has a complementary left ideal.

In words: the first notion is a property of an action, the second a property of the algebra alone, obtained by feeding the algebra its own most faithful space. The examples come after the theorem that makes the definition usable.

Warning. **Acting semisimply depends on the space, not only on the algebra.** The upper triangular algebra A does not act semisimply on F^2, as we check below. Yet it does act semisimply on the one-dimensional space F through $\mathbf{X} \mapsto x_{11}$, for the silly reason that a one-dimensional space has no invariant subspace to split off. Always say **which space**. The unqualified phrase "A is semisimple" is reserved for the regular representation, and a proposition below shows that this is the right choice: a semisimple algebra acts semisimply on every space.

The first thing to know is that the property passes to invariant subspaces. Without this, no induction on dimension gets started.

Lemma 22.3.2 — Splitting Is Inherited by Invariant Subspaces

Let A act semisimply on a finite-dimensional A-space V, and let $W \subseteq V$ be A-invariant. Then W, with the action $a \mapsto \rho(a)|_W$, is an A-space, and A acts semisimply on W.

Idea. An invariant subspace U of W is also one of V, so it has an invariant complement U' in V. That complement is too big; cut it down to $U' \cap W$ and check that nothing was lost.

Proof. Since W is A-invariant, $\rho(a)|_W \in \mathcal{L}(W)$ for every $a \in A$, and $a \mapsto \rho(a)|_W$ is linear, multiplicative and sends 1_A to id_W; so it is a representation.

Let $U \subseteq W$ be A-invariant. Then U is an A-invariant subspace of V, so there is an

A-invariant U' with $V = U \oplus U'$. Put $W' = U' \cap W$, which is A-invariant because U' and W are.

$U + W' = W$: the inclusion $\subseteq$ holds since $U \subseteq W$ and $W' \subseteq W$. Conversely, let $\mathbf{w} \in W$ and write $\mathbf{w} = \mathbf{u} + \mathbf{u}'$ with $\mathbf{u} \in U$, $\mathbf{u}' \in U'$. Then $\mathbf{u}' = \mathbf{w} - \mathbf{u} \in W$, because both $\mathbf{w}$ and $\mathbf{u}$ lie in W; hence $\mathbf{u}' \in U' \cap W = W'$ and $\mathbf{w} \in U + W'$.

The sum is direct: $U \cap W' \subseteq U \cap U' = \{\mathbf{0}\}$.

Therefore $W = U \oplus W'$ with W' an A-invariant complement, which is what semisimplicity of the action on W asks for.

■

Now the theorem. It is the section's real content, and every later section uses it.

Theorem 22.3.3 — Complete Reducibility

Let A be an F-algebra and let V be a finite-dimensional A-space. The following are equivalent:

(a) A acts semisimply on V;
(b) V is a sum of irreducible A-invariant subspaces;
(c) V is a direct sum of finitely many irreducible A-invariant subspaces.

Here a sum over the empty family is $\{\mathbf{0}\}$, so all three hold when $V = \{\mathbf{0}\}$. No hypothesis is placed on F.

Idea. For (a) $\Rightarrow$ (c), induct on $\dim V$. The smallest non-zero invariant subspace is automatically irreducible: it has no room for a proper one. Split it off using (a), and apply the inductive hypothesis to the complement — which is legitimate precisely because of Lemma 22.3.2. For (b) $\Rightarrow$ (a), given an invariant U, build a complement greedily out of the given irreducible pieces: add pieces to U as long as the sum stays direct, and then show that a piece left outside would have to meet the sum in $\{\mathbf{0}\}$, so it could have been added too.

Proof.

(a) $\Rightarrow$ (c). Induction on $\dim V$. If $\dim V = 0$ then V is the empty direct sum and there is nothing to prove. Let $\dim V \geq 1$ and suppose the implication holds for every A-space of smaller dimension.

Among the non-zero A-invariant subspaces of V — there is at least one, namely V — choose W of smallest dimension. Then W is irreducible: it is non-zero, and if $U \subseteq W$ is A-invariant with $U \neq \{\mathbf{0}\}$, then U is a non-zero A-invariant subspace of V, so $\dim U \geq \dim W$ by the choice of W, and $U = W$ by Theorem 1.6.8.

By (a) there is an A-invariant W' with $V = W \oplus W'$. By Lemma 22.3.2, W' is an A-space on which A acts semisimply, and $\dim W' = \dim V - \dim W < \dim V$ because $\dim W \geq 1$. The inductive hypothesis writes $W' = W_1 \oplus \cdots \oplus W_r$ with each W_i an irreducible A-invariant subspace of W'. Invariance and irreducibility refer only to the action of A, not to the ambient space, so each W_i is an irreducible A-invariant subspace

of V as well. Hence

$$V = W \oplus W_1 \oplus \cdots \oplus W_r,$$

a direct sum of finitely many irreducibles.

(c) $\Rightarrow$ (b). A direct sum is in particular a sum.

(d) $\Rightarrow$ (a). Write $V = \sum_{i \in I} W_i$ with each W_i an irreducible A-invariant subspace, and let $U \subseteq V$ be A-invariant. Call a finite subset $J \subseteq I$ **good** if the sum $U + \sum_{j \in J} W_j$ is direct. The empty set is good. Every good J satisfies

$$|J| \le \dim U + \sum_{j \in J} \dim W_j = \dim\Big(U \oplus \bigoplus_{j \in J} W_j\Big) \le \dim V,$$

where the first inequality uses $\dim W_j \ge 1$ and the middle equality is Theorem 1.7.5. So the sizes of good sets are bounded, and we may choose a good J with $|J|$ as large as possible. Put

$$W = \sum_{j \in J} W_j,$$

an A-invariant subspace, since a sum of A-invariant subspaces is A-invariant. Write $S = U \oplus W$.

Claim: $W_i \subseteq S$ for every $i \in I$. Fix i. The subspace $W_i \cap S$ is A-invariant and contained in the irreducible W_i, so it is $\{\mathbf{0}\}$ or W_i. Suppose it were $\{\mathbf{0}\}$. Then $i \notin J$, since $j \in J$ gives $W_j \subseteq S$ and $W_j \neq \{\mathbf{0}\}$. We show $J \cup \{i\}$ is good, contradicting maximality. Let

$$\mathbf{u} + \sum_{j \in J} \mathbf{w}_j + \mathbf{w}_i = \mathbf{0}, \qquad \mathbf{u} \in U,\ \mathbf{w}_j \in W_j,\ \mathbf{w}_i \in W_i.$$

Then $\mathbf{w}_i = -\big(\mathbf{u} + \sum_j \mathbf{w}_j\big) \in W_i \cap S = \{\mathbf{0}\}$, so $\mathbf{w}_i = \mathbf{0}$; and then $\mathbf{u} + \sum_j \mathbf{w}_j = \mathbf{0}$ forces $\mathbf{u} = \mathbf{0}$ and every $\mathbf{w}_j = \mathbf{0}$, because J is good (Theorem 1.7.5 (b)). So the sum over $J \cup \{i\}$ is direct, which is the contradiction. Hence $W_i \cap S = W_i$, that is, $W_i \subseteq S$.

The claim gives $V = \sum_i W_i \subseteq S$, so $V = S = U \oplus W$ with W invariant. This proves (a).

■

Two features of the proof are worth keeping. The complement produced in (b) $\Rightarrow$ (a) is a sum of some of the given pieces, so nothing new has to be constructed. And the pieces in (c) are far from unique: F^2 under the scalar matrices is a direct sum of **any** two distinct lines.

Example. (Upper Triangular Matrices Are Not Semisimple)

Let $A \subseteq M_2(F)$ be the algebra of upper triangular matrices, of dimension 3. Show that A does not act semisimply on F^2, and list the irreducible A-subspaces of F^2.

Solution. The A-invariant subspaces of F^2 are $\{\mathbf{0}\}$, $F\mathbf{e}_1$ and F^2, and no others. Certainly all three are invariant, the middle one because $\mathbf{X}\mathbf{e}_1 = x_{11}\mathbf{e}_1$ for upper triangular $\mathbf{X}$. Conversely, let $F\mathbf{v}$ be an invariant line with $\mathbf{v} = (x, y)$. Since $\mathbf{E}_{12} \in A$ and $\mathbf{E}_{12}\mathbf{v} = (y, 0)$, invariance gives $(y, 0) = c(x, y)$ for some $c \in F$. If $y \neq 0$ then $cy = 0$ gives $c = 0$, hence $y = 0$ after all; so $y = 0$ and $F\mathbf{v} = F\mathbf{e}_1$.

Now $F\mathbf{e}_1$ is an invariant subspace with no invariant complement, since a complement of a line in F^2 is a line, and $F\mathbf{e}_1$ is the only invariant one. So A does not act semisimply on F^2. The only irreducible A-subspace is $F\mathbf{e}_1$; in particular F^2 is not a sum of irreducibles, in agreement with Theorem 22.3.3.

For contrast, here is an action that does split, and it is the one Section 6 will build on.

Example. (Matrix Algebras Are Semisimple)

Show that $A = M_n(F)$ is a semisimple algebra for every $n \geq 1$.

Solution. Section 2 did the work. For $j = 1, \dots, n$ let $C_j \subseteq A$ be the column ideal: the matrices all of whose columns except the j-th are zero. By Proposition 22.2.4 (d), each C_j is a left ideal and $A = C_1 \oplus \cdots \oplus C_n$. Moreover $C_j = L_W$ for the one-dimensional space of row vectors $W = \operatorname{span}(\mathbf{e}_j^{\top})$, so C_j is a **minimal** non-zero left ideal by part (c) of the same proposition.

The A-invariant subspaces of the regular representation are the left ideals of A, so "minimal non-zero left ideal" says exactly "irreducible A-subspace". Hence the regular representation of A is a direct sum of irreducibles, and Theorem 22.3.3 makes A semisimple.

The definition of a semisimple **algebra** only looked at one space. It controls all of them.

Proposition 22.3.4 — A Semisimple Algebra Has No Other Kind of Representation

Let A be a semisimple F-algebra and let V be any finite-dimensional A-space. Then A acts semisimply on V.

Idea. Every vector $\mathbf{v}$ lies in $A\mathbf{v}$, because 1_A acts as the identity; so V is the sum of the subspaces $A\mathbf{v}$. Chop A itself into irreducible left ideals L and show each $L\mathbf{v}$ is either zero or irreducible. Then V is a sum of irreducibles and Theorem 22.3.3 finishes.

Proof. If $V = \{\mathbf{0}\}$ there is nothing to prove, so let $\dim V \geq 1$. Since A is semisimple, Theorem 22.3.3 applied to the regular representation gives $A = L_1 \oplus \cdots \oplus L_k$ with each L_m an irreducible left ideal.

Claim: for a left ideal L that is irreducible and a vector $\mathbf{v} \in V$, the subspace $L\mathbf{v} = \{a\mathbf{v} : a \in L\}$ is either $\{\mathbf{0}\}$ or an irreducible A-invariant subspace of V. It is a subspace, being the image of the linear map $a \mapsto a\mathbf{v}$ restricted to L, and it is A-invariant because $b(a\mathbf{v}) = (ba)\mathbf{v}$ with $ba \in L$. Suppose $L\mathbf{v} \neq \{\mathbf{0}\}$ and let $U \subseteq L\mathbf{v}$ be A-invariant with $U \neq \{\mathbf{0}\}$. Put

$$L_0 = \{a \in L : a\mathbf{v} \in U\}.$$

This is a subspace of L, and it is a left ideal: for $b \in A$ and $a \in L_0$ we have $ba \in L$ and $(ba)\mathbf{v} = b(a\mathbf{v}) \in U$ since U is invariant. As L is irreducible, $L_0 = \{0\}$ or $L_0 = L$. If $L_0 = \{0\}$, then every $\mathbf{u} \in U$ has the form $\mathbf{u} = a\mathbf{v}$ with $a \in L$, whence $a \in L_0 = \{0\}$ and $\mathbf{u} = \mathbf{0}$, contradicting $U \neq \{\mathbf{0}\}$. So $L_0 = L$, which says $L\mathbf{v} \subseteq U$ and therefore $U = L\mathbf{v}$. This proves the claim.

Now let $\mathbf{v} \in V$. Since $1_A\mathbf{v} = \mathbf{v}$, we have $\mathbf{v} \in A\mathbf{v} = L_1\mathbf{v} + \cdots + L_k\mathbf{v}$. Hence

$$V = \sum_{\mathbf{v}\in V} A\mathbf{v} = \sum_{\mathbf{v}\in V} \sum_{m=1}^{k} L_m\mathbf{v},$$

and discarding the summands that are $\{\mathbf{0}\}$ exhibits V as a sum of irreducible A-invariant subspaces. By Theorem 22.3.3, A acts semisimply on V.

■

22.3.4 How far from semisimple: the radical

The upper triangular algebra failed to act semisimply on F^2, and the ideal $\mathcal{N}$ was visibly to blame: it is non-zero, yet it squares to zero, so no irreducible space can feel it. That suggests measuring the failure by collecting everything invisible.

We write $\operatorname{rad} A$ for what follows. Chapter 13 §01 writes $\operatorname{rad}(\beta)$ for the radical of a bilinear form; here the argument is an algebra and the two never meet.

Definition 22.3.5 — Radical of an Algebra

Let A be an F-algebra. Its **radical** is

$$\operatorname{rad} A := \bigcap_{V} \{\, a \in A : aV = \{\mathbf{0}\} \,\},$$

where V runs over all irreducible A-spaces and $aV = \{a\mathbf{v} : \mathbf{v} \in V\}$.

In words: the elements that every irreducible representation sends to 0. The quantifier ranges over a manageable supply: if V is irreducible and $\mathbf{v} \in V$ is non-zero, then $A\mathbf{v}$ is a non-zero invariant subspace, so $V = A\mathbf{v}$ is the image of the linear map $a \mapsto a\mathbf{v}$, and $\dim V \le \dim A$.

The radical is a two-sided ideal. It is a subspace, being an intersection of kernels of linear maps; and if $a \in \operatorname{rad} A$, $x, y \in A$ and V is irreducible, then $(xay)\mathbf{v} = x\big(a(y\mathbf{v})\big) = x\mathbf{0} = \mathbf{0}$ for every $\mathbf{v} \in V$. Taking $y = 1_A$ and $x = 1_A$ in turn shows xa and ay lie in $\operatorname{rad} A$.

The first fact we want is the one the triangular example suggested.

Lemma 22.3.5 — A Nilpotent Ideal Is Invisible

Let A be an F-algebra and let $\mathcal{I} \subseteq A$ be a two-sided ideal which is **nilpotent**: for some $m \ge 1$, every product $a_1a_2\cdots a_m$ of m elements of $\mathcal{I}$ is 0. Then $\mathcal{I} \subseteq \operatorname{rad} A$.

Proof. Let V be an irreducible A-space and write $\mathcal{I}V = \operatorname{span}\{a\mathbf{v} : a \in \mathcal{I},\ \mathbf{v} \in V\}$, and more generally $\mathcal{I}^kV = \operatorname{span}\{a_1\cdots a_k\mathbf{v} : a_i \in \mathcal{I},\ \mathbf{v} \in V\}$.

The subspace $\mathcal{I}V$ is A-invariant, since $b(a\mathbf{v}) = (ba)\mathbf{v}$ with $ba \in \mathcal{I}$. By irreducibility, $\mathcal{I}V = \{\mathbf{0}\}$ or $\mathcal{I}V = V$.

Suppose $\mathcal{I}V = V$. Applying $\mathcal{I}$ to both sides, $\mathcal{I}^2V = \mathcal{I}(\mathcal{I}V) = \mathcal{I}V = V$, and repeating

gives $\mathcal{I}^k V = V$ for every $k \geq 1$. But $\mathcal{I}^m V = \{\mathbf{0}\}$ by nilpotency, so $V = \{\mathbf{0}\}$, contradicting irreducibility.

Hence $\mathcal{I}V = \{\mathbf{0}\}$, that is, every $a \in \mathcal{I}$ acts as 0 on V. Since V was an arbitrary irreducible A-space, $\mathcal{I} \subseteq \operatorname{rad} A$.

■

And the radical really does obstruct semisimplicity.

Proposition 22.3.6 — A Semisimple Algebra Has Zero Radical

Let A be a semisimple F-algebra. Then $\operatorname{rad} A = \{0\}$.

Proof. By Theorem 22.3.3 applied to the regular representation, $A = L_1 \oplus \cdots \oplus L_k$ with each L_m an irreducible A-space. Let $a \in \operatorname{rad} A$. Then a acts as 0 on each L_m, so $aL_m = \{0\}$ for every m, and therefore $aA = \{0\}$. In particular $a = a1_A = 0$.

■

Remark. The converse is also true for finite-dimensional algebras: $\operatorname{rad} A = \{0\}$ forces A to be semisimple. We do not prove it, and nothing in this book uses it; whenever semisimplicity is needed later it is established directly, by Maschke's theorem in Section 7 or by exhibiting a decomposition.

We can now finish the running example.

Quick check. Let A be the algebra of upper triangular 2×2 matrices and $\mathcal{N}$ its ideal of strictly upper triangular matrices. Using the two results above, identify $\operatorname{rad} A$ and decide whether A is a semisimple algebra. *Hint: the maps* $\mathbf{X} \mapsto x_{11}$ *and* $\mathbf{X} \mapsto x_{22}$ *go from* A *to* F.

Solution. $\operatorname{rad} A = \mathcal{N}$, and A is not semisimple.

($\supseteq$) We saw that $\mathcal{N}$ is a two-sided ideal, and $\mathcal{N}^2 = \{0\}$ because $\mathbf{E}_{12}\mathbf{E}_{12} = \mathbf{0}$. By Lemma 22.3.5, $\mathcal{N} \subseteq \operatorname{rad} A$.

($\subseteq$) For upper triangular $\mathbf{X}, \mathbf{Y}$ the product has $(\mathbf{XY})_{11} = x_{11}y_{11}$ and $(\mathbf{XY})_{22} = x_{22}y_{22}$. So $\rho_1(\mathbf{X}) = x_{11}$ and $\rho_2(\mathbf{X}) = x_{22}$ are algebra homomorphisms $A \to F$, each sending $\mathbf{I}_2$ to 1; they make F an A-space in two ways, irreducible because $\dim F = 1$. An element of $\operatorname{rad} A$ must be killed by both, so it has $x_{11} = x_{22} = 0$ and lies in $\mathcal{N}$.

Since $\operatorname{rad} A = \mathcal{N} \neq \{0\}$, Proposition 22.3.6 shows A is not a semisimple algebra.

22.3.5 Back to a single operator

Chapter 9 §08 already used the word semisimple, for an operator: T is semisimple when m_T is a product of **distinct** monic irreducible polynomials (Definition 9.8.1). That definition was about a polynomial. This section's is about invariant subspaces. They agree, and proving so is the best check that the new definition is the right one.

Fix a finite-dimensional $V \neq \{\mathbf{0}\}$ over F and $T \in \mathcal{L}(V)$, and let

$$F[T] \coloneqq \{\, p(T) : p \in F[x] \,\} \subseteq \mathcal{L}(V),$$

which is a commutative subalgebra of $\mathcal{L}(V)$ containing id_V (Proposition 22.1.2). A subspace U is $F[T]$-invariant if and only if it is T-invariant: one direction is the case $p = x$, and the other holds because $TU \subseteq U$ gives $T^k U \subseteq U$ for every k, hence $p(T)U \subseteq U$ for every p.

Theorem 22.3.7 — The Two Meanings of Semisimple Agree

Let $V \neq \{\mathbf{0}\}$ be a finite-dimensional vector space over F and let $T \in \mathcal{L}(V)$. The following are equivalent:

(a) T is semisimple in the sense of Definition 9.8.1, that is, m_T is a product of distinct monic irreducible polynomials;

(b) $F[T]$ acts semisimply on V: every T-invariant subspace has a T-invariant complement;

(c) V is a sum of irreducible $F[T]$-invariant subspaces.

No hypothesis is placed on F.

Idea.

(b) and (c) are Theorem 22.3.3 for the algebra $F[T]$, so the work is the polynomial statement (a). Forwards: the primary decomposition splits V into pieces on which the minimal polynomial is a single irreducible p, and inside such a piece **every** non-zero vector generates a cyclic subspace of dimension $\deg p$ — which leaves no room for a proper invariant subspace. Backwards: an irreducible piece is cyclic, and a factorization of its minimal polynomial would manufacture a smaller invariant subspace inside it; so each piece contributes one irreducible polynomial, and their product, which is squarefree, kills T.

Proof. By the remark preceding the theorem, "T-invariant" and "$F[T]$-invariant" are the same condition, so (b) $\Leftrightarrow$ (c) is Theorem 22.3.3 applied to $A = F[T]$.

(a) $\Rightarrow$ (c). Write $m_T = p_1 \cdots p_k$ with $p_1, \dots, p_k$ distinct monic irreducibles, so that every exponent in the factorization is 1. By Theorem 8.8.1, $V = V_1 \oplus \cdots \oplus V_k$ with $V_i = \ker p_i(T)$ a non-zero T-invariant subspace on which $m_{T|_{V_i}} = p_i$.

Fix i and let $\mathbf{v} \in V_i$ with $\mathbf{v} \neq \mathbf{0}$. Then $p_i(T)\mathbf{v} = \mathbf{0}$, so the T-annihilator $m_{T,\mathbf{v}}$ divides p_i (Definition 9.5.2); it is monic of degree at least 1 because $\mathbf{v} \neq \mathbf{0}$, and p_i is irreducible, so $m_{T,\mathbf{v}} = p_i$. By Theorem 9.5.2 (a), the cyclic subspace $Z(\mathbf{v}; T)$ has dimension $\deg p_i$, and it is T-invariant (Proposition 9.5.1).

$Z(\mathbf{v}; T)$ is irreducible. Let $U \subseteq Z(\mathbf{v}; T)$ be T-invariant with $U \neq \{\mathbf{0}\}$ and pick $\mathbf{u} \in U$ with $\mathbf{u} \neq \mathbf{0}$. Since $\mathbf{u} \in V_i$, the same argument gives $m_{T,\mathbf{u}} = p_i$ and $\dim Z(\mathbf{u}; T) = \deg p_i$. As $Z(\mathbf{u}; T) \subseteq U \subseteq Z(\mathbf{v}; T)$ and the two ends have equal dimension, Theorem 1.6.8 gives $U = Z(\mathbf{v}; T)$.

Every non-zero $\mathbf{v} \in V_i$ lies in $Z(\mathbf{v}; T) \subseteq V_i$, so V_i is a sum of irreducible T-invariant subspaces, and hence so is $V = V_1 + \cdots + V_k$.

(c) $\Rightarrow$ (a). Write $V = \sum_{i \in I} W_i$ with each W_i irreducible.

Each $m_{T|_{W_i}}$ is irreducible. Pick $\mathbf{w} \in W_i$ with $\mathbf{w} \neq \mathbf{0}$. Then $Z(\mathbf{w}; T)$ is a non-zero T-invariant subspace of W_i, so $Z(\mathbf{w}; T) = W_i$, and Theorem 9.5.2 (a), (c) give $q := m_{T|_{W_i}} = m_{T,\mathbf{w}}$ with $\deg q = \dim W_i \geq 1$. Suppose q were not irreducible. Since $\deg q \geq 1$, Definition 5.3.1 then gives $q = fg$ with both f and g non-constant, and we may take them monic after dividing each by its leading coefficient. So $1 \leq \deg f < \deg q$ and $1 \leq \deg g < \deg q$. Put $\mathbf{u} = g(T)\mathbf{w}$. Then $\mathbf{u} \neq \mathbf{0}$: otherwise $g(T)\mathbf{w} = \mathbf{0}$ would give $m_{T,\mathbf{w}} \mid g$ (Definition 9.5.2), impossible since $g \neq 0$ has degree less than $\deg m_{T,\mathbf{w}}$. Also $f(T)\mathbf{u} = (fg)(T)\mathbf{w} = q(T)\mathbf{w} = \mathbf{0}$, so $m_{T,\mathbf{u}} \mid f$ and, by Theorem 9.5.2 (a), $\dim Z(\mathbf{u}; T) \leq \deg f < \dim W_i$. But $Z(\mathbf{u}; T)$ is a non-zero T-invariant subspace of W_i, hence equal to W_i by irreducibility — a contradiction. So no such factorization exists and q is irreducible.

Finitely many pieces suffice. Start with one W_{i_1}; as long as the sum of the chosen pieces is not V, some W_i is not contained in it, and adding that one strictly increases the dimension. The process stops, giving $V = W_{i_1} + \cdots + W_{i_r}$.

Conclusion. Let $q_1, \ldots, q_s$ be the distinct polynomials among $m_{T|_{W_{i_1}}}, \ldots, m_{T|_{W_{i_r}}}$ and put $q = q_1 \cdots q_s$, a product of distinct monic irreducibles. For each j, the polynomial $m_{T|_{W_{i_j}}}$ divides q, so $q(T)$ vanishes on W_{i_j}; as these subspaces span V, $q(T) = 0$ and therefore $m_T \mid q$ (Theorem 8.5.1). If some irreducible p had $p^2 \mid m_T$, then $p^2 \mid q$, which contradicts the uniqueness of the factorization of q into irreducibles (Theorem 5.3.5), every exponent there being 1. So no irreducible square divides m_T, which is (a).

■

Two things follow at once. First, the operator case is nothing but the case $A = F[T]$ of Theorem 22.3.3, so Chapter 9's vocabulary was this chapter's all along. Second, over an algebraically closed field every irreducible polynomial is linear — a monic polynomial of degree at least 2 has a root λ, hence the non-constant factor $x - \lambda$ (Theorem 5.1.3) — so "semisimple" there means "a product of distinct **linear** factors", which is diagonalizability (Theorem 8.8.2): over such a field, $F[T]$ acts semisimply on V exactly when T is diagonalizable. The shear $\mathbf{J}_2(0)$ fails on both counts, as it must. Chapter 9 §08 made a finer statement in the same direction, Proposition 9.8.2: in characteristic zero, semisimple means diagonalizable after the field has been enlarged enough to split m_T. That proposition needs its characteristic hypothesis; Theorem 22.3.7 does not, because it never leaves F.

22.3.6 Exercises

22.3.6.1 A. Check your understanding

Exercise A1.

(a) State what it means for an algebra to be **simple** and what it means for an A-space to be **irreducible**, and give one object that is the first but whose regular representation is not the second.

(b) True or false: if A acts semisimply on V, then every A-invariant subspace of V is irreducible. Justify your answer.

(c) Where exactly does the proof of Proposition 22.3.4 use the requirement $\rho(1_A) =$

id_V built into Definition 22.3.2? And why is the step $a = a1_A$ in the proof of Proposition 22.3.6 **not** an instance of that requirement?

(d) Name $\operatorname{rad} A$ for the algebra A of upper triangular 2×2 matrices, and say which two results identify it.

Solution.

(a) A is simple if $A \neq \{0\}$ and its only two-sided ideals are $\{0\}$ and A (Definition 22.3.1); an A-space V is irreducible if $V \neq \{\mathbf{0}\}$ and its only A-invariant subspaces are $\{\mathbf{0}\}$ and V (Definition 22.3.3). For $n \geq 2$ the algebra $M_n(F)$ is simple, but its regular representation is not irreducible, since the first column ideal C_1 of Example (Matrix Algebras Are Semisimple) is a proper non-zero left ideal.

(b) False. Take $A = F$ acting on $V = F^2$ by scalars. Every subspace is invariant and every subspace has a complement, so A acts semisimply; but V itself is an invariant subspace of dimension 2, and it is not irreducible.

(c) In the final paragraph, at the words "Since $1_A\mathbf{v} = \mathbf{v}$": that is the requirement $\rho(1_A) = \mathrm{id}_V$ and nothing else, and without it $\mathbf{v}$ need not lie in $A\mathbf{v}$, so V need not be the sum of the subspaces $A\mathbf{v}$. The step $a = a1_A$ in Proposition 22.3.6 is a different statement: it is axiom (A3) of Definition 13.12.1, which makes 1_A a two-sided identity of A itself, and it holds with no representation in sight.

(d) $\operatorname{rad} A = \mathcal{N}$, the strictly upper triangular matrices: the inclusion $\supseteq$ is Lemma 22.3.5 applied to the nilpotent ideal $\mathcal{N}$, and $\subseteq$ comes from the two one-dimensional representations $\mathbf{X} \mapsto x_{11}$ and $\mathbf{X} \mapsto x_{22}$.

22.3.6.2 B. Practice

Exercise B1: Which actions split?.

Determine which of the following subalgebras of $M_2(F)$, acting on $V = F^2$, act semisimply. Justify your answer in each case, and when the action is semisimple exhibit V as a direct sum of irreducibles.

(a) the scalar matrices $\{c\mathbf{I}_2 : c \in F\}$;

(b) the diagonal matrices;

(c) $F[\mathbf{N}] = \{a\mathbf{I}_2 + b\mathbf{N} : a, b \in F\}$, where $\mathbf{N} = \mathbf{J}_2(0)$;

(d) $M_2(F)$ itself.

Solution.

(a) Semisimple. Every subspace is invariant, and every subspace of a finite-dimensional space has a complement (Theorem 1.7.6). $V = F\mathbf{e}_1 \oplus F\mathbf{e}_2$, and each line is irreducible because it has dimension 1.

(b) Semisimple. By the Quick check above, the invariant subspaces are $\{\mathbf{0}\}$, $F\mathbf{e}_1$, $F\mathbf{e}_2$, F^2; the two lines are complements of each other and the two extreme cases are complements of each other. Again $V = F\mathbf{e}_1 \oplus F\mathbf{e}_2$ with both summands irreducible.

(c) Not semisimple. The invariant subspaces are the $\mathbf{N}$-invariant ones, and the only invariant line is $F\mathbf{e}_1$: if $\mathbf{v} = (x, y)$ with $y \neq 0$ then $\mathbf{N}\mathbf{v} = (y, 0)$ is a non-zero element of $F\mathbf{e}_1$, which is not a multiple of $\mathbf{v}$. So $F\mathbf{e}_1$ has no invariant complement.

(Alternatively: $m_{\mathbf{N}} = x^2$ is not squarefree, so Theorem 22.3.7 applies.)

(d) Semisimple, trivially: V is itself irreducible, as shown after Definition 22.3.3, so V is a one-term direct sum of irreducibles.

Exercise B2: A two-dimensional algebra.

Let $\mathbf{N} = \mathbf{J}_2(0) \in M_2(F)$ and $A = \{a\mathbf{I}_2 + b\mathbf{N} : a, b \in F\}$.

(a) Prove that A is a commutative subalgebra of $M_2(F)$ of dimension 2.

(b) Prove that $F\mathbf{N}$ is a two-sided ideal of A and compute $\operatorname{rad} A$.

(c) Is A a semisimple algebra? Justify your answer.

Solution.

(a) $A = \operatorname{span}(\mathbf{I}_2, \mathbf{N})$ is a subspace, and $\mathbf{I}_2, \mathbf{N}$ are independent since $\mathbf{N}$ is not a scalar. It contains $\mathbf{I}_2$, and

$$(a\mathbf{I}_2 + b\mathbf{N})(a'\mathbf{I}_2 + b'\mathbf{N}) = aa'\mathbf{I}_2 + (ab' + a'b)\mathbf{N},$$

using $\mathbf{N}^2 = \mathbf{0}$; the right-hand side lies in A and is symmetric in the two factors, so A is a commutative subalgebra of dimension 2.

(b) The displayed product shows $(a\mathbf{I}_2 + b\mathbf{N})(c\mathbf{N}) = ac\mathbf{N} \in F\mathbf{N}$, and A is commutative, so $F\mathbf{N}$ is a two-sided ideal; $(F\mathbf{N})^2 = \{0\}$ since $\mathbf{N}^2 = \mathbf{0}$. By Lemma 22.3.5, $F\mathbf{N} \subseteq \operatorname{rad} A$. Conversely $\varphi(a\mathbf{I}_2 + b\mathbf{N}) = a$ is an algebra homomorphism $A \to F$ by the same display, and $\varphi(\mathbf{I}_2) = 1$, so F is an irreducible A-space; an element of $\operatorname{rad} A$ must have $a = 0$. Hence $\operatorname{rad} A = F\mathbf{N}$.

(c) No: $\operatorname{rad} A \neq \{0\}$, so Proposition 22.3.6 rules it out.

Exercise B3: Semisimple operators.

For each of the following, decide whether $F[T]$ acts semisimply on V, using Theorem 22.3.7.

(a) $F = \mathbb{R}$, $V = \mathbb{R}^2$, T the rotation matrix $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$;

(b) $F = \mathbb{Q}$, $V = \mathbb{Q}^3$, $T = \operatorname{diag}(1, 1, 2)$;

(c) $F = \mathbb{Q}$, $V = \mathbb{Q}^3$, $T = \mathbf{J}_3(0)$;

(d) $F = \mathbb{R}$, $V = \mathbb{R}^4$, $T = \mathbf{C}\big((x^2+1)^2\big)$.

Solution.

(a) Yes. $m_T = x^2 + 1$, irreducible over $\mathbb{R}$ and occurring once, so T is semisimple. Note that T is **not** diagonalizable over $\mathbb{R}$; semisimplicity is the weaker condition.

(b) Yes. $m_T = (x-1)(x-2)$, two distinct irreducibles.

(c) No. $m_T = x^3$ repeats the irreducible x.

(d) No. $m_T = (x^2+1)^2$ by Theorem 9.5.3, and $x^2 + 1$ is repeated.

22.3.6.3 C. Going deeper

Exercise C1: The diagonal algebra.

Let $A \subseteq M_n(F)$ be the algebra of all diagonal matrices, acting on $V = F^n$.

(a) Prove that every A-invariant subspace of V is the span of a subset of $\{\mathbf{e}_1, \dots, \mathbf{e}_n\}$. *Hint: consider* $\mathbf{E}_{ii}\mathbf{v}$.

(b) Deduce that A acts semisimply on V and identify the irreducible A-subspaces.

Solution.

(a) Let U be A-invariant and put $S = \{i : u_i \neq 0 \text{ for some } \mathbf{u} \in U\}$. For $\mathbf{u} \in U$ and each i, the matrix $\mathbf{E}_{ii}$ is diagonal, so $\mathbf{E}_{ii}\mathbf{u} = u_i\mathbf{e}_i \in U$; if $i \in S$, choosing $\mathbf{u}$ with $u_i \neq 0$ gives $\mathbf{e}_i \in U$. Hence $\operatorname{span}\{\mathbf{e}_i : i \in S\} \subseteq U$. Conversely every $\mathbf{u} \in U$ is $\sum_{i \in S} u_i\mathbf{e}_i$, since $u_i = 0$ for $i \notin S$ by the definition of S. So $U = \operatorname{span}\{\mathbf{e}_i : i \in S\}$.

(b) By (a) the invariant subspaces are indexed by subsets $S \subseteq \{1, \dots, n\}$, and the complement of $\operatorname{span}\{\mathbf{e}_i : i \in S\}$ inside V given by the complementary subset is again invariant. So A acts semisimply, and $V = F\mathbf{e}_1 \oplus \cdots \oplus F\mathbf{e}_n$. The irreducible A-subspaces are exactly the coordinate lines $F\mathbf{e}_i$: they are irreducible because they have dimension 1, and by (a) no other subspace is both invariant and free of a proper non-zero invariant subspace.

Exercise C2: The radical is never everything.

Let $A \neq \{0\}$ be a finite-dimensional F-algebra.

(a) Prove that A has at least one irreducible A-space. *Hint: among the non-zero left ideals, take one of smallest dimension.*

(b) Prove that every irreducible A-space has dimension at most $\dim A$.

(c) Deduce that $1_A \notin \operatorname{rad} A$, so $\operatorname{rad} A \neq A$.

Solution.

(a) A itself is a non-zero left ideal, so among the non-zero left ideals there is one, L, of smallest dimension. A non-zero left ideal contained in L is a non-zero left ideal of A, hence has dimension at least $\dim L$, hence equals L by Theorem 1.6.8. Since the A-invariant subspaces of the regular representation are the left ideals, L is an irreducible A-space.

(b) Let V be irreducible and $\mathbf{v} \in V$ non-zero. The set $A\mathbf{v}$ is an A-invariant subspace containing $\mathbf{v} = 1_A\mathbf{v}$, so $A\mathbf{v} = V$. It is the image of the linear map $A \to V$, $a \mapsto a\mathbf{v}$, so $\dim V \leq \dim A$ by Theorem 3.3.1.

(c) Let L be as in (a). Since $L \neq \{0\}$, pick $a \in L$ with $a \neq 0$; then $1_A a = a \neq 0$, so 1_A does not act as 0 on L and therefore $1_A \notin \operatorname{rad} A$. Hence $\operatorname{rad} A \neq A$. (Note the contrast with Proposition 22.3.6: the radical is always a proper ideal, but it is $\{0\}$ only in the semisimple case.)

22.4 Schur's Lemma

Section 3 cut a space into irreducible pieces. The next question is the one that always follows a decomposition: what are the maps between the pieces? The answer is startling in its poverty — there are almost none, and the ones that exist are invertible — and that poverty is exactly what makes the rest of the chapter work. A one-line lemma will replace an unknown operator by a scalar, over and over.

The lemma has two parts, and they do **not** have the same hypotheses. The first holds over every field. The second holds only when the field is algebraically closed, and the section ends by exhibiting the failure over $\mathbb{R}$ in full. Along the way we get the explanation of why commuting operators share eigenvectors, a fact Chapter 8 proved without explaining.

Recall that a field F is **algebraically closed** if every non-constant polynomial in $F[x]$ has a root in F. The Fundamental Theorem of Algebra (Theorem 5.5.1) says $\mathbb{C}$ is one; $\mathbb{R}$ and $\mathbb{Q}$ are not, as x^2+1 and x^2-2 show. Unless a statement says otherwise, F is an arbitrary field, A is an F-algebra, and A-spaces are finite-dimensional, as in Definition 22.3.2.

22.4.1 Maps that respect the action

We have objects: A-spaces. We have subobjects: invariant subspaces. What is missing is the maps, and the requirement almost writes itself. Chapter 8 §09 got everything it had out of a single hypothesis, $ST = TS$; read S as a map and T as the action, and that hypothesis is the one below.

An A-map is a linear map for which acting and then mapping is the same as mapping and then acting.

Definition 22.4.1 — A-Map, and Isomorphism of A-spaces

Let A be an F-algebra and let V and W be A-spaces. A linear map $\varphi\colon V \to W$ is an **A-map** if

$$\varphi(a\mathbf{v}) = a\,\varphi(\mathbf{v}) \qquad \text{for every } a \in A \text{ and every } \mathbf{v} \in V.$$

We write $\mathrm{End}_A(V)$ for the set of A-maps from V to itself. A **bijective** A-map is an **isomorphism of A-spaces**, and V and W are **isomorphic** if one exists.

In words: the two actions, on the source and on the target, are tied together by φ. Note that the letter a on the left acts on V and the one on the right acts on W; the condition is a statement about two different operators. The subscript in $\mathrm{End}_A(V)$ is part of the symbol and is never dropped: the book writes $\mathcal{L}(V)$ for **all** linear maps $V \to V$, and $\mathrm{End}_A(V) \subseteq \mathcal{L}(V)$ is the subset of those that respect the action.

Three routine facts, each one line. $\mathrm{End}_A(V)$ **is a subalgebra of $\mathcal{L}(V)$ containing** id_V**:** the defining condition is linear in φ, the identity satisfies it, and if φ, ψ satisfy it then $(\varphi\psi)(a\mathbf{v}) = \varphi(a\psi(\mathbf{v})) = a(\varphi\psi)(\mathbf{v})$. **The inverse of a bijective A-map is an A-map:** given $\mathbf{w} \in W$ write $\mathbf{w} = \varphi(\mathbf{v})$; then $\varphi^{-1}(a\mathbf{w}) = \varphi^{-1}(\varphi(a\mathbf{v})) = a\mathbf{v} = a\varphi^{-1}(\mathbf{w})$. **A composite of A-maps is an A-map**, by the same computation as the first.

Examples.

- **Scalars.** $\lambda \operatorname{id}_V \in \operatorname{End}_A(V)$ for every $\lambda \in F$, since the action is linear. These are the A-maps we get for free, and Schur's lemma will say that over an algebraically closed field they are all of them.
- **The commutant, again.** If $A \subseteq \mathcal{L}(V)$ is a subalgebra containing id_V, acting tautologically, then φ is an A-map exactly when $\varphi T = T\varphi$ for every $T \in A$. So $\operatorname{End}_A(V) = A'$, the commutant of Section 1 (Definition 22.1.6, Proposition 22.1.4). The two notions are the same notion.
- **A projection onto a summand.** If $V = U \oplus W$ with both summands A-invariant, the projection of V onto U along W is an A-map: write $\mathbf{v} = \mathbf{u} + \mathbf{w}$, and $a\mathbf{v} = a\mathbf{u} + a\mathbf{w}$ is the corresponding splitting of $a\mathbf{v}$, so the projection of $a\mathbf{v}$ is $a\mathbf{u}$.

Non-example by minimal change. Take $A = F[\mathbf{N}] \subseteq \mathcal{L}(F^2)$ with $\mathbf{N} = \mathbf{J}_2(0)$, and $\varphi = \mathbf{E}_{21}$. Then $\varphi(\mathbf{N}\mathbf{e}_2) = \varphi(\mathbf{e}_1) = \mathbf{e}_2$ while $\mathbf{N}\varphi(\mathbf{e}_2) = \mathbf{N}\mathbf{0} = \mathbf{0}$. Linear, but not an A-map: the clause that fails is the displayed one, at $a = \mathbf{N}$ and $\mathbf{v} = \mathbf{e}_2$.

22.4.2 The lemma

Everything now follows from one observation: an A-map has an A-invariant kernel and an A-invariant image, and an irreducible A-space (Definition 22.3.3) has almost none of either.

Theorem 22.4.1 — Schur's Lemma

Let A be an F-algebra.

(a) Let V and W be **irreducible** A-spaces and let $\varphi\colon V \to W$ be an A-map. Then either $\varphi = 0$ or φ is an isomorphism of A-spaces. **No hypothesis on F is needed.**

(b) Suppose in addition that F is **algebraically closed**, and let V be an irreducible A-space. Then every A-map $\varphi\colon V \to V$ is a scalar: $\varphi = \lambda \operatorname{id}_V$ for some $\lambda \in F$. Equivalently, $\operatorname{End}_A(V) = \{\lambda \operatorname{id}_V : \lambda \in F\}$.

Idea. For (a): the kernel and the image are invariant, so each is one of the two extremes, and a single word — "$\varphi \neq 0$" — rules out the wrong extreme on both sides. For (b): we want to compare φ with a scalar, so we need a scalar to compare it with, and the only source of one is an eigenvalue. That is the whole role of algebraic closure. Once λ is in hand, $\varphi - \lambda \operatorname{id}_V$ is an A-map that is **not** injective, and part (a) says a non-zero one would have to be.

Proof.

(a) The kernel is A-invariant: if $\varphi(\mathbf{v}) = \mathbf{0}$ then $\varphi(a\mathbf{v}) = a\varphi(\mathbf{v}) = \mathbf{0}$. The image is A-invariant: $a\varphi(\mathbf{v}) = \varphi(a\mathbf{v}) \in \operatorname{im}\varphi$.
Suppose $\varphi \neq 0$. Then $\ker\varphi \neq V$, and since V is irreducible its only other invariant subspace is $\{\mathbf{0}\}$, so $\ker\varphi = \{\mathbf{0}\}$ and φ is injective (Theorem 3.2.3). Also $\operatorname{im}\varphi \neq \{\mathbf{0}\}$, and since W is irreducible, $\operatorname{im}\varphi = W$, so φ is surjective. Hence φ is bijective, and its inverse is an A-map by the remark above; so φ is an isomorphism of A-spaces.

(b) Since V is irreducible, $V \neq \{\mathbf{0}\}$, so $n = \dim V \geq 1$ and the characteristic polynomial p_φ is monic of degree n, hence non-constant. As F is algebraically closed, p_φ

has a root $\lambda \in F$, and λ is then an eigenvalue of φ (Theorem 8.2.1).

Put $\psi = \varphi - \lambda\,\mathrm{id}_V$. It is an A-map, because $\mathrm{End}_A(V)$ is a subspace containing id_V. Its kernel is $E_\lambda(\varphi) \neq \{\mathbf{0}\}$, so ψ is not injective and therefore not an isomorphism. By (a), applied with $W = V$, the only remaining possibility is $\psi = 0$, that is, $\varphi = \lambda\,\mathrm{id}_V$. Conversely every scalar multiple of id_V is an A-map, so $\mathrm{End}_A(V)$ consists exactly of these. This proves the lemma.

■

Part (a) says something worth naming even when the field is small: for an irreducible V, every non-zero element of $\mathrm{End}_A(V)$ is invertible. An algebra with that property is called a **division algebra**, and part (a) is the statement that the commutant of an irreducible action is one. Part (b) says that over an algebraically closed field the only division algebra that can occur is F itself. That is a genuine restriction on the field, not a formality.

Warning. **Only the second part needs algebraic closure.** Part (a) was proved over an arbitrary field and will be used over arbitrary fields. Part (b) used exactly one thing that (a) did not: the existence of an eigenvalue of φ. Quoting "Schur's lemma says the commutant is the scalars" without the hypothesis is the standard error, and the next example is the standard witness.

22.4.3 What goes wrong over the reals

Example. (A Real Irreducible Representation with Commutant $\mathbb{C}$)

Let $n \geq 3$, put $\theta = 2\pi/n$, $c = \cos\theta$, $s = \sin\theta$, and let

$$\mathbf{R} = \begin{pmatrix} c & -s \\ s & c \end{pmatrix} \in M_2(\mathbb{R}).$$

Since $\mathbf{R}^n = \mathbf{I}_2$, the powers of $\mathbf{R}$ repeat with period dividing n; Section 7 will read $k \mapsto \mathbf{R}^k$ as a representation of a cyclic group, and that is what we will then call the **rotation representation**. Let $A = \mathbb{R}[\mathbf{R}] \subseteq M_2(\mathbb{R})$ be the algebra of polynomials in $\mathbf{R}$, so that the A-invariant subspaces of $\mathbb{R}^2$ are exactly the $\mathbf{R}$-invariant ones. Show that $\mathbb{R}^2$ is an irreducible A-space and compute $\mathrm{End}_A(\mathbb{R}^2)$.

Solution. **Irreducible.** A proper non-zero invariant subspace of $\mathbb{R}^2$ would be a line $\mathbb{R}\mathbf{v}$ with $\mathbf{R}\mathbf{v} \in \mathbb{R}\mathbf{v}$, that is, a real eigenvector of $\mathbf{R}$. Now

$$p_{\mathbf{R}}(x) = x^2 - 2cx + 1,$$

whose discriminant is $4c^2 - 4 = -4s^2$. For $n \geq 3$ we have $0 < \theta \leq 2\pi/3 < \pi$, so $s = \sin\theta > 0$ and the discriminant is negative: $p_{\mathbf{R}}$ has no real root, hence $\mathbf{R}$ has no real eigenvalue (Theorem 8.2.1), hence no invariant line. So the only invariant subspaces are $\{\mathbf{0}\}$ and $\mathbb{R}^2$, and $\mathbb{R}^2 \neq \{\mathbf{0}\}$.

The commutant. Since A acts tautologically, $\mathrm{End}_A(\mathbb{R}^2)$ is the commutant A' (Definition 22.1.6): the set of $\mathbf{X} \in M_2(\mathbb{R})$ commuting with every element of A; since A consists of polynomials in $\mathbf{R}$, this is the set of $\mathbf{X}$ with $\mathbf{X}\mathbf{R} = \mathbf{R}\mathbf{X}$. Write $\mathbf{X} = \left(\begin{smallmatrix} p & q \\ r & t \end{smallmatrix}\right)$. Multiplying

out,

$$\mathbf{XR} = \begin{pmatrix} pc+qs & -ps+qc \\ rc+ts & -rs+tc \end{pmatrix},$$
$$\mathbf{RX} = \begin{pmatrix} cp-sr & cq-st \\ sp+cr & sq+ct \end{pmatrix},$$

so that

$$\mathbf{XR}-\mathbf{RX} = s\begin{pmatrix} q+r & t-p \\ t-p & -(q+r) \end{pmatrix}.$$

Since $s \neq 0$, the equation $\mathbf{XR} = \mathbf{RX}$ says exactly $r = -q$ and $t = p$. Writing $\mathbf{Q} = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ for the quarter turn, we get

$$\mathrm{End}_A(\mathbb{R}^2) = \{\, p\mathbf{I}_2 + r\mathbf{Q} : p, r \in \mathbb{R} \,\},$$

a two-dimensional real algebra. It is a copy of $\mathbb{C}$: the map $p + ri \mapsto p\mathbf{I}_2 + r\mathbf{Q}$ is linear and bijective (it carries the basis $1, i$ to the independent $\mathbf{I}_2, \mathbf{Q}$), it sends 1 to $\mathbf{I}_2$, and since $\mathbf{Q}^2 = -\mathbf{I}_2$,

$$(p\mathbf{I}_2 + r\mathbf{Q})(p'\mathbf{I}_2 + r'\mathbf{Q}) = (pp' - rr')\mathbf{I}_2 + (pr' + rp')\mathbf{Q},$$

which matches $(p + ri)(p' + r'i) = (pp' - rr') + (pr' + rp')i$. So it is an isomorphism of $\mathbb{R}$-algebras.

What this shows. Part (b) of Theorem 22.4.1 fails over $\mathbb{R}$: here $\mathrm{End}_A(\mathbb{R}^2)$ has dimension 2, not 1. Part (a) does not fail, and we can see it directly: $\det(p\mathbf{I}_2 + r\mathbf{Q}) = p^2 + r^2$, which is non-zero unless $p = r = 0$, so every non-zero element of the commutant is invertible, exactly as (a) predicts. The commutant is a division algebra; it is just not $\mathbb{R}$.

Remark. The same computation with $n = 4$ gives $\mathbf{R} = \mathbf{Q}$, and the commutant $\mathbb{R}[\mathbf{Q}]$ is then the algebra generated by $\mathbf{R}$ itself. Over $\mathbb{C}$ the picture collapses: $\mathbf{R}$ has eigenvalues $e^{\pm i\theta}$ there, so the two eigenlines are invariant and $\mathbb{C}^2$ is **not** an irreducible $\mathbb{C}[\mathbf{R}]$-space. Irreducibility, like semisimplicity, is a statement about a space **and** a field.

22.4.4 Families of operators

The corollaries below are about a family of operators — a set of matrices, the image of a group — rather than about an algebra given in advance. The translation costs one lemma, and Section 1's generated subalgebra is what it produces.

Lemma 22.4.2 — A Family and the Algebra It Generates

Let V be a finite-dimensional vector space over F and let $\mathcal{F} \subseteq \mathcal{L}(V)$ be any set of operators. Write $A(\mathcal{F}) := F\langle\mathcal{F}\rangle$ for the subalgebra of $\mathcal{L}(V)$ generated by $\mathcal{F}$ (Definition 22.1.4). Then:

(a) $A(\mathcal{F})$ contains $\mathcal{F}$ and id_V, and is the span of id_V together with all products $S_1 S_2 \cdots S_m$ with $m \geq 1$ and $S_1, \ldots, S_m \in \mathcal{F}$;

(b) a subspace $U \subseteq V$ is invariant under every member of $\mathcal{F}$ if and only if it is $A(\mathcal{F})$-invariant;

(c) an operator $S \in \mathcal{L}(V)$ commutes with every member of $\mathcal{F}$ if and only if it commutes with every element of $A(\mathcal{F})$;

(d) if the members of $\mathcal{F}$ commute with one another, then $A(\mathcal{F})$ is commutative.

Proof.

(a) A generated subalgebra contains its generators, and every subalgebra contains the identity (Definition 22.1.1), which in $\mathcal{L}(V)$ is id_V. The span description is Proposition 22.1.1 applied to the set $\mathcal{F}$ inside the algebra $\mathcal{L}(V)$.

(b) ($\Leftarrow$) holds because $\mathcal{F} \subseteq A(\mathcal{F})$. ($\Rightarrow$) If $SU \subseteq U$ for every $S \in \mathcal{F}$, then applying the members one at a time gives $S_1 \cdots S_m U \subseteq U$ for every word, and $\mathrm{id}_V U \subseteq U$; a subspace is closed under linear combinations, so $A(\mathcal{F})U \subseteq U$.

(c) ($\Leftarrow$) again holds because $\mathcal{F} \subseteq A(\mathcal{F})$. ($\Rightarrow$) If S commutes with each S_i then it commutes with $S_1 \cdots S_m$, by moving S across one factor at a time; it commutes with id_V; and the set of operators commuting with S is a subspace, so it contains the span.

(d) Let $S \in \mathcal{F}$. By hypothesis S commutes with every member of $\mathcal{F}$, so by (c) it commutes with every element of $A(\mathcal{F})$. Now fix $a \in A(\mathcal{F})$. What we have just shown says that every member of $\mathcal{F}$ commutes with a; applying (c) to a in place of S, the element a commutes with every element of $A(\mathcal{F})$. As a was arbitrary, $A(\mathcal{F})$ is commutative.

■

Say that a family $\mathcal{F} \subseteq \mathcal{L}(V)$ **acts irreducibly** if $V \neq \{\mathbf{0}\}$ and the only subspaces invariant under every member of $\mathcal{F}$ are $\{\mathbf{0}\}$ and V. By (a) and (b), this says exactly that V is an irreducible $A(\mathcal{F})$-space.

Corollary 22.4.3 — An Operator Commuting with an Irreducible Family Is a Scalar

Let F be **algebraically closed**, let V be a finite-dimensional vector space over F, and let $\mathcal{F} \subseteq \mathcal{L}(V)$ act irreducibly. If $S \in \mathcal{L}(V)$ commutes with every member of $\mathcal{F}$, then $S = \lambda\,\mathrm{id}_V$ for some $\lambda \in F$.

Proof. Put $A = A(\mathcal{F})$, a subalgebra of $\mathcal{L}(V)$ containing id_V by Lemma 22.4.2 (a), so V is an A-space under the tautological representation, and by (b) it is irreducible. By (c), S commutes with every element of A, that is, $S \in \mathrm{End}_A(V)$. Since F is algebraically closed, Theorem 22.4.1 (b) gives $S = \lambda\,\mathrm{id}_V$.

■

Corollary 22.4.4 — Over an Algebraically Closed Field, Commutative Means One-Dimensional

Let F be **algebraically closed**, let A be a **commutative** F-algebra, and let V be an irreducible A-space. Then $\dim V = 1$.

Idea. Commutativity makes every operator of the action an A-map, so Schur turns all of them into scalars at once. But an algebra of scalars leaves every subspace invariant, and only a line can survive that.

Proof. Let $a \in A$. For every $b \in A$ we have $\rho(a)\rho(b) = \rho(ab) = \rho(ba) = \rho(b)\rho(a)$, so $\rho(a)$ is an A-map from V to itself. By Theorem 22.4.1 (b) there is $\lambda(a) \in F$ with $\rho(a) = \lambda(a)\,\mathrm{id}_V$.

Hence $a\mathbf{v} = \lambda(a)\mathbf{v}$ for every $a \in A$ and $\mathbf{v} \in V$, so **every** subspace of V is A-invariant. Since V is irreducible, $V \neq \{\mathbf{0}\}$; pick $\mathbf{v} \neq \mathbf{0}$. Then $F\mathbf{v}$ is a non-zero A-invariant subspace, so $F\mathbf{v} = V$ and $\dim V = 1$.

■

Both hypotheses are doing work. Commutativity is needed: $\mathbb{C}^2$ is an irreducible $M_2(\mathbb{C})$-space of dimension 2. Algebraic closure is needed: in Example (A Real Irreducible Representation with Commutant $\mathbb{C}$) the algebra $A = \mathbb{R}[\mathbf{R}]$ is commutative, being generated by one operator, and $\mathbb{R}^2$ is an irreducible A-space of dimension 2.

Quick check. The algebra $A = \mathbb{R}[\mathbf{R}]$ of Example (A Real Irreducible Representation with Commutant $\mathbb{C}$) is commutative and $\mathbb{R}^2$ is an irreducible A-space of dimension 2. Which hypothesis of Corollary 22.4.4 fails, and where exactly does the proof break?

Solution. Algebraic closure fails: $\mathbb{R}$ is not algebraically closed. The proof breaks at its first move, the appeal to Theorem 22.4.1 (b): the operator $\rho(\mathbf{R}) = \mathbf{R}$ is indeed an A-map, but it is not a scalar, because its characteristic polynomial $x^2 - 2cx + 1$ has no root in $\mathbb{R}$ and so $\mathbf{R}$ has no eigenvalue to be a scalar multiple of. Everything before that point — commutativity, irreducibility, the fact that each $\rho(a)$ is an A-map — is still true.

Section 9 will use Corollary 22.4.4 in exactly the form stated: over $\mathbb{C}$, every irreducible representation of a commutative algebra, and hence of an abelian group, is one-dimensional, so its "matrix" is a single complex number.

22.4.5 Looking back at commuting operators

Chapter 8 §09 proved that a commuting family of operators, each with a splitting characteristic polynomial, has a common eigenvector (Theorem 8.9.3), and built simultaneous diagonalization on it. At the time the proof looked like a clever trick: take a minimal invariant subspace and show every operator is a scalar on it. We can now say what the trick was.

Corollary 22.4.5 — Commuting Operators Have a Common Eigenvector

Let F be **algebraically closed**, let $V \neq \{\mathbf{0}\}$ be finite-dimensional over F, and let $\mathcal{F} \subseteq \mathcal{L}(V)$ be a family whose members commute with one another. Then there is $\mathbf{v} \neq \mathbf{0}$ that is an eigenvector of every $T \in \mathcal{F}$.

Proof. Among the non-zero subspaces of V invariant under every member of $\mathcal{F}$ — there is one, namely V — choose W of smallest dimension. Put $A = A(\mathcal{F})$, which is a commutative subalgebra of $\mathcal{L}(V)$ containing id_V by Lemma 22.4.2 (a), (d), and note that W is A-invariant by part (b) of the same lemma. So $a \mapsto a|_W$ is a representation of A on W.

W is an irreducible A-space: it is non-zero, and a non-zero A-invariant subspace $U \subseteq W$ is, by Lemma 22.4.2 (b), invariant under every member of $\mathcal{F}$, hence has $\dim U \geq \dim W$ by the choice of W, hence equals W (Theorem 1.6.8).

By Corollary 22.4.4, $\dim W = 1$. Write $W = F\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$. For every $T \in \mathcal{F}$ we have $T\mathbf{v} \in W = F\mathbf{v}$, so $\mathbf{v}$ is an eigenvector of T. This proves the corollary.

■

That is Chapter 8's argument, with its steps given their names: "minimal non-zero invariant subspace" is "irreducible", and "every operator is a scalar on it" is Schur's lemma. The version proved there is the stronger one — it asks only that each p_T split over F, not that F be algebraically closed — and getting that extra generality is exactly what its Lemma 8.9.2 was for. What this section adds is not strength but explanation: the scalars appeared because a commutative algebra acting irreducibly over an algebraically closed field has nowhere to act except on a line.

The other half of Chapter 8 §09, simultaneous diagonalization, needs one more ingredient: that the whole space splits into such lines, not just that one of them exists. Section 3's language names that ingredient — the algebra must act semisimply — and in the presence of an inner product it comes for free.

Proposition 22.4.6 — Closed Under Adjoints Implies Semisimple

Let V be a finite-dimensional inner product space over $F = \mathbb{R}$ or $F = \mathbb{C}$, and let $A \subseteq \mathcal{L}(V)$ be a subalgebra containing id_V and closed under adjoints: $T \in A$ implies $T^* \in A$ (Definition 10.6.1). Then:

(a) for every A-invariant subspace U, the orthogonal complement $U^\perp$ is A-invariant, and $V = U \oplus U^\perp$; in particular A acts semisimply on V;

(b) V is a direct sum of **pairwise orthogonal** irreducible A-invariant subspaces.

Proof.

(a) Let U be A-invariant, let $T \in A$ and $\mathbf{w} \in U^\perp$. For every $\mathbf{u} \in U$,

$$\langle T\mathbf{w}, \mathbf{u} \rangle = \langle \mathbf{w}, T^*\mathbf{u} \rangle = 0,$$

because $T^* \in A$ gives $T^*\mathbf{u} \in U$, while $\mathbf{w} \in U^\perp$. So $T\mathbf{w} \in U^\perp$, and $U^\perp$ is A-invariant. The splitting $V = U \oplus U^\perp$ is Theorem 10.3.2 (a). Hence every A-invariant subspace has an A-invariant complement (Definition 22.3.4).

(b) Induction on $\dim V$. If $V = \{\mathbf{0}\}$ it is the empty direct sum. Otherwise choose, among the non-zero A-invariant subspaces, one of smallest dimension, W; as in the proof of Theorem 22.3.3 it is irreducible. By (a), $V = W \oplus W^\perp$ with $W^\perp$ invariant and $\dim W^\perp < \dim V$.

The restricted algebra $A|_{W^\perp} = \{T|_{W^\perp} : T \in A\} \subseteq \mathcal{L}(W^\perp)$ satisfies the same hypotheses on the inner product space $W^\perp$: it is a subalgebra containing $\mathrm{id}_{W^\perp}$, and for $\mathbf{w}, \mathbf{w}' \in W^\perp$,

$$\langle T|_{W^\perp}\mathbf{w}, \mathbf{w}'\rangle = \langle T\mathbf{w}, \mathbf{w}'\rangle = \langle \mathbf{w}, T^*\mathbf{w}'\rangle = \langle \mathbf{w}, T^*|_{W^\perp}\mathbf{w}'\rangle,$$

so $(T|_{W^\perp})^* = T^*|_{W^\perp} \in A|_{W^\perp}$ by uniqueness of the adjoint (Theorem 10.6.1). By the inductive hypothesis $W^\perp = W_1 \oplus \cdots \oplus W_r$ with the W_i pairwise orthogonal and irreducible, and each $W_i \subseteq W^\perp$ is orthogonal to W. Hence $V = W \oplus W_1 \oplus \cdots \oplus W_r$ as required.

■

Now take a commuting family $\mathcal{F}$ of **self-adjoint** operators on a finite-dimensional complex inner product space $V \neq \{\mathbf{0}\}$, and put $A = A(\mathcal{F})$. It is commutative by Lemma 22.4.2 (d). It is closed under adjoints, because $(S_1 \cdots S_m)^* = S_m^* \cdots S_1^* = S_m \cdots S_1 = S_1 \cdots S_m$, the last step by commutativity, and because $\varphi \mapsto \varphi^*$ is conjugate-linear, so the span of a set of self-adjoint operators is closed under it. By Proposition 22.4.6, V is an orthogonal direct sum of irreducible A-subspaces; by Corollary 22.4.4 those subspaces are lines; and a line invariant under every member of $\mathcal{F}$ is spanned by a common eigenvector. Normalizing gives an orthonormal basis of common eigenvectors — Chapter 11 §07's conclusion (Theorem 11.7.1) for a commuting self-adjoint family, obtained here by putting two general facts together rather than by an induction tailored to the situation. Chapter 11 proves more, for commuting **normal** families, and pays for it with a longer argument.

Warning. **The converse of Corollary 22.4.3 is false.** A family whose commutant is only the scalars need not act irreducibly, and the witness is short. Take $F = \mathbb{C}$ and let $\mathcal{F}$ be the algebra of upper triangular matrices in $M_2(\mathbb{C})$, acting on $\mathbb{C}^2$. A matrix commuting with $\mathbf{E}_{11}$ must be diagonal, and one commuting with $\mathbf{E}_{12}$ as well must have equal diagonal entries, so the commutant is $\{p\mathbf{I}_2 : p \in \mathbb{C}\}$, the scalars; exercise C2 does the two computations. Yet $\mathbb{C}\mathbf{e}_1$ is invariant under every upper triangular matrix, so $\mathcal{F}$ does not act irreducibly. Thus "the commutant is the scalars" is a consequence of irreducibility, never a test for it. The genuine converse statement, that an irreducible subalgebra is **all** of $\mathcal{L}(V)$, is Burnside's theorem in Section 5, and it needs more than the commutant.

22.4.6 Exercises

22.4.6.1 A. Check your understanding

Exercise A1.

(a) State both parts of Schur's lemma and say precisely which one needs F to be algebraically closed, and what that hypothesis is used for.

(b) True or false: if V and W are irreducible A-spaces with $\dim V \neq \dim W$, then the only A-map $V \to W$ is 0. Justify your answer.

(c) Explain why, for an irreducible A-space V, no element of $\mathrm{End}_A(V)$ can be non-zero and non-invertible.

(d) Give $\mathrm{End}_A(\mathbb{R}^2)$ for the rotation representation of Example (A Real Irreducible

Representation with Commutant $\mathbb{C}$), and say which part of Schur's lemma it illustrates and which it refutes.

Solution.

(a) Part (a): an A-map between irreducible A-spaces is 0 or an isomorphism; no hypothesis on F. Part (b): over an algebraically closed F, every A-map from an irreducible V to itself is a scalar. Algebraic closure is used once, to produce a root of the characteristic polynomial of φ, that is, an eigenvalue.

(b) True. A non-zero A-map would be an isomorphism by Theorem 22.4.1 (a), and an isomorphism of vector spaces preserves dimension (Theorem 3.5.4), contradicting $\dim V \neq \dim W$.

(c) By Theorem 22.4.1 (a) with $W = V$: a non-zero A-map $V \to V$ is an isomorphism, hence invertible.

(d) $\mathrm{End}_A(\mathbb{R}^2) = \{p\mathbf{I}_2 + r\mathbf{Q}\} \cong \mathbb{C}$. It illustrates part (a) — every non-zero element has determinant $p^2 + r^2 \neq 0$, so the commutant is a division algebra — and refutes part (b) read without its hypothesis, since the commutant is two-dimensional over $\mathbb{R}$.

22.4.6.2 B. Practice

Exercise B1: An irreducibility test.

Let $\mathbf{D} = \mathrm{diag}(i, -i) \in M_2(\mathbb{C})$, which satisfies $\mathbf{D}^4 = \mathbf{I}_2$, and let $A = \mathbb{C}[\mathbf{D}]$ be the algebra of polynomials in $\mathbf{D}$.

(a) Compute $\mathrm{End}_A(\mathbb{C}^2)$.

(b) Deduce from Theorem 22.4.1 (b) that $\mathbb{C}^2$ is not an irreducible A-space, and confirm this by exhibiting a proper non-zero invariant subspace.

Solution.

(a) An operator is an A-map exactly when it commutes with $\mathbf{D}$, since the elements of A are the polynomials in $\mathbf{D}$. Writing $\mathbf{X} = \left(\begin{smallmatrix} p & q \\ r & t \end{smallmatrix}\right)$,

$$\mathbf{XD} - \mathbf{DX} = \begin{pmatrix} 0 & -2iq \\ 2ir & 0 \end{pmatrix},$$

which vanishes exactly when $q = r = 0$. So $\mathrm{End}_A(\mathbb{C}^2)$ is the algebra of diagonal matrices, of dimension 2.

(b) If $\mathbb{C}^2$ were irreducible then, $\mathbb{C}$ being algebraically closed, Theorem 22.4.1 (b) would force $\mathrm{End}_A(\mathbb{C}^2)$ to have dimension 1. It has dimension 2, so $\mathbb{C}^2$ is not irreducible. Indeed $\mathbb{C}\mathbf{e}_1$ is invariant, since $\mathbf{De}_1 = i\mathbf{e}_1$.

Exercise B2: The quarter turn, over two fields.

Let $\mathbf{Q} = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, the rotation by a quarter turn, and let $A_F = F[\mathbf{Q}]$ for $F = \mathbb{R}$ and for $F = \mathbb{C}$.

(a) Show that $\mathbb{R}^2$ is an irreducible $A_{\mathbb{R}}$-space and that $\mathrm{End}_{A_{\mathbb{R}}}(\mathbb{R}^2) \cong \mathbb{C}$.

(b) Show that $\mathbb{C}^2$ is **not** an irreducible $A_{\mathbb{C}}$-space, and find two invariant lines.

(c) Explain why (a) and (b) together are consistent with Schur's lemma.

Solution.

(a) This is Example (A Real Irreducible Representation with Commutant $\mathbb{C}$) with $n = 4$, so $\theta = \pi/2$, $c = 0$, $s = 1$: the characteristic polynomial $x^2 + 1$ has no real root, so there is no invariant line and $\mathbb{R}^2$ is irreducible; and the commutant is $\{p\mathbf{I}_2 + r\mathbf{Q}\} \cong \mathbb{C}$.

(b) Over $\mathbb{C}$ the polynomial $x^2 + 1$ has the roots $\pm i$, so $\mathbf{Q}$ has eigenvalues i and $-i$, with eigenvectors $(1, -i)$ and $(1, i)$ respectively: from $\mathbf{Q}(1, -i) = (i, 1) = i(1, -i)$ and $\mathbf{Q}(1, i) = (-i, 1) = -i(1, i)$. Each of $\mathbb{C}(1, i)$ and $\mathbb{C}(1, -i)$ is a proper non-zero invariant line.

(c) Part (b) of Schur's lemma applies only over an algebraically closed field. Over $\mathbb{C}$ it does apply, and it is not contradicted: the space is reducible there, so the lemma says nothing about it. Over $\mathbb{R}$ the space is irreducible but the field is not algebraically closed, so only part (a) applies — and part (a) holds, since every non-zero element of $\{p\mathbf{I}_2 + r\mathbf{Q}\}$ is invertible.

Exercise B3: A common eigenvector.

Let

$$\mathbf{A} = \begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 3 & 5 \\ 0 & 3 \end{pmatrix} \in M_2(\mathbb{C}).$$

(a) Verify that $\mathbf{AB} = \mathbf{BA}$.

(b) Find a common eigenvector, and check that it spans the unique minimal non-zero invariant subspace, as in the proof of Corollary 22.4.5.

Solution.

(a) The diagonal entries of both products are $2 \cdot 3 = 6$, the lower left entry of both is 0, and the upper right entries are $(\mathbf{AB})_{12} = 2 \cdot 5 + 1 \cdot 3 = 13$ and $(\mathbf{BA})_{12} = 3 \cdot 1 + 5 \cdot 2 = 13$. So

$$\mathbf{AB} = \mathbf{BA} = \begin{pmatrix} 6 & 13 \\ 0 & 6 \end{pmatrix}.$$

(b) $\mathbf{A}\mathbf{e}_1 = 2\mathbf{e}_1$ and $\mathbf{B}\mathbf{e}_1 = 3\mathbf{e}_1$, so $\mathbf{e}_1$ is a common eigenvector and $\mathbb{C}\mathbf{e}_1$ is invariant. It is the only invariant line: if $\mathbf{v} = (x, y)$ with $y \neq 0$ spanned an invariant line, then $\mathbf{A}\mathbf{v} = (2x + y, 2y)$ would be a multiple $c\mathbf{v}$, forcing $c = 2$ from the second coordinate and then $y = 0$ from the first. So $\mathbb{C}\mathbf{e}_1$ is the minimal non-zero invariant subspace the proof of Corollary 22.4.5 produces, and it is a line, as Corollary 22.4.4 requires.

22.4.6.3 C. Going deeper

Exercise C1: A commutant that is a field.

Let $\mathbf{A} = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right) \in M_2(\mathbb{Q})$, the companion matrix of $x^2 - 2$, and let $A = \mathbb{Q}[\mathbf{A}]$.

(a) Prove that $\mathbb{Q}^2$ is an irreducible A-space.

(b) Compute $\mathrm{End}_A(\mathbb{Q}^2)$ and prove that it is a field in which 2 has a square root.

(c) Explain why this does not contradict Theorem 22.4.1.

Solution.

(a) $p_{\mathbf{A}} = x^2 - 2$ by Theorem 9.5.3, and $x^2 - 2$ has no rational root, since $\sqrt{2}$ is irrational (Theorem 0.2.3). So $\mathbf{A}$ has no eigenvalue in $\mathbb{Q}$ (Theorem 8.2.1), hence no invariant line, and the only invariant subspaces of $\mathbb{Q}^2$ are $\{\mathbf{0}\}$ and $\mathbb{Q}^2$.

(b) An A-map is an $\mathbf{X} = \left(\begin{smallmatrix} p & q \\ r & t \end{smallmatrix}\right)$ commuting with $\mathbf{A}$. Computing,

$$\mathbf{XA} - \mathbf{AX} = \begin{pmatrix} q - 2r & 2p - 2t \\ t - p & 2r - q \end{pmatrix},$$

which vanishes exactly when $t = p$ and $q = 2r$. So

$$\mathrm{End}_A(\mathbb{Q}^2) = \{\, p\mathbf{I}_2 + r\mathbf{A} : p, r \in \mathbb{Q} \,\},$$

using $\mathbf{A} = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$. Since $\mathbf{A}^2 = 2\mathbf{I}_2$, this is a commutative algebra in which $\mathbf{A}$ is a square root of $2\mathbf{I}_2$; and every non-zero element is invertible, because $\det(p\mathbf{I}_2 + r\mathbf{A}) = p^2 - 2r^2$, which vanishes for rational p, r only when $p = r = 0$: if $r = 0$ then $p^2 = 0$, and if $r \neq 0$ then $(p/r)^2 = 2$ with $p/r \in \mathbb{Q}$, contradicting Theorem 0.2.3. A commutative algebra in which every non-zero element is invertible is a field.

(c) Part (a) of Theorem 22.4.1 predicts exactly this: the commutant of an irreducible action is a division algebra. Part (b) does not apply, because $\mathbb{Q}$ is not algebraically closed.

Exercise C2: Scalar commutant without irreducibility.

Let F be **algebraically closed** — say $F = \mathbb{C}$, so that Corollary 22.4.3 really applies — and let $A \subseteq M_2(F)$ be the algebra of upper triangular matrices.

(a) Compute the set of $\mathbf{X} \in M_2(F)$ commuting with every element of A. (The computation uses nothing about F.)

(b) Deduce that the converse of Corollary 22.4.3 fails: a family with commutant the scalars need not act irreducibly.

Solution.

(a) It suffices to commute with the basis $\mathbf{E}_{11}, \mathbf{E}_{12}, \mathbf{E}_{22}$. Write $\mathbf{X} = \left(\begin{smallmatrix} p & q \\ r & t \end{smallmatrix}\right)$. From

$$\mathbf{XE}_{11} - \mathbf{E}_{11}\mathbf{X} = \begin{pmatrix} 0 & -q \\ r & 0 \end{pmatrix}$$

we get $q = r = 0$, and then

$$\mathbf{XE}_{12} - \mathbf{E}_{12}\mathbf{X} = \begin{pmatrix} 0 & p - t \\ 0 & 0 \end{pmatrix}$$

gives $p = t$. Conversely a scalar matrix commutes with everything. So the commutant is $\{p\mathbf{I}_2 : p \in F\}$, the scalars.

(b) The family $\mathcal{F} = A$ has commutant the scalars by (a), yet it does not act irreducibly on F^2: the line $F\mathbf{e}_1$ is invariant, as computed in Example (Upper Triangular Matrices Are Not Semisimple). So the implication in Corollary 22.4.3 cannot be reversed. (The hypothesis is not vacuous either: over an algebraically closed field the corollary does apply whenever the family is irreducible.)

22.5 Burnside and the Double Commutant

Twice already the book has computed a commutant: Chapter 9 §04 found the matrices commuting with a basic Weyr matrix, and Chapter 11 §10 found the matrices commuting with a block diagonal matrix whose blocks have separated spectra. Both times the question was *given one operator, who commutes with it?* This section turns the question round. Given a whole algebra of operators, how much of the algebra can be read off from its commutant, and when is the algebra as large as it could possibly be? Two theorems answer this. Burnside's theorem says that over an algebraically closed field an algebra with no invariant subspace to hide in must be everything; the double commutant theorem says that a semisimple algebra is exactly the set of operators commuting with everything that commutes with it.

Throughout, V is a finite-dimensional vector space over a field F, and $\mathrm{End}(V)$ is the space $\mathcal{L}(V)$ of operators regarded as an algebra under composition. A **subalgebra** $A \subseteq \mathrm{End}(V)$ contains id_V by (SA3) of Definition 22.1.1; this is not decoration, and the warning after Theorem 22.5.5 shows what goes wrong without it.

22.5.1 Commutants, and when an operator is a scalar

For a subalgebra $A \subseteq \mathrm{End}(V)$, Definition 22.1.6 sets

$$A' = \{t \in \mathrm{End}(V) : ta = at \text{ for all } a \in A\},$$

and Proposition 22.1.4 says A' is again a subalgebra containing id_V.

Applying the prime twice gives the **double commutant** $A'' := (A')'$. One inclusion is free and worth recording at once: by Proposition 22.1.4 (c),

$$A \subseteq A''.$$

The content of this section is that the reverse inclusion holds under a hypothesis we can name exactly.

Both theorems below end by proving that some operator is a scalar, and §01 has already supplied the fact that lets us conclude this. By Proposition 22.1.5 the center of $M_n(F)$ consists of the scalar matrices or, in the operator form recorded there, for a finite-dimensional $V \neq \{\mathbf{0}\}$ the operators commuting with every operator on V are exactly the scalar multiples of id_V:

$$\mathrm{End}(V)' = \{\lambda\,\mathrm{id}_V : \lambda \in F\}.$$

Nothing new is proved here; it is the operator form that the proofs below call on.

22.5.2 Algebras that act irreducibly

Recall from §03 that V is **irreducible** as an A-space (§03 calls such a space simple, Definition 22.3.3) when $V \neq \{\mathbf{0}\}$ and the only A-invariant subspaces of V are $\{\mathbf{0}\}$ and V. The following one-line consequence is used in every proof of this section, so we isolate it.

Lemma 22.5.1 — An Irreducible Algebra Moves One Vector Everywhere

Let $A \subseteq \mathrm{End}(V)$ be a subalgebra with $\mathrm{id}_V \in A$, acting irreducibly on V. Then $A\mathbf{v} := \{a\mathbf{v} : a \in A\} = V$ for every $\mathbf{v} \neq \mathbf{0}$.

Proof. The set $A\mathbf{v}$ is the image of the linear map $A \to V$, $a \mapsto a\mathbf{v}$, hence a subspace. It is A-invariant: $b(a\mathbf{v}) = (ba)\mathbf{v} \in A\mathbf{v}$ for $b \in A$, since $ba \in A$. It contains $\mathrm{id}_V\,\mathbf{v} = \mathbf{v} \neq \mathbf{0}$, so it is not $\{\mathbf{0}\}$. Irreducibility leaves only $A\mathbf{v} = V$. ∎

Warning. **The assumption $\mathrm{id}_V \in A$ is doing real work here.** Take $V = F$, a line, and $A = \{0\}$, a subspace closed under composition but not a subalgebra, since it does not contain id_V. The only subspaces of V at all are $\{\mathbf{0}\}$ and V, so A satisfies the letter of irreducibility, yet $A\mathbf{v} = \{\mathbf{0}\} \neq V$ and $A \neq \mathrm{End}(V) = F$. Every statement below about an algebra acting irreducibly assumes the identity belongs to the algebra.

22.5.3 Burnside's theorem

Here is the question. An algebra $A \subseteq \mathrm{End}(V)$ that acts irreducibly has nowhere to hide: no proper non-zero subspace survives it. Does that force A to be all of $\mathrm{End}(V)$? Over $\mathbb{C}$ the answer is yes. The proof is worth the trouble: the corollary below, which says that an irreducibly acting **set** of operators already spans $\mathrm{End}(V)$, is what the representation theory later in this chapter uses to turn statements about a group into statements about all matrices.

Theorem 22.5.2 — Burnside's Theorem

Let F be an **algebraically closed** field, that is, one in which every non-constant polynomial in $F[x]$ has a root. Let V be a vector space over F with $1 \leq \dim V < \infty$, and let $A \subseteq \mathrm{End}(V)$ be a subalgebra with $\mathrm{id}_V \in A$. If V is irreducible as an A-space, then

$$A = \mathrm{End}(V).$$

Idea. **Step roadmap.** ① Among the non-zero members of A, let r be the smallest rank, attained at a. ② Show $r = 1$. If $r \geq 2$, the image $\mathrm{im}\,a$ has two independent vectors $a\mathbf{u}_1, a\mathbf{u}_2$, and irreducibility supplies $b \in A$ carrying $a\mathbf{u}_1$ to $\mathbf{u}_2$. The operator ab maps $\mathrm{im}\,a$ into itself; an eigenvalue λ of that restriction — this is the one place algebraic closure is spent — makes $aba - \lambda a$ a member of A of strictly smaller rank, hence zero, and then $a\mathbf{u}_2 = \lambda\, a\mathbf{u}_1$ contradicts independence. ③ One rank-one operator $\mathbf{v}_0\varphi_0$ in A gives all of them: multiplying on the left moves $\mathbf{v}_0$ anywhere, and multiplying on the

right moves φ_0 anywhere. ④ Rank-one operators span $\mathrm{End}(V)$.

Proof. Write $\mathbf{v}\varphi$ for the operator $\mathbf{x} \mapsto \varphi(\mathbf{x})\mathbf{v}$, where $\mathbf{v} \in V$ and $\varphi \in V^*$; it has rank 1 exactly when $\mathbf{v} \neq \mathbf{0}$ and $\varphi \neq 0$, and every operator of rank at most 1 has this form, since an operator with image $\mathrm{span}(\mathbf{v})$, $\mathbf{v} \neq \mathbf{0}$, sends each $\mathbf{x}$ to a unique multiple $\varphi(\mathbf{x})\mathbf{v}$, and φ so defined is linear.

Step 1: a member of least rank. Since $\mathrm{id}_V \in A$ and $\dim V \geq 1$, the set $\{a \in A : a \neq 0\}$ is non-empty. Let

$$r = \min\{\operatorname{rank} a : a \in A,\ a \neq 0\} \geq 1,$$

and fix $a \in A$ with $a \neq 0$ and $\operatorname{rank} a = r$.

Step 2: $r = 1$. Suppose $r \geq 2$. Then $\dim \operatorname{im} a \geq 2$, so there are $\mathbf{u}_1, \mathbf{u}_2 \in V$ with $a\mathbf{u}_1$ and $a\mathbf{u}_2$ independent; in particular $a\mathbf{u}_1 \neq \mathbf{0}$. By Lemma 22.5.1 there is $b \in A$ with $b(a\mathbf{u}_1) = \mathbf{u}_2$.

Put $W = \operatorname{im} a$, a subspace of dimension r. Then $ab(W) \subseteq \operatorname{im} a = W$, so $s := (ab)|_W$ is an operator on W. Its characteristic polynomial p_s is monic of degree $r \geq 1$, hence non-constant, hence has a root $\lambda \in F$ because F is algebraically closed; by Theorem 8.2.1, λ is an eigenvalue of s, so $\ker(s - \lambda\,\mathrm{id}_W) \neq \{\mathbf{0}\}$.

Consider $c := aba - \lambda a$, which lies in A because A is closed under products and linear combinations. For every $\mathbf{x} \in V$,

$$c\,\mathbf{x} = (ab - \lambda\,\mathrm{id}_V)(a\mathbf{x}) = (s - \lambda\,\mathrm{id}_W)(a\mathbf{x}),$$

the second equality because $a\mathbf{x} \in W$. Hence $\operatorname{im} c = (s - \lambda\,\mathrm{id}_W)(W)$, and Theorem 3.3.1 applied to $s - \lambda\,\mathrm{id}_W$ on W gives

$$\operatorname{rank} c = r - \dim \ker(s - \lambda\,\mathrm{id}_W) \leq r - 1.$$

By the minimality of r, an element of A of rank less than r must be 0, so $c = 0$, that is, $aba = \lambda a$. Applying both sides to $\mathbf{u}_1$ and using $ba\mathbf{u}_1 = \mathbf{u}_2$,

$$a\mathbf{u}_2 = (aba)\mathbf{u}_1 = \lambda\, a\mathbf{u}_1,$$

which contradicts the independence of $a\mathbf{u}_1$ and $a\mathbf{u}_2$. Therefore $r = 1$.

Step 3: A contains every operator of rank at most one. By Step 2 there is $a_0 \in A$ with $\operatorname{rank} a_0 = 1$; write $a_0 = \mathbf{v}_0\varphi_0$ with $\mathbf{v}_0 \neq \mathbf{0}$ and $\varphi_0 \neq 0$.

Left multiplication. For $b \in A$ and $\mathbf{x} \in V$ we get $b\,a_0\,\mathbf{x} = \varphi_0(\mathbf{x})\,b\mathbf{v}_0$, that is, $ba_0 = (b\mathbf{v}_0)\varphi_0$. By Lemma 22.5.1, $A\mathbf{v}_0 = V$, so

$$\mathbf{v}\varphi_0 \in A \qquad \text{for every } \mathbf{v} \in V.$$

Right multiplication. For $c \in A$ we get $a_0c = \mathbf{v}_0(\varphi_0 \circ c)$. Put

$$S = \{\, \varphi_0 \circ c : c \in A \,\} \subseteq V^*,$$

the image of the linear map $A \to V^*$, $c \mapsto \varphi_0 \circ c$, and hence a subspace of V^*.

Claim. $S = V^*$.

Proof. Let $U = \{\mathbf{x} \in V : \varphi(\mathbf{x}) = 0 \text{ for every } \varphi \in S\}$, a subspace of V. It is A-invariant: if $\mathbf{x} \in U$ and $d \in A$, then for every $c \in A$ we have $cd \in A$ and so $\varphi_0(c(d\mathbf{x})) = \varphi_0((cd)\mathbf{x}) = 0$, whence $d\mathbf{x} \in U$. It is not all of V: taking $c = \mathrm{id}_V$ shows $\varphi_0 \in S$, and $\varphi_0 \neq 0$ gives some $\mathbf{x}$ with $\varphi_0(\mathbf{x}) \neq 0$. Irreducibility therefore forces $U = \{\mathbf{0}\}$.

Let $d = \dim S$ and pick a basis $\varphi_1, \dots, \varphi_d$ of S. The linear map $\Theta\colon V \to F^d$, $\Theta(\mathbf{x}) = (\varphi_1(\mathbf{x}), \dots, \varphi_d(\mathbf{x}))$, has kernel exactly $U = \{\mathbf{0}\}$, since a vector killed by a basis of S is killed by all of S. So Θ is injective and Theorem 3.3.1 gives $\dim V \leq d$. On the other hand S is a subspace of V^*, and $\dim V^* = \dim V$ by Corollary 4.1.4, so $d \leq \dim V$. Hence $d = \dim V^*$ and $S = V^*$ by Theorem 1.6.8.

■

Now let $\mathbf{v} \in V$ and $\varphi \in V^*$ be arbitrary. Choose $c \in A$ with $\varphi = \varphi_0 \circ c$, which the Claim allows, and $b \in A$ with $b\mathbf{v}_0 = \mathbf{v}$, which Lemma 22.5.1 allows when $\mathbf{v} \neq \mathbf{0}$ (and for $\mathbf{v} = \mathbf{0}$ take $b = 0$). Then for every $\mathbf{x}$,

$$(b\,a_0\,c)\mathbf{x} = b\big(\varphi_0(c\mathbf{x})\,\mathbf{v}_0\big) = \varphi(\mathbf{x})\,\mathbf{v},$$

so $\mathbf{v}\varphi = ba_0c \in A$.

Step 4: rank-one operators span. Let $t \in \mathrm{End}(V)$, let $(\mathbf{v}_1, \dots, \mathbf{v}_n)$ be a basis of V and $(\varphi_1, \dots, \varphi_n)$ its dual basis (Definition 4.1.3). The operator $\sum_{i=1}^{n} (t\mathbf{v}_i)\varphi_i$ sends $\mathbf{v}_j$ to $t\mathbf{v}_j$ for each j, because $\varphi_i(\mathbf{v}_j) = \delta_{ij}$; two operators agreeing on a basis are equal, so $t = \sum_i (t\mathbf{v}_i)\varphi_i$. Each summand lies in A by Step 3, and A is a subspace, so $t \in A$. This proves $A = \mathrm{End}(V)$.

■

The theorem is stronger than it may look. It says that irreducibility, a statement about *subspaces*, forces a statement about *dimension*: over an algebraically closed field, an irreducibly acting subalgebra of $\mathrm{End}(V)$ has dimension exactly $(\dim V)^2$, the largest possible. There is no room between "acts irreducibly" and "is everything".

The version about sets rather than algebras is worth recording alongside it, since a group of invertible operators is a set closed under composition and not a subspace.

Corollary 22.5.3 — An Irreducible Multiplicative Set Spans the Whole Algebra

Let F be algebraically closed, V a vector space over F with $1 \leq \dim V < \infty$, and let $\mathcal{S} \subseteq \mathrm{End}(V)$ be a set with $\mathrm{id}_V \in \mathcal{S}$ that is closed under composition. If the only subspaces $U \subseteq V$ with $s(U) \subseteq U$ for all $s \in \mathcal{S}$ are $\{\mathbf{0}\}$ and V, then $\mathrm{span}(\mathcal{S}) = \mathrm{End}(V)$.

Proof. Put $A = \mathrm{span}(\mathcal{S})$. It is a subspace containing id_V, and it is closed under multiplication: a product of two linear combinations of members of $\mathcal{S}$ expands, by bilinearity of composition, into a linear combination of products of members of $\mathcal{S}$, which lie in $\mathcal{S}$. So A is a subalgebra. A subspace U is A-invariant if and only if it is invariant under every member of $\mathcal{S}$, since invariance is preserved by linear combinations. So V is irreducible as an A-space, and Theorem 22.5.2 gives $A = \mathrm{End}(V)$.

■

Warning. **Burnside is false over a field that is not algebraically closed.** Let $F = \mathbb{R}$, $V = \mathbb{R}^2$ and

$$A = \left\{ \begin{pmatrix} x & -y \\ y & x \end{pmatrix} : x, y \in \mathbb{R} \right\},$$

the span of $\mathbf{I}_2$ and $\mathbf{Q} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. Since $\mathbf{Q}^2 = -\mathbf{I}_2$, this is a subalgebra, and it acts irreducibly: an invariant line would be spanned by a real eigenvector of $\mathbf{Q}$, and $p_{\mathbf{Q}} = x^2 + 1$ has no real root. Yet $\dim A = 2$, not 4, so $A \neq M_2(\mathbb{R})$. This is the same witness §04 used against the second half of Schur's lemma (Theorem 22.4.1), and the reason is the same: an operator on a real space need have no eigenvalue, and Step 2 of the proof needs one.

Quick check. Let $A \subseteq M_2(\mathbb{C})$ be the subalgebra generated by $\mathbf{X} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $\mathbf{Z} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. Without computing products, what must $\dim A$ be, and why?

Solution. It must be 4, so $A = M_2(\mathbb{C})$. A one-dimensional invariant subspace would be a common eigenvector of $\mathbf{X}$ and $\mathbf{Z}$. The eigenvectors of $\mathbf{Z}$ are the multiples of $\mathbf{e}_1$ and of $\mathbf{e}_2$, and $\mathbf{X}\mathbf{e}_1 = \mathbf{e}_2$ is not a multiple of $\mathbf{e}_1$, nor is $\mathbf{X}\mathbf{e}_2 = \mathbf{e}_1$ a multiple of $\mathbf{e}_2$. So A acts irreducibly on $\mathbb{C}^2$, and Theorem 22.5.2 gives $A = M_2(\mathbb{C})$. Directly: $\mathbf{I}_2, \mathbf{X}, \mathbf{Z}$ and $\mathbf{X}\mathbf{Z} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ are independent, which confirms it.

22.5.4 The double commutant theorem

Burnside handles the irreducible case. The general case is not "A is everything" — a diagonal algebra is not everything — but a statement about how faithfully A is recorded by its commutant. The right hypothesis is semisimplicity of the action, and it cannot be weakened to nothing, as the warning below shows.

The engine is a single step: an operator in A'' can be matched by a member of A on **one** given vector.

Lemma 22.5.4 — Matching on One Vector

Let W be a finite-dimensional vector space over F and let $B \subseteq \mathrm{End}(W)$ be a subalgebra with $\mathrm{id}_W \in B$ which acts **semisimply** on W: every B-invariant subspace of W has a B-invariant complement (Definition 22.3.4). Then for every $t \in B''$ and every $\mathbf{w} \in W$ there is $b \in B$ with $b\mathbf{w} = t\mathbf{w}$.

Idea. The subspace $B\mathbf{w}$ is invariant, so it has an invariant complement, and the projection p onto $B\mathbf{w}$ along that complement commutes with B. Being in B'', the operator t commutes with p, hence cannot move $\mathbf{w}$ out of the image of p, which is $B\mathbf{w}$.

Proof. Put $U = B\mathbf{w} = \{b\mathbf{w} : b \in B\}$, a subspace of W (the image of $b \mapsto b\mathbf{w}$) which is B-invariant, since $b_1(b\mathbf{w}) = (b_1 b)\mathbf{w}$ for $b_1 \in B$. By hypothesis there is a B-invariant subspace U_1 with $W = U \oplus U_1$. Let $p \in \mathrm{End}(W)$ be the projection onto U along U_1 (Theorem 3.10.1 (b)).

$p \in B'$. Indeed, let $b \in B$ and write $\mathbf{x} = \mathbf{u} + \mathbf{u}_1$ with $\mathbf{u} \in U$, $\mathbf{u}_1 \in U_1$. Then $b\mathbf{u} \in U$ and $b\mathbf{u}_1 \in U_1$ by invariance, so $b\mathbf{x} = b\mathbf{u} + b\mathbf{u}_1$ is the decomposition of $b\mathbf{x}$, giving $p(b\mathbf{x}) = b\mathbf{u} = b(p\mathbf{x})$.

Since $t \in B''$ and $p \in B'$, we have $tp = pt$. Also $\mathbf{w} = \mathrm{id}_W \mathbf{w} \in B\mathbf{w} = U$, so $p\mathbf{w} = \mathbf{w}$. Therefore

$$t\mathbf{w} = t(p\mathbf{w}) = p(t\mathbf{w}) \in \operatorname{im} p = U = B\mathbf{w},$$

so $t\mathbf{w} = b\mathbf{w}$ for some $b \in B$.

■

Matching on one vector is not yet matching everywhere. The trick that upgrades it is to run the lemma not on V but on n copies of V at once, where one cleverly chosen vector carries a whole basis.

Theorem 22.5.5 — Double Commutant Theorem

Let F be **any** field, let V be a finite-dimensional vector space over F, and let $A \subseteq \mathrm{End}(V)$ be a subalgebra with $\mathrm{id}_V \in A$. Assume that A acts **semisimply** on V: every A-invariant subspace of V has an A-invariant complement (Definition 22.3.4). Then

$$A'' = A.$$

Idea. **Step roadmap.** ① Lemma 22.5.4 matches $t \in A''$ with some $a \in A$ on one vector. ② To match on a whole basis at once, let A act diagonally on $V^n = V \oplus \cdots \oplus V$ ($n = \dim V$) and apply the lemma there to the single vector whose n entries are the basis vectors. ③ For that we must check two things about the copied algebra $\tilde{A}$: that it still acts semisimply, which Theorem 22.3.3 supplies, and that $\tilde{t}$ lies in $\tilde{A}''$, which is a computation with the $n \times n$ array of components of an operator on V^n.

Proof. The inclusion $A \subseteq A''$ was noted above, so only $A'' \subseteq A$ needs proof. Let $t \in A''$, let $n = \dim V$; if $n = 0$ there is nothing to prove, so let $n \geq 1$.

Step 1: the copied algebra. Let $V^n = V \oplus \cdots \oplus V$ be the product of n copies of V (Definition 3.9.1), and for $s \in \mathrm{End}(V)$ let $\tilde{s} \in \mathrm{End}(V^n)$ be given by $\tilde{s}(\mathbf{x}_1, \ldots, \mathbf{x}_n) = (s\mathbf{x}_1, \ldots, s\mathbf{x}_n)$. The map $s \mapsto \tilde{s}$ is linear and satisfies $\widetilde{s_1 s_2} = \tilde{s}_1 \tilde{s}_2$ and $\widetilde{\mathrm{id}_V} = \mathrm{id}_{V^n}$, so $\tilde{A} = \{\tilde{a} : a \in A\}$ is a subalgebra of $\mathrm{End}(V^n)$ containing the identity.

Step 2: $\tilde{A}$ acts semisimply on V^n. Since A acts semisimply on V, Theorem 22.3.3 writes $V = W_1 + \cdots + W_q$ with each W_j an irreducible A-invariant subspace. For $1 \leq k \leq n$ let $\iota_k \colon V \to V^n$ place a vector in the k-th slot and $\mathbf{0}$ elsewhere; it is injective and satisfies $\iota_k(s\mathbf{x}) = \tilde{s}\,\iota_k(\mathbf{x})$. Hence $\iota_k(W_j)$ is $\tilde{A}$-invariant, and it is irreducible, because ι_k carries the A-invariant subspaces of W_j bijectively onto the $\tilde{A}$-invariant subspaces of

$\iota_k(W_j)$. Every element of V^n is the sum of its n slots, so

$$V^n = \sum_{k=1}^{n} \sum_{j=1}^{q} \iota_k(W_j),$$

a sum of irreducible $\tilde{A}$-invariant subspaces. By the converse half of Theorem 22.3.3, $\tilde{A}$ acts semisimply on V^n.

Step 3: $\tilde{t} \in \tilde{A}''$. Let $\pi_k \colon V^n \to V$ be the k-th coordinate map. Every $s \in \mathrm{End}(V^n)$ is determined by its components $s_{kl} = \pi_k \circ s \circ \iota_l \in \mathrm{End}(V)$, through $\pi_k(s\mathbf{x}) = \sum_l s_{kl}\mathbf{x}_l$. Comparing components in $s\tilde{a} = \tilde{a}s$ gives

$$(s\tilde{a})_{kl} = s_{kl}\, a, \qquad (\tilde{a}s)_{kl} = a\, s_{kl},$$

so $s \in \tilde{A}'$ if and only if every s_{kl} lies in A'. Now let $s \in \tilde{A}'$. Then $(\tilde{t}s)_{kl} = t\, s_{kl}$ and $(s\tilde{t})_{kl} = s_{kl}\, t$, and these agree because $s_{kl} \in A'$ and $t \in A''$. Hence $\tilde{t}$ commutes with every $s \in \tilde{A}'$, that is, $\tilde{t} \in \tilde{A}''$.

Step 4: conclude. Let $(\mathbf{v}_1, \dots, \mathbf{v}_n)$ be a basis of V and put $\tilde{\mathbf{v}} = (\mathbf{v}_1, \dots, \mathbf{v}_n) \in V^n$. By Steps 1–3 the hypotheses of Lemma 22.5.4 hold for $B = \tilde{A}$ on $W = V^n$, with $\tilde{t} \in \tilde{A}''$. So there is $a \in A$ with $\tilde{a}\,\tilde{\mathbf{v}} = \tilde{t}\,\tilde{\mathbf{v}}$, that is, $a\mathbf{v}_i = t\mathbf{v}_i$ for every i. Two operators agreeing on a basis are equal, so $t = a \in A$. This proves $A'' \subseteq A$, and with the reverse inclusion, $A'' = A$.

■

Notice which hypotheses were used where. Algebraic closure was **not** used: the double commutant theorem holds over every field, unlike Burnside. Finite dimension was used for the basis in Step 4 and inside Theorem 22.3.3. Semisimplicity was used exactly once, to produce the invariant complement in Lemma 22.5.4.

Warning. **Neither hypothesis can simply be dropped.**

Without the identity. Take $A = \{0\} \subseteq \mathrm{End}(F^2)$, a subspace closed under composition but with no identity element of $\mathrm{End}(F^2)$ in it. Every subspace of F^2 is A-invariant and every subspace has a complement, so the condition on invariant complements holds; but $A' = M_2(F)$ and $A'' = \{\lambda \mathbf{I}_2\}$ by Proposition 22.1.5, so $A'' \neq A$.

Without semisimplicity. Let $A \subseteq M_2(F)$ be the upper triangular matrices. The line $\mathrm{span}(\mathbf{e}_1)$ is A-invariant, and it is the **only** invariant line: if $\mathbf{v} = (v_1, v_2)$ has $v_2 \neq 0$, then $\mathbf{E}_{12}\mathbf{v} = v_2\mathbf{e}_1$ is a non-zero multiple of $\mathbf{e}_1$ and does not lie in $\mathrm{span}(\mathbf{v})$. A complement of $\mathrm{span}(\mathbf{e}_1)$ would be an invariant line other than $\mathrm{span}(\mathbf{e}_1)$, so there is none and A does not act semisimply. Here $A' = \{\lambda \mathbf{I}_2\}$: a matrix commuting with $\mathbf{E}_{11}$ and $\mathbf{E}_{22}$ is diagonal, and commuting with $\mathbf{E}_{12}$ then forces the two diagonal entries to agree. Hence $A'' = \{\lambda \mathbf{I}_2\}' = M_2(F)$, which is strictly larger than A.

Remark. Semisimplicity is sufficient but not necessary. Let $\mathbf{N} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $A = \{x\mathbf{I}_2 + y\mathbf{N}\}$. Solving $\mathbf{XN} = \mathbf{NX}$ gives exactly the matrices $x\mathbf{I}_2 + y\mathbf{N}$, so $A' = A$ and therefore $A'' = A$ — even though A does not act semisimply, the invariant line $\mathrm{span}(\mathbf{e}_1) = \ker \mathbf{N}$ again being the only one.

Remark. The name has two sources. In finite dimensions the result above is due to Wedderburn, and the argument through n copies of V is the finite-dimensional shadow of Jacobson's density theorem, which we do not prove. For algebras of operators on a Hilbert space there is an analytic statement of the same shape, von Neumann's double commutant theorem, which is outside this book.

22.5.5 The commutant of one operator, revisited

The two earlier computations of the book now read as computations of A' for the smallest interesting algebra: the one generated by a single operator.

Corollary 22.5.6 — The Commutant of a Single Operator

Let V be a finite-dimensional vector space over F, let $T \in \mathcal{L}(V)$, and let $A = F[T] \subseteq \mathrm{End}(V)$ be the algebra of all polynomials in T. Then

$$A' = \{S \in \mathcal{L}(V) : ST = TS\}.$$

Consequently the following two earlier results are computations of A'.

(a) If $F = \mathbb{C}$ and the matrix of T in some basis is $\mathbf{A}_1 \oplus \cdots \oplus \mathbf{A}_r$ with the $\mathbf{A}_p$ of pairwise disjoint spectra, then in that same basis every member of A' has a block **diagonal** matrix for the partition into those block sizes (Corollary 11.10.4).

(b) If the matrix of T in some basis is a basic Weyr matrix of Weyr structure $(w_1, \ldots, w_s)$, then in that same basis every member of A' has a block **upper triangular** matrix for the partition $w_1 + \cdots + w_s$ (Proposition 9.4.6).

If moreover T is diagonalizable with distinct eigenvalues $\lambda_1, \ldots, \lambda_k$ and $d_i = \dim E_{\lambda_i}(T)$, then A acts semisimply, $\dim A = k$, $\dim A' = \sum_{i=1}^{k} d_i^2$, and $A'' = A$.

Idea. Nothing in (a) and (b) is new: whatever commutes with T commutes with every polynomial in it, so the two earlier computations were computations of A' all along. The diagonalizable case is where the second commutant enters. The Lagrange polynomials evaluated at T are the projections onto the eigenspaces, and they turn out to be a basis of A; a commuting operator is exactly one that preserves each eigenspace and is otherwise unconstrained, which counts A'; and the same projections assemble an invariant complement for any invariant subspace, which is the hypothesis Theorem 22.5.5 needs.

Proof. An operator commutes with every polynomial in T as soon as it commutes with T, and $T \in A$; this gives the displayed description of A'. Parts (a) and (b) are then the cited results verbatim, read for the matrix of T in the given basis.

For the last sentence, let T be diagonalizable, $E_i = E_{\lambda_i}(T)$, so $V = E_1 \oplus \cdots \oplus E_k$ by Theorem 8.4.1 (c). Let $\ell_i \in F[x]$ be the Lagrange polynomial with $\ell_i(\lambda_j) = \delta_{ij}$ (Theorem 5.6.1) and $P_i = \ell_i(T)$. Evaluating on each E_j, where T acts as λ_j, shows P_i is the projection onto E_i along the other summands. Since $T^m = \sum_i \lambda_i^m P_i$ for every $m \geq 0$, the algebra A is spanned by $P_1, \ldots, P_k$, which are independent because $P_i P_j = \delta_{ij} P_i$ and each $P_i \neq 0$: applying $\sum_i c_i P_i = 0$ to a non-zero vector of E_j gives $c_j = 0$. So $\dim A = k$.

By Theorem 8.9.1, every $S \in A'$ maps each E_i into itself; conversely such an S commutes with T, because both ST and TS act as $\lambda_i S$ on E_i. So A' is the set of operators preserving all the E_i, and restricting gives a linear bijection $A' \to \mathrm{End}(E_1) \times \cdots \times \mathrm{End}(E_k)$; hence $\dim A' = \sum_i d_i^2$. Each P_i preserves every E_j, so $P_i \in A'$.

Finally, A acts semisimply. Let U be an A-invariant subspace. Then U is T-invariant, and $T|_U$ is diagonalizable (Corollary 8.8.3), so U has a basis of eigenvectors of T (Theorem 8.4.1, (a) $\Leftrightarrow$ (b)) and therefore $U = (U \cap E_1) \oplus \cdots \oplus (U \cap E_k)$. Choose a complement C_i of $U \cap E_i$ inside E_i for each i (Theorem 1.7.6) and put $C = C_1 \oplus \cdots \oplus C_k$. Then $V = U \oplus C$, and C is A-invariant because $P_j(C) = C_j \subseteq C$ and the P_j span A. So Theorem 22.5.5 applies and gives $A'' = A$.

■

So the diagonalizable case is an instance of Theorem 22.5.5, reached here by hand; the Weyr case in (b) is **not**, since $F[\mathbf{W}]$ does not act semisimply once $s \geq 2$. That is the honest shape of the relationship: the two earlier sections computed first commutants in cases where the second commutant theorem has nothing to say, and this section explains what extra hypothesis would make the computation reversible.

Example. (The Two Extremes)

Inside $M_n(F)$ with $n \geq 2$, compute A' and A'' for (i) A the diagonal matrices, and (ii) A the scalar matrices.

Solution.

(i) Let $A = \{\mathrm{diag}(c_1, \ldots, c_n)\}$. Then $\mathbf{X}$ commutes with $\mathbf{E}_{ii}$ for every i exactly when $\mathbf{X}$ is diagonal, since $(\mathbf{X}\mathbf{E}_{ii})_{kl} = x_{ki}\delta_{il}$ and $(\mathbf{E}_{ii}\mathbf{X})_{kl} = \delta_{ik}x_{il}$, and comparing at (k, i) with $k \neq i$ gives $x_{ki} = 0$. So $A' = A$, and applying the prime again, $A'' = A' = A$. This agrees with Theorem 22.5.5: the diagonal algebra acts semisimply, F^n being the direct sum of the n coordinate lines, each of which is invariant and one-dimensional, hence irreducible.

(ii) Let $A = \{\lambda \mathbf{I}_n\}$. Every matrix commutes with a scalar matrix, so $A' = M_n(F)$, and $A'' = M_n(F)' = \{\lambda \mathbf{I}_n\} = A$ by Proposition 22.1.5. Again $A'' = A$, as it must be: the scalars act semisimply because every subspace is invariant and every subspace has a complement.

The two examples sit at opposite ends. In (i) the commutant is as small as the algebra; in (ii) the commutant is everything. In both, applying the prime a second time returns to the start, which is what the theorem promises whenever the action is semisimple.

22.5.6 Exercises

22.5.6.1 A. Check your understanding

Exercise A1.

(a) State Burnside's theorem, with every hypothesis.

(b) Give the field hypothesis of Theorem 22.5.5, and say why it differs from the one in (a).

(c) True or false, with a reason: if $A \subseteq \mathrm{End}(V)$ is a subalgebra containing id_V, then $A''' = A'$.

(d) Explain in one sentence why $\{\mathbf{0}\}$ and V being the only A-invariant subspaces does **not** by itself imply $A\mathbf{v} = V$ for $\mathbf{v} \neq \mathbf{0}$.

Solution.

(a) F algebraically closed, V finite-dimensional over F with $\dim V \geq 1$, $A \subseteq \mathrm{End}(V)$ a subalgebra containing id_V, and V irreducible as an A-space; the conclusion is $A = \mathrm{End}(V)$.

(b) Theorem 22.5.5 has no field hypothesis at all: it holds over every field. Algebraic closure entered Burnside only to produce an eigenvalue of $(ab)|_{\mathrm{im}\,a}$, and the double commutant proof never needs an eigenvalue — it needs an invariant complement, which semisimplicity hands over directly.

(c) True, and it holds for any subset: it is Proposition 22.1.4 (d). The two ingredients are (c) of that proposition, $\mathcal{S} \subseteq \mathcal{S}''$, and (b), that $\mathcal{S} \subseteq \mathcal{T}$ implies $\mathcal{T}' \subseteq \mathcal{S}'$. Applying the prime to $A \subseteq A''$ gives $A''' \subseteq A'$, and applying the inclusion $B \subseteq B''$ to $B = A'$ gives $A' \subseteq A'''$.

(d) Because $A\mathbf{v}$ could be $\{\mathbf{0}\}$ if A contained no operator sending $\mathbf{v}$ anywhere non-zero; the identity in A is what rules this out, as in the warning after Lemma 22.5.1.

22.5.6.2 B. Practice

Exercise B1: Determine which are irreducible.

For each subalgebra of $M_2(\mathbb{C})$, determine whether it acts irreducibly on $\mathbb{C}^2$, and hence whether it equals $M_2(\mathbb{C})$. Justify your answer.

(a) The algebra generated by $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$.

(b) The algebra generated by $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $\begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix}$.

(c) The algebra of all matrices $\begin{pmatrix} a & b \\ 0 & a \end{pmatrix}$.

Solution.

(a) Not irreducible. With $\mathbf{N} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ we have $\mathbf{N}^2 = \mathbf{0}$, so the algebra is $\{x\mathbf{I}_2 + y\mathbf{N}\}$, and $\mathrm{span}(\mathbf{e}_1) = \mathrm{im}\,\mathbf{N}$ is invariant, proper and non-zero. It is not $M_2(\mathbb{C})$; its dimension is 2.

(b) Irreducible, so it equals $M_2(\mathbb{C})$ by Theorem 22.5.2. The eigenvectors of $\mathrm{diag}(1, i)$ are the multiples of $\mathbf{e}_1$ and of $\mathbf{e}_2$ (the diagonal entries are distinct), and the swap matrix maps each of those lines to the other, so no line is invariant under both.

(c) Not irreducible: this is the algebra of (a), written out. The invariant line is again $\mathrm{span}(\mathbf{e}_1)$.

Exercise B2: A commutant and a double commutant.

Let $\mathbf{A} = \operatorname{diag}(1, 1, 2) \in M_3(\mathbb{R})$ and let $A = \mathbb{R}[\mathbf{A}] \subseteq M_3(\mathbb{R})$.

(a) Compute $\dim A$.

(b) Describe A' explicitly and compute $\dim A'$.

(c) Compute A'', and check the answer against Theorem 22.5.5.

Solution.

(a) The eigenvalues are 1 and 2, each with a non-zero eigenspace, so $m_{\mathbf{A}} = (x-1)(x-2)$ and, by the count in Corollary 22.5.6 with $k = 2$, $\dim A = 2$: a basis is $\mathbf{I}_3, \mathbf{A}$, equivalently $\mathbf{P}_1 = \operatorname{diag}(1, 1, 0)$, $\mathbf{P}_2 = \operatorname{diag}(0, 0, 1)$.

(b) $E_1 = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ and $E_2 = \operatorname{span}(\mathbf{e}_3)$. Every matrix in A' preserves both (Theorem 8.9.1), and conversely a matrix preserving both commutes with $\mathbf{A}$, since $\mathbf{A}$ acts as a scalar on each; so a matrix lies in A' exactly when it has the shape

$$\begin{pmatrix} p & q & 0 \\ u & v & 0 \\ 0 & 0 & w \end{pmatrix}.$$

Its dimension is $2^2 + 1^2 = 5$.

(c) A matrix commuting with all of these must commute in particular with $\operatorname{diag}(1, 1, 0)$ and $\operatorname{diag}(0, 0, 1)$, hence be of the same block shape, and its 2×2 block must commute with all of $M_2(\mathbb{R})$, hence be scalar (Proposition 22.1.5). So $A'' = \{\alpha\mathbf{P}_1 + \beta\mathbf{P}_2\} = A$, of dimension 2. Since $\mathbf{A}$ is diagonalizable, A acts semisimply, and Theorem 22.5.5 predicts exactly $A'' = A$.

Exercise B3: One theorem, once.

Let F be algebraically closed, let V be finite-dimensional over F with $\dim V \geq 2$, and let $A \subseteq \operatorname{End}(V)$ be a **commutative** subalgebra containing id_V. Prove that A does not act irreducibly on V.

Solution. Suppose it did. By Theorem 22.5.2, $A = \operatorname{End}(V)$. But $\operatorname{End}(V)$ is not commutative when $\dim V \geq 2$: choosing a basis and the operators with matrices $\mathbf{E}_{12}$ and $\mathbf{E}_{21}$ gives $\mathbf{E}_{12}\mathbf{E}_{21} = \mathbf{E}_{11} \neq \mathbf{E}_{22} = \mathbf{E}_{21}\mathbf{E}_{12}$. This contradicts commutativity of A, so A is not irreducible.

22.5.6.3 C. Going deeper

Exercise C1: The rank-one step needs its hypothesis.

In Step 2 of the proof of Theorem 22.5.2, the operator ab was restricted to $W = \operatorname{im} a$ and an eigenvalue was extracted.

(a) Prove that $ab(W) \subseteq W$, and give an example of $a, b \in M_2(F)$ with $ba(\operatorname{im} a) \not\subseteq \operatorname{im} a$, so that the order of the product matters.

(b) Take $F = \mathbb{R}$, $A = \{x\mathbf{I}_2 + y\mathbf{Q}\}$ with $\mathbf{Q} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. Compute the minimal rank r of a non-zero member of A and confirm that the conclusion $r = 1$ fails.

(c) Which sentence of Step 2 fails for this A? Say exactly where the hypothesis on F was used.

Solution.

(a) $ab(W) = a(b(W)) \subseteq \operatorname{im} a = W$, since a is applied last. For the other order take $a = \mathbf{E}_{11}$ and $b = \mathbf{E}_{21}$ in $M_2(F)$. Then $\operatorname{im} a = \operatorname{span}(\mathbf{e}_1)$ and $ba\,\mathbf{e}_1 = \mathbf{E}_{21}\mathbf{e}_1 = \mathbf{e}_2 \notin \operatorname{span}(\mathbf{e}_1)$.

(b) A non-zero $x\mathbf{I}_2 + y\mathbf{Q}$ has determinant $x^2 + y^2 > 0$ for real x, y not both zero, so it is invertible and has rank 2. Hence $r = 2$, and the conclusion $r = 1$ fails; consistently, A contains no rank-one matrix and is not all of $M_2(\mathbb{R})$.

(c) The sentence "its characteristic polynomial has a root $\lambda \in F$ because F is algebraically closed". With $a = \mathbf{I}_2$ and $b = \mathbf{Q}$ we get $W = \mathbb{R}^2$ and $s = \mathbf{Q}$, whose characteristic polynomial $x^2 + 1$ has no real root. Everything before that sentence is valid over any field.

Exercise C2: Commutants under a change of basis.

Let V be finite-dimensional over F, let $A \subseteq \operatorname{End}(V)$ be a subalgebra containing id_V, and let $g \in \operatorname{End}(V)$ be invertible. Put $gAg^{-1} = \{gag^{-1} : a \in A\}$.

(a) Prove that gAg^{-1} is a subalgebra containing id_V and that $(gAg^{-1})' = gA'g^{-1}$.

(b) Deduce that if $A'' = A$ then $(gAg^{-1})'' = gAg^{-1}$.

(c) Hence show that the conclusion of Theorem 22.5.5 is a property of the algebra up to similarity, and use this to give, for each $n \geq 2$, a subalgebra of $M_n(F)$ with $A'' \neq A$.

Solution.

(a) The map $a \mapsto gag^{-1}$ is linear, sends id_V to id_V, and satisfies $(ga_1g^{-1})(ga_2g^{-1}) = g(a_1a_2)g^{-1}$, so the image is a subalgebra containing the identity. For the commutant: t commutes with every gag^{-1} if and only if $g^{-1}tg$ commutes with every a, that is, if and only if $g^{-1}tg \in A'$, that is, $t \in gA'g^{-1}$.

(b) Apply (a) twice: $(gAg^{-1})'' = (gA'g^{-1})' = gA''g^{-1} = gAg^{-1}$.

(c) By (b), whether $A'' = A$ holds is unchanged by replacing A with a similar copy, so it is a property of the similarity class. For a failure in $M_n(F)$ take $A_n =$ all upper triangular matrices. The same computation as in the warning after Theorem 22.5.5, done with the matrix units $\mathbf{E}_{ii}$ and $\mathbf{E}_{i,i+1}$, gives $A_n' = \{\lambda\mathbf{I}_n\}$, hence $A_n'' = M_n(F) \neq A_n$; and by (b) every similar copy gA_ng^{-1} fails too.

Exercise C3: Is this look-alike a theorem?.

Let V be finite-dimensional over an algebraically closed F and let $A \subseteq \operatorname{End}(V)$ be a subalgebra with $\mathrm{id}_V \in A$.

(a) Prove: if V is irreducible as an A-space then $A' = \{\lambda\,\mathrm{id}_V\}$.

(b) Is the converse true? That is, does $A' = \{\lambda\, \mathrm{id}_V\}$ force V to be irreducible? Justify your answer.

Hint for (b): consider the upper triangular matrices in $M_2(F)$.

Solution.

(a) By Theorem 22.5.2, $A = \mathrm{End}(V)$, so $A' = \mathrm{End}(V)' = \{\lambda\, \mathrm{id}_V\}$ by Proposition 22.1.5. (This recovers the second half of Schur's lemma, Theorem 22.4.1, in this special case.)

(b) No. Let A be the upper triangular matrices in $M_2(F)$. The warning after Theorem 22.5.5 computes $A' = \{\lambda \mathbf{I}_2\}$, yet $\mathrm{span}(\mathbf{e}_1)$ is a proper non-zero invariant subspace, so F^2 is not irreducible as an A-space — and indeed $A \neq M_2(F)$. A trivial commutant is therefore strictly weaker than irreducibility; it is semisimplicity, not a small commutant, that makes the commutant remember the algebra.

22.6 The Structure Theorem

§05 settled the extreme case: over an algebraically closed field, an algebra of operators with no invariant subspace to hide in is the whole of $\mathrm{End}(V)$. Most algebras are not like that. This section shows that, over an algebraically closed field and under one hypothesis — semisimplicity — that extreme case is nevertheless the only building block there is. Every such algebra is a product of full matrix algebras, and the sizes of the blocks are determined by the algebra. That is the structure theorem, and it is the last piece of general theory the chapter needs: from here on the work is to apply it to groups.

Throughout, F is a field and A is an associative algebra with identity, finite-dimensional over F and with $A \neq \{0\}$.

22.6.1 Products of matrix algebras

Before proving that something is a product of matrix algebras, we should say what the product is and look at a few.

A product of algebras is a list of algebras run side by side, with nothing passing between the slots.

Definition 22.6.1 — Product of algebras

Let $A_1, \dots, A_k$ be F-algebras. Their **product** $A_1 \times \cdots \times A_k$ is the product vector space (Definition 3.9.1) with multiplication defined **slot by slot**,

$$(x_1, \dots, x_k)(y_1, \dots, y_k) = (x_1 y_1, \dots, x_k y_k),$$

and identity $(1_{A_1}, \dots, 1_{A_k})$.

The axioms of Definition 13.12.1 hold slot by slot because they hold in each A_i, and $\dim(A_1 \times \cdots \times A_k) = \sum_i \dim A_i$ by Theorem 3.9.1. Two features of a product will be used constantly.

First, the element e_i with 1_{A_i} in slot i and 0 elsewhere satisfies $e_i^2 = e_i$, $e_i e_j = 0$ for $i \neq j$, and $e_1 + \cdots + e_k = 1$. Second, the product is almost never commutative, but its center always contains the k-dimensional span of $e_1, \ldots, e_k$.

Example. (Three products, seen from two sides)

Identify each of the following with a product of matrix algebras over F, and give its dimension: (i) the diagonal matrices in $M_n(F)$; (ii) $M_n(F)$ itself; (iii) the block diagonal matrices in $M_5(F)$ with blocks of sizes $2, 2, 1$, where the **two** 2×2 blocks are allowed to differ.

Solution.

(i) The map $\mathrm{diag}(c_1, \ldots, c_n) \mapsto (c_1, \ldots, c_n)$ is a bijection, is linear, sends $\mathbf{I}_n$ to $(1, \ldots, 1)$, and is multiplicative because diagonal matrices multiply entry by entry. So the diagonal matrices form $F \times \cdots \times F = M_1(F)^n$, of dimension $n = \sum_{i=1}^{n} 1^2$.

(ii) $M_n(F)$ is the product with one slot, $k = 1$ and $n_1 = n$, of dimension n^2.

(iii) Writing a block diagonal matrix as the list of its blocks gives $M_2(F) \times M_2(F) \times M_1(F)$, since block diagonal matrices multiply blockwise (Theorem 7.1.4, applied twice). Its dimension is $4 + 4 + 1 = 9 = 2^2 + 2^2 + 1^2$.

In all three the dimension is $\sum_i n_i^2$. The theorem below says that this is not a coincidence of the examples.

22.6.2 The regular representation

An abstract algebra has no vectors to act on until we give it some, and the cheapest supply is the algebra itself.

Remark. The vocabulary is §03's and §04's. An **A-space** is a vector space V with an algebra homomorphism $A \to \mathrm{End}(V)$, written $a\mathbf{v}$ (Definition 22.3.2); **invariant** subspace and **irreducible** A-space are as in Definition 22.3.3; and a **homomorphism of A-spaces** $f\colon V \to W$ is what §04 calls an A-map, a linear map with $f(a\mathbf{v}) = af(\mathbf{v})$ (Definition 22.4.1). A bijective one is an **isomorphism**, and we then write $V \cong W$.

The **regular representation** of A, introduced in §03 (Definition 22.3.2), is A acting on itself by left multiplication: $L\colon A \to \mathrm{End}(A)$, $L_a(x) = ax$. It is injective because $L_a(1_A) = a$; this is exactly Theorem 22.1.3. Its invariant subspaces are the subspaces $I \subseteq A$ with $AI \subseteq I$, which is to say the **left ideals** of §02. So the irreducible invariant subspaces of the regular representation are the **minimal left ideals**: the non-zero left ideals containing no smaller non-zero left ideal.

We call A **semisimple** when the regular representation is semisimple in the sense of §03 (Definition 22.3.4): every left ideal of A has a complementary left ideal.

22.6.3 The structure theorem

Theorem 22.6.1 — Wedderburn's Structure Theorem, Algebraically Closed Case

Let F be an **algebraically closed** field and let $A \neq \{0\}$ be a **semisimple** finite-dimensional F-algebra: every left ideal of A has a complementary left ideal. Then there are an integer $k \geq 1$, integers $n_1, \ldots, n_k \geq 1$ and an isomorphism of F-algebras

$$A \;\cong\; M_{n_1}(F) \times \cdots \times M_{n_k}(F).$$

Moreover k and the multiset $\{n_1, \ldots, n_k\}$ depend only on A: they are the number of isomorphism classes of irreducible A-spaces and their dimensions.

Idea. **Step roadmap.** ① Break the regular representation into minimal left ideals. ② Keep one from each isomorphism class, say $V_1, \ldots, V_k$, and map A into $\mathrm{End}(V_1) \times \cdots \times \mathrm{End}(V_k)$ by letting it act on each. ③ The map is injective because an element acting as zero on every V_i acts as zero on all of A, hence kills 1. ④ It is surjective: on $W = V_1 \oplus \cdots \oplus V_k$, Schur's lemma computes the commutant of the image to be the scalars-on-each-slot, and Theorem 22.5.5 turns that into the statement that the image is everything preserving the slots. ⑤ Uniqueness: read the n_i off as the dimensions of the irreducible A-spaces, which no choice in the proof can change.

Proof. **Step 1: split the regular representation.** Regard A as an A-space by left multiplication. Its invariant subspaces are the left ideals, and by hypothesis every one of them has an invariant complement. By Theorem 22.3.3, (a) ⇒ (c), A is a **direct** sum of finitely many irreducible invariant subspaces:

$$A = L_1 \oplus \cdots \oplus L_m, \qquad L_j \text{ a minimal left ideal.}$$

Since $A \neq \{0\}$ we have $m \geq 1$.

Step 2: one representative per class. Being isomorphic is an equivalence relation on the list $L_1, \ldots, L_m$; pick one member from each class and call the chosen spaces $V_1, \ldots, V_k$. They are pairwise non-isomorphic, and every L_j is isomorphic to exactly one of them. Put $n_i = \dim V_i \geq 1$ and let $\rho_i \colon A \to \mathrm{End}(V_i)$ be the homomorphism giving the action. Then $k \geq 1$.

Step 3: the map, and its injectivity. Let

$$\Phi \colon A \to \mathrm{End}(V_1) \times \cdots \times \mathrm{End}(V_k), \qquad \Phi(a) = (\rho_1(a), \ldots, \rho_k(a)).$$

Each ρ_i is an algebra homomorphism and the product has slot-by-slot operations (Definition 22.6.1), so Φ is an algebra homomorphism, and $\Phi(1_A)$ is the identity.

Suppose $\Phi(a) = 0$. Fix j, let i be the index with $L_j \cong V_i$, and let $f \colon L_j \to V_i$ be an isomorphism of A-spaces. For $x \in L_j$ we get $f(ax) = \rho_i(a) f(x) = 0$, and f is injective, so $ax = 0$. Thus $aL_j = \{0\}$ for every j, and since $A = L_1 + \cdots + L_m$ we get $aA = \{0\}$. In particular $a = a1_A = 0$. So Φ is injective.

Step 4: surjectivity. Let $W = V_1 \oplus \cdots \oplus V_k$ be the product space, with A acting slot by slot, and let $B \subseteq \mathrm{End}(W)$ be the image of A under this action; B is a subalgebra containing id_W. Let $D \subseteq \mathrm{End}(W)$ be the set of operators mapping each V_i into itself. Restricting to the slots identifies D with $\mathrm{End}(V_1) \times \cdots \times \mathrm{End}(V_k)$ as an algebra, and under that identification $\Phi(A)$ corresponds to B. So it suffices to prove $B = D$.

B acts semisimply on W. Each V_i is B-invariant, and a subspace of V_i is B-invariant exactly when it is A-invariant, so each V_i is an irreducible B-invariant subspace; and $W = V_1 + \cdots + V_k$. By Theorem 22.3.3, B acts semisimply.

The commutant of B. Let $\iota_j \colon V_j \to W$ and $\pi_i \colon W \to V_i$ be the slot inclusions and projections, and for $s \in \mathrm{End}(W)$ put $s_{ij} = \pi_i \circ s \circ \iota_j \colon V_j \to V_i$. Then s commutes with the action of every $a \in A$ if and only if

$$s_{ij}\,\rho_j(a) = \rho_i(a)\,s_{ij} \qquad \text{for all } i, j, a,$$

that is, if and only if every s_{ij} is a homomorphism of A-spaces. For $i \neq j$ the spaces V_i and V_j are irreducible and non-isomorphic, so Theorem 22.4.1 gives $s_{ij} = 0$. For $i = j$ the field is algebraically closed and V_i is irreducible, so the second part of Theorem 22.4.1 gives $s_{ii} = \lambda_i \,\mathrm{id}_{V_i}$ for some $\lambda_i \in F$. Conversely every operator of that shape commutes with B. Hence

$$B' = \{\, \lambda_1 \,\mathrm{id}_{V_1} \oplus \cdots \oplus \lambda_k \,\mathrm{id}_{V_k} : \lambda_i \in F \,\}.$$

The double commutant of B. Let $p_i \in \mathrm{End}(W)$ be the projection onto V_i along the other slots; it is the member of B' with $\lambda_i = 1$ and the other $\lambda_j = 0$. If $t \in B''$, then t commutes with p_i, so

$$t(V_i) = t(\operatorname{im} p_i) = \operatorname{im}(tp_i) = \operatorname{im}(p_i t) \subseteq \operatorname{im} p_i = V_i,$$

which says $t \in D$. Conversely every $t \in D$ commutes with each $\lambda_1 \,\mathrm{id} \oplus \cdots \oplus \lambda_k \,\mathrm{id}$, so $D \subseteq B''$. Hence $B'' = D$.

Conclusion. B is a subalgebra of $\mathrm{End}(W)$ containing id_W and acting semisimply, so Theorem 22.5.5 gives $B = B'' = D$. Therefore Φ is surjective, and with Step 3 it is an isomorphism of algebras onto $\mathrm{End}(V_1) \times \cdots \times \mathrm{End}(V_k)$.

Step 5: matrices. Choosing a basis $\mathcal{B}_i$ of V_i makes $T \mapsto [T]_{\mathcal{B}_i}$ a linear bijection $\mathrm{End}(V_i) \to M_{n_i}(F)$ (Theorem 3.6.4) which is multiplicative (Theorem 3.6.2) and sends id_{V_i} to $\mathbf{I}_{n_i}$, hence an isomorphism of algebras. Doing this in each slot gives

$$A \cong M_{n_1}(F) \times \cdots \times M_{n_k}(F).$$

Step 6: uniqueness. We first identify all irreducible A-spaces.

> *Claim.* If $A = \sum_j L_j$ with each L_j an irreducible left ideal, then every irreducible A-space is isomorphic to some L_j.

> *Proof.* Let U be an irreducible A-space and pick $\mathbf{u} \in U$, $\mathbf{u} \neq \mathbf{0}$. The map $f \colon A \to U$, $f(a) = a\mathbf{u}$, is a homomorphism of A-spaces from the regular representation, since $f(ba) = (ba)\mathbf{u} = b f(a)$. Its image is an invariant subspace containing $f(1_A) = \mathbf{u} \neq \mathbf{0}$, hence equals U by irreducibility. From $A = \sum_j L_j$ we get $U = \sum_j f(L_j)$, so $f(L_{j_0}) \neq \{\mathbf{0}\}$ for some j_0. Then $f|_{L_{j_0}} \colon L_{j_0} \to U$ is a non-zero homomorphism between irreducible A-spaces, hence an isomorphism by Theorem 22.4.1.

■

Now let $B_0 = M_{p_1}(F) \times \cdots \times M_{p_l}(F)$ be any product of matrix algebras, and let $C_j = F^{p_j}$ carry the action of B_0 through the j-th slot. Each C_j is irreducible: given $\mathbf{v} \neq \mathbf{0}$ in F^{p_j} and any $\mathbf{w}$, extend $\mathbf{v}$ to a basis (Theorem 1.6.5) and let $\mathbf{X}$ be the matrix sending $\mathbf{v} \mapsto \mathbf{w}$ and the other basis vectors to $\mathbf{0}$; then $M_{p_j}(F)\mathbf{v} = F^{p_j}$, so no proper non-zero invariant subspace exists. They are pairwise non-isomorphic: the idempotent $e_j \in B_0$ acts as the identity on C_j and as 0 on C_i for $i \neq j$, so an isomorphism $f : C_j \to C_i$ would give $f(\mathbf{v}) = f(e_j\mathbf{v}) = e_j f(\mathbf{v}) = \mathbf{0}$ for every $\mathbf{v}$, forcing $f = 0$. Finally, for each j and each column index c let $C_{j,c} \subseteq B_0$ consist of the elements whose slots other than j are $\mathbf{0}$ and whose j-th slot has all columns but the c-th equal to $\mathbf{0}$. Each $C_{j,c}$ is a left ideal, the map $x \mapsto x_j\mathbf{e}_c$ is an isomorphism of B_0-spaces $C_{j,c} \to C_j$, and B_0 is the direct sum of the $C_{j,c}$. So by the Claim the irreducible B_0-spaces are, up to isomorphism, exactly $C_1, \ldots, C_l$: there are l of them and their dimensions are $p_1, \ldots, p_l$.

An isomorphism of algebras $A \to B_0$ turns B_0-spaces into A-spaces, preserving irreducibility and isomorphism. So if $A \cong M_{n_1}(F) \times \cdots \times M_{n_k}(F)$, then A has exactly k isomorphism classes of irreducible spaces and their dimensions are $n_1, \ldots, n_k$. Both quantities are determined by the isomorphism class of A alone, so they do not depend on the choices made in Steps 1 and 2. This proves the theorem.

■

Remark. The case $k = 1$ says that a semisimple algebra with only one irreducible space, up to isomorphism, is a full matrix algebra. Burnside's theorem (Theorem 22.5.2) is the concrete counterpart of that sentence: there the algebra arrives already written as operators on an irreducible space, its hypothesis is irreducibility rather than semisimplicity, and its conclusion is the sharper equality $A = \mathrm{End}(V)$ in place of an isomorphism. The proof above does not use Theorem 22.5.2; what it borrows from §05 is the double commutant theorem.

Two hypotheses carried the proof, and it is worth saying again where. **Semisimplicity** was used twice: to split the regular representation in Step 1, and to apply the double commutant theorem in Step 4. **Algebraic closure** was used once, in the second half of Schur's lemma, to know that a homomorphism of an irreducible space to itself is a scalar. Drop algebraic closure and the diagonal slots become division algebras rather than F; that is the general theorem, quoted below and not proved.

Corollary 22.6.2 — Counting Dimensions in the Wedderburn Form

In the situation of Theorem 22.6.1,

$$\dim_F A = n_1^2 + \cdots + n_k^2,$$

and the center $Z(A) = \{z \in A : za = az \text{ for all } a \in A\}$ has $\dim_F Z(A) = k$.

Proof. The dimension of a product is the sum of the dimensions (Theorem 3.9.1) and $\dim M_{n_i}(F) = n_i^2$, which gives the first formula. An isomorphism of algebras carries the center onto the center, so we may compute in $M_{n_1}(F) \times \cdots \times M_{n_k}(F)$. Multiplication is slot by slot, so $(z_1, \ldots, z_k)$ is central exactly when each z_i is central in $M_{n_i}(F)$, and by Proposition 22.1.5, read through the identification of $M_{n_i}(F)$ with $\mathrm{End}(F^{n_i})$, that means $z_i = \lambda_i \mathbf{I}_{n_i}$. So $Z(A)$ is isomorphic to F^k as a vector space, of dimension k.

■

The two numbers in the corollary are the whole invariant content of a semisimple algebra over an algebraically closed field: k is read from the center, and then the n_i are k positive integers with $\sum n_i^2 = \dim A$. When A is the group algebra $\mathbb{C}[G]$ of a finite group, whose dimension is $|G|$ by Definition 22.1.5, this becomes the sum-of-squares formula $|G| = \sum_i n_i^2$ for the dimensions of the irreducible representations, and k turns out to be the number of conjugacy classes. Both statements are proved later in this chapter, once Maschke's theorem supplies the missing hypothesis that $\mathbb{C}[G]$ is semisimple.

Quick check. A semisimple algebra A over $\mathbb{C}$ has $\dim A = 10$ and $\dim Z(A) = 4$. What are the possible block sizes?

Solution. By Corollary 22.6.2 we need $k = 4$ positive integers with $n_1^2 + \cdots + n_4^2 = 10$. No n_i can be 3 or more: that block alone contributes at least 9, and the other three contribute at least 3, for a total of at least 12. So every n_i is 1 or 2; if t of them equal 2, the sum is $4t + (4 - t) = 10$, so $t = 2$. Up to order the block sizes are $1, 1, 2, 2$ and $A \cong \mathbb{C} \times \mathbb{C} \times M_2(\mathbb{C}) \times M_2(\mathbb{C})$.

22.6.4 What is quoted and not proved

The theorem above is the case this book can carry. The general statement is older and stronger, and we record it honestly.

Remark. **The Wedderburn–Artin theorem.** Over an arbitrary field F, a finite-dimensional semisimple F-algebra is isomorphic to a product

$$M_{n_1}(D_1) \times \cdots \times M_{n_k}(D_k),$$

where each D_i is a **division algebra** over F in the sense of §04 — an F-algebra, here finite-dimensional and not assumed commutative, in which every non-zero element has a multiplicative inverse. The result is due to Wedderburn, and Artin extended it beyond finite dimension. **We do not prove it.** The reason is not that the argument is long — it follows the same route, with Schur's lemma supplying $\mathrm{End}_A(V_i) = D_i$ in place of F — but that this book has never built the theory of division rings. The only non-commutative division algebra it has met is the quaternions $\mathbb{H}$ over $\mathbb{R}$ (Definition 13.12.3), and one example is not a theory. Nothing in this chapter depends on the general statement.

Remark. **Wedderburn's little theorem.** Every **finite** division ring is commutative, hence a field. This is a separate theorem of Wedderburn's, and we do not prove it either; the standard proofs use counting arguments in group theory or cyclotomic polynomials, neither of which this book has developed. Its effect on the theorem above is that over a finite field the division algebras D_i are all fields, so the blocks are matrix algebras over field extensions of F.

Warning. **Semisimplicity is not automatic, so the theorem does not apply to every algebra.** The upper triangular matrices in $M_2(F)$ form a three-dimensional algebra which is **not** a product of matrix algebras: a product $M_{n_1}(F) \times \cdots \times M_{n_k}(F)$ of total dimension 3 would need $\sum n_i^2 = 3$, hence $k = 3$ and all $n_i = 1$, hence a commutative algebra; but $\mathbf{E}_{11}\mathbf{E}_{12} = \mathbf{E}_{12}$ while $\mathbf{E}_{12}\mathbf{E}_{11} = \mathbf{0}$. What fails is semisimplicity: as §05

noted, $\operatorname{span}(\mathbf{e}_1)$ is an invariant subspace with no invariant complement. §03 identifies the obstruction as the radical of the algebra (Definition 22.3.5).

22.6.5 Two worked decompositions

Example. (The group algebra of a cyclic group of order four)

Let $C_4 = \{1, g, g^2, g^3\}$ be a cyclic group of order 4, so $g^4 = 1$; it exists, for instance as the subgroup $\{1, i, -1, -i\}$ of $(\mathbb{C} \setminus \{0\}, \cdot)$ with $g = i$ (Theorem 0.10.2). Find the Wedderburn form of the group algebra $\mathbb{C}[C_4]$ (Definition 22.1.5) explicitly, and exhibit the idempotents $e_1, \dots, e_4$ of the product.

Solution. Let $\omega_1 = 1$, $\omega_2 = i$, $\omega_3 = -1$, $\omega_4 = -i$ be the four complex numbers with $\omega^4 = 1$. Define

$$\Phi\colon \mathbb{C}[C_4] \to \mathbb{C}^4, \qquad \Phi\Big(\sum_{t=0}^{3} a_t g^t\Big) = \Big(\sum_{t} a_t \omega_r^t\Big)_{r=1}^{4}.$$

It is linear by construction. It is multiplicative: it is enough to check on the basis g^s, g^t, where $g^s g^t = g^{s+t}$ with the exponent read modulo 4, and $\omega_r^{s+t} = \omega_r^s \omega_r^t$ with $\omega_r^4 = 1$ making the reduction harmless. It sends $1 = g^0$ to $(1,1,1,1)$. Its matrix in the basis $(1, g, g^2, g^3)$ of the source and the standard basis of $\mathbb{C}^4$ is

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & i & -1 & -i \\ 1 & -1 & 1 & -1 \\ 1 & -i & -1 & i \end{pmatrix},$$

whose determinant is $-16i \neq 0$, so Φ is bijective. Hence

$$\mathbb{C}[C_4] \cong \mathbb{C} \times \mathbb{C} \times \mathbb{C} \times \mathbb{C} = M_1(\mathbb{C})^{\,4},$$

with $k = 4$ and $n_1 = n_2 = n_3 = n_4 = 1$; the dimension count $\sum n_i^2 = 4 = |C_4|$ checks out, and $Z(\mathbb{C}[C_4])$ is everything, of dimension 4, as it must be for a commutative algebra.

The idempotents pull back to

$$e_r = \tfrac{1}{4} \sum_{t=0}^{3} \overline{\omega_r^t}\, g^t, \qquad r = 1, \dots, 4,$$

explicitly

$$e_1 = \tfrac{1}{4}(1 + g + g^2 + g^3), \quad e_2 = \tfrac{1}{4}(1 - ig - g^2 + ig^3),$$
$$e_3 = \tfrac{1}{4}(1 - g + g^2 - g^3), \quad e_4 = \tfrac{1}{4}(1 + ig - g^2 - ig^3).$$

A direct expansion confirms $e_r^2 = e_r$, $e_r e_s = 0$ for $r \neq s$, and $e_1 + e_2 + e_3 + e_4 = 1$. For instance

$$\begin{aligned} 16\, e_2^2 &= (1 - ig - g^2 + ig^3)^2 \\ &= 4 - 4ig - 4g^2 + 4ig^3 = 16\, e_2, \end{aligned}$$

where the middle equality collects the sixteen products $(\pm 1, \pm i) g^{s+t}$ with $g^4 = 1$.

The matrix in that example is, up to the factor $\frac{1}{2}$ that normalizes its columns, the Fourier matrix of size four (Example (The Fourier matrix of size four), Theorem 11.9.3). That is not a coincidence, and a later section of this chapter explains it: the characters of a finite abelian group assemble into a Fourier matrix, and the isomorphism above is the discrete Fourier transform.

Example. (An algebra already in Wedderburn form)

What is the Wedderburn form of $M_2(\mathbb{C})$, and what are its irreducible spaces?

Solution. It is $M_2(\mathbb{C})$ itself: $k = 1$ and $n_1 = 2$, with $\dim = 4 = 2^2$ and $\dim Z = 1$, the scalars (Proposition 22.1.5). To see that the theorem applies, note that $M_2(\mathbb{C}) = C_1 \oplus C_2$ where C_c is the set of matrices whose only non-zero column is the c-th; each C_c is a left ideal isomorphic to $\mathbb{C}^2$ as an $M_2(\mathbb{C})$-space, and $\mathbb{C}^2$ is irreducible, so Theorem 22.3.3 makes the algebra semisimple. There is exactly one isomorphism class of irreducible space, namely $\mathbb{C}^2$, of dimension 2 — which is Step 6's description of k and n_1. Note that $M_2(\mathbb{C})$ is **not** a product of two smaller algebras: it is simple (Theorem 22.2.2), while a product with $k \geq 2$ has the proper non-zero two-sided ideal $e_1 A$.

22.6.6 Exercises

22.6.6.1 A. Check your understanding

Exercise A1.

(a) State Theorem 22.6.1 with all of its hypotheses, and say which hypothesis fails for the upper triangular matrices in $M_2(\mathbb{C})$.

(b) Where in the proof is algebraic closure used, and what replaces the conclusion when it is dropped?

(c) A semisimple algebra over $\mathbb{C}$ has dimension 5. List all possibilities for its Wedderburn form.

(d) True or false, with a reason: a commutative semisimple algebra over $\mathbb{C}$ of dimension n is isomorphic to $\mathbb{C}^n$.

Solution.

(a) F algebraically closed, $A \neq \{0\}$ finite-dimensional over F, and A semisimple, that is, every left ideal has a complementary left ideal. For the upper triangular matrices semisimplicity fails: $\operatorname{span}(\mathbf{e}_1)$ is an invariant subspace of the natural action with no invariant complement, and correspondingly the left ideal of matrices with second row zero has no complementary left ideal.

(b) In Step 4, in the second half of Theorem 22.4.1, to know that s_{ii} is a scalar. Without algebraic closure the slots become $M_{n_i}(D_i)$ for division algebras D_i, which is the Wedderburn–Artin theorem quoted above and not proved here.

(c) We need positive integers with $\sum n_i^2 = 5$: either $1 + 4$, giving $\mathbb{C} \times M_2(\mathbb{C})$, or $1 + 1 + 1 + 1 + 1$, giving $\mathbb{C}^5$.

(d) True. By Theorem 22.6.1, $A \cong \prod_i M_{n_i}(\mathbb{C})$, and $M_{n_i}(\mathbb{C})$ is commutative only for $n_i = 1$ (otherwise $\mathbf{E}_{11}\mathbf{E}_{12} \neq \mathbf{E}_{12}\mathbf{E}_{11}$). So every $n_i = 1$ and $k = \sum n_i^2 = n$.

22.6.6.2 B. Practice

Exercise B1: Determine which are semisimple.

Determine which of the following algebras over $\mathbb{C}$ are semisimple, and give the Wedderburn form of those that are. Justify your answer.

(a) The diagonal matrices in $M_3(\mathbb{C})$.
(b) $\mathbb{C}[x]/(x^2)$.
(c) $\mathbb{C}[x]/(x^2-1)$.

Solution.

(a) Semisimple, and equal to $\mathbb{C}\times\mathbb{C}\times\mathbb{C}$ by Example (Three products, seen from two sides) (i). As a check on semisimplicity: the algebra is the direct sum of the three left ideals $\mathbb{C}\mathbf{E}_{ii}$, each of dimension 1 and hence irreducible, so Theorem 22.3.3 applies.

(b) Not semisimple. Both algebras here are quotients of the infinite-dimensional algebra $\mathbb{C}[x]$ by the ideal generated by one polynomial (Definition 5.2.1, Definition 22.2.2), and each has dimension 2, a basis being the classes of 1 and x. Write ε for the class of x in $\mathbb{C}[x]/(x^2)$, so the algebra is $\{a+b\varepsilon\}$ with $\varepsilon^2=0$. The line $\mathbb{C}\varepsilon$ is a left ideal, and it is the **only** one-dimensional one: a left ideal spanned by $a+b\varepsilon$ with $a\neq 0$ contains $\varepsilon(a+b\varepsilon)=a\varepsilon$, hence ε, hence is at least two-dimensional. So $\mathbb{C}\varepsilon$ has no complementary left ideal, which would have to be one-dimensional. Consistently, a product of matrix algebras of dimension 2 would be $\mathbb{C}\times\mathbb{C}$, which has no non-zero element squaring to 0.

(c) Semisimple, with Wedderburn form $\mathbb{C}\times\mathbb{C}$. The map $p+(x^2-1)\mapsto(p(1),p(-1))$ is linear, multiplicative and unital, and on the representatives $a+bx$ it reads $(a+b,a-b)$, which vanishes only for $a=b=0$; an injective linear map between spaces of dimension 2 is bijective (Theorem 3.3.1). A product of copies of $\mathbb{C}$ is semisimple by the argument in (a).

Exercise B2: A dimension count.

Let A be a semisimple algebra over $\mathbb{C}$ with $\dim A=8$ and $\dim Z(A)=5$. Determine the Wedderburn form of A, and the dimensions of the irreducible A-spaces.

Solution. By Corollary 22.6.2, $k=\dim Z(A)=5$ and $n_1^2+\cdots+n_5^2=8$ with every $n_i\geq 1$. Writing $8=5+3$, we need $\sum(n_i^2-1)=3$, and n^2-1 takes the values $0,3,8,\ldots$ for $n=1,2,3,\ldots$. So exactly one n_i equals 2 and the rest equal 1. Hence

$$A\cong\mathbb{C}\times\mathbb{C}\times\mathbb{C}\times\mathbb{C}\times M_2(\mathbb{C}),$$

and the irreducible A-spaces have dimensions $1,1,1,1,2$.

Exercise B3: The group algebra of a group of order three.

Let $C_3=\{1,g,g^2\}$ with $g^3=1$. Imitating Example (The group algebra of a cyclic group of order four), produce an explicit algebra isomorphism $\mathbb{C}[C_3]\to\mathbb{C}^3$ and write

down the three idempotents.

Solution. Let $\omega = e^{2\pi i/3}$, so $1, \omega, \omega^2$ are the cube roots of 1 and $1 + \omega + \omega^2 = 0$. Define

$$\Phi\Big(\sum_{t=0}^{2} a_t g^t\Big) = \Big(\sum_t a_t,\ \sum_t a_t \omega^t,\ \sum_t a_t \omega^{2t}\Big).$$

As in the example, Φ is linear, multiplicative (because $\omega^{s+t} = \omega^s \omega^t$ and $\omega^3 = 1$) and unital. Its matrix has rows $(1,1,1)$, $(1,\omega,\omega^2)$, $(1,\omega^2,\omega)$; it is a Vandermonde matrix in the distinct nodes $1, \omega, \omega^2$, hence invertible. So $\mathbb{C}[C_3] \cong \mathbb{C}^3$, and $\sum n_i^2 = 3 = |C_3|$. The idempotents are

$$e_1 = \tfrac{1}{3}(1 + g + g^2),$$
$$e_2 = \tfrac{1}{3}(1 + \omega^2 g + \omega g^2),$$
$$e_3 = \tfrac{1}{3}(1 + \omega g + \omega^2 g^2),$$

the r-th being $\frac{1}{3}\sum_t \overline{\omega^{(r-1)t}} g^t$.

22.6.6.3 C. Going deeper

Exercise C1: Simple plus semisimple.

Let F be algebraically closed and let $A \neq \{0\}$ be a finite-dimensional semisimple F-algebra.

(a) Prove that A is simple (has no two-sided ideal but $\{0\}$ and A) if and only if $k = 1$, that is, $A \cong M_n(F)$ for some n.

(b) Deduce that a finite-dimensional simple semisimple algebra over $\mathbb{C}$ has square dimension.

Hint for (a): in a product, the set of elements whose slots after the first are zero is a two-sided ideal.

Solution.

(a) ($\Leftarrow$) If $k = 1$ then $A \cong M_n(F)$, which is simple by Theorem 22.2.2, and simplicity is preserved by an algebra isomorphism.
($\Rightarrow$) Suppose $k \geq 2$ and write $A \cong M_{n_1}(F) \times \cdots \times M_{n_k}(F)$. The set I of elements whose slots $2, \ldots, k$ are 0 is closed under addition and under multiplication by any element on either side, because multiplication is slot by slot; so I is a two-sided ideal. It is non-zero, since $e_1 \in I$, and it is not all of A, since $e_2 \notin I$. So A is not simple. Contrapositively, simple forces $k = 1$.

(b) By (a), $A \cong M_n(F)$, so $\dim A = n^2$ by Corollary 22.6.2 with $k = 1$.

Exercise C2: How often each irreducible appears.

Keep the notation of Theorem 22.6.1 and of its proof, so that $A = L_1 \oplus \cdots \oplus L_m$ with each L_j isomorphic to exactly one V_i. Let m_i be the number of indices j with $L_j \cong V_i$. For A-spaces V, W write $\mathrm{Hom}_A(V, W)$ for the vector space of homomorphisms of A-spaces $V \to W$.

(a) Prove that $f \mapsto f(1_A)$ is a linear bijection $\mathrm{Hom}_A(A, V) \to V$ for every A-space V, where A carries the regular representation.

(b) Prove that $\dim \mathrm{Hom}_A(L_j, V_i)$ is 1 if $L_j \cong V_i$ and 0 otherwise.

(c) Deduce that $m_i = n_i$: each irreducible appears in the regular representation exactly as many times as its dimension. Check the result against Corollary 22.6.2.

Hint for (b): Theorem 22.4.1, both parts.

Solution.

(a) The map is linear. It is injective: if $f(1_A) = \mathbf{0}$ then $f(a) = f(a1_A) = af(1_A) = \mathbf{0}$ for every a. It is surjective: given $\mathbf{v} \in V$, the map $a \mapsto a\mathbf{v}$ is linear and satisfies $(ba)\mathbf{v} = b(a\mathbf{v})$, so it is a homomorphism of A-spaces sending 1_A to $\mathbf{v}$.

(b) If $L_j \ncong V_i$, the first part of Theorem 22.4.1 says every homomorphism between these irreducible spaces is 0, so the dimension is 0. If $L_j \cong V_i$, fix an isomorphism h; then $f \mapsto h^{-1}f$ is a linear bijection $\mathrm{Hom}_A(L_j, V_i) \to \mathrm{Hom}_A(L_j, L_j)$, and by the second part of Theorem 22.4.1, valid because F is algebraically closed, every self-homomorphism of the irreducible space L_j is a scalar. So the dimension is 1.

(c) A homomorphism out of a direct sum is the list of its restrictions to the summands, so $\mathrm{Hom}_A(A, V_i)$ is linearly isomorphic to $\bigoplus_j \mathrm{Hom}_A(L_j, V_i)$, of dimension m_i by (b). By (a) that dimension is $\dim V_i = n_i$. Hence $m_i = n_i$. As a check, $\dim A = \sum_j \dim L_j = \sum_i m_i n_i = \sum_i n_i^2$, which is Corollary 22.6.2.

Exercise C3: Change the field.

Let $A = \{x\mathbf{I}_2 + y\mathbf{Q} : x, y \in \mathbb{R}\} \subseteq M_2(\mathbb{R})$, where $\mathbf{Q} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$.

(a) Prove that A is a semisimple $\mathbb{R}$-algebra of dimension 2.

(b) Show that A is **not** isomorphic to a product $M_{n_1}(\mathbb{R}) \times \cdots \times M_{n_k}(\mathbb{R})$, and identify which hypothesis of Theorem 22.6.1 fails.

(c) Prove that A is itself a division algebra over $\mathbb{R}$ and identify it.

Solution.

(a) $\mathbf{Q}^2 = -\mathbf{I}_2$, so A is closed under multiplication and is a subalgebra containing $\mathbf{I}_2$, of dimension 2. Every non-zero element $x\mathbf{I}_2 + y\mathbf{Q}$ has determinant $x^2 + y^2 > 0$, hence is invertible in $M_2(\mathbb{R})$, and its inverse $(x^2 + y^2)^{-1}(x\mathbf{I}_2 - y\mathbf{Q})$ lies in A. So every non-zero left ideal contains an invertible element and hence equals A; the only left ideals are $\{0\}$ and A, and each has a complementary left ideal (the other one). So A is semisimple.

(b) A product with $\sum n_i^2 = 2$ must be $\mathbb{R} \times \mathbb{R}$, which contains the non-zero element $(1, 0)$ with $(1, 0)(0, 1) = (0, 0)$; but in A the product of two non-zero elements is non-zero, since both are invertible. So no such isomorphism exists. The hypothesis that fails is algebraic closure: $\mathbb{R}$ is not algebraically closed.

(c) By (a) every non-zero element of A is invertible, and its inverse again lies in A, so A is a division algebra over $\mathbb{R}$; it is a copy of $\mathbb{C}$, the map $x\mathbf{I}_2 + y\mathbf{Q} \mapsto x + yi$

being a bijective algebra homomorphism. This is the D_1 that would appear in the quoted Wedderburn–Artin form of A.

22.7 Group Representations

Sections 01–06 studied an algebra of operators in the abstract. A group is not an algebra — its elements cannot be added — but a group can be made to *act* by operators, and then the operators it produces span an algebra. This section sets up that translation: a representation of a group G over F is the same thing as a representation of the group algebra $F[G]$, so everything proved about algebras applies at once. The section's main theorem, Maschke's, says when the resulting algebra is semisimple, and its hypothesis on the field is not decoration: we exhibit a group and a field where the conclusion fails outright.

Throughout, G is a **finite** group, written multiplicatively, with its identity element written 1, and F is a field. All vector spaces are finite-dimensional over F. Where a statement needs F to be $\mathbb{C}$, or needs a condition on $\operatorname{char} F$, the statement says so.

22.7.1 Letting a group act by operators

The book's groups so far have been groups *of* matrices or *of* permutations: $\mathrm{GL}_n(F)$ (Example (Groups)), the symmetric group S_n, the classical groups of Chapter 13. Such a group arrives with its linear algebra attached. An abstract group does not. If all we know about G is its multiplication table, the only way to bring linear algebra to bear is to manufacture operators out of it.

The manufacture has one requirement. Group multiplication must become composition of operators, since composition is the only product on $\mathcal{L}(V)$, and every group element must become an **invertible** operator, since every group element can be undone. That is exactly the definition of a homomorphism into the group $\mathrm{GL}(V)$ of invertible operators on V, a group under composition by the same argument that makes $\mathrm{GL}_n(F)$ one (Example (Groups)).

A representation is a way of realizing the elements of a group as invertible operators, so that multiplying in the group means composing the operators.

Definition 22.7.1 — Representation of a group

Let G be a group, F a field and V a finite-dimensional vector space over F. A **representation** of G on V over F is a group homomorphism

$$\rho\colon G \to \mathrm{GL}(V),$$

that is, a map assigning to each $g \in G$ an invertible operator $\rho(g)$ on V such that $\rho(gh) = \rho(g)\rho(h)$ **for all** $g, h \in G$. The space V is the **representation space**, and $\dim V$ is the **degree** of ρ. The representation is **faithful** if ρ is injective. When $V = F^n$ we speak of a **matrix representation** and write $\rho(g) \in \mathrm{GL}_n(F)$.

In words: to give a representation is to attach to each $g \in G$ an invertible operator $\rho(g)$ on one fixed space V, in such a way that the operator attached to a product is the composition of

the operators attached to the factors. Two conditions that look like extra demands are already implied by Theorem 0.10.3: $\rho(1) = \mathrm{id}_V$, and $\rho(g^{-1}) = \rho(g)^{-1}$ for every g. So we never have to check them.

Note what is **not** required. Nothing says ρ is injective, and nothing says the operators $\rho(g)$ are distinct. The constant map $g \mapsto \mathrm{id}_V$ is a perfectly good representation; it simply carries no information about G.

Examples. Fix a finite group G and a field F.

- **The trivial representation.** $V = F$ and $\rho(g) = \mathrm{id}_F$ for every g. It is a representation because $\mathrm{id}_F \cdot \mathrm{id}_F = \mathrm{id}_F$, matching $\rho(gh) = \rho(g)\rho(h)$. Its degree is 1. This is the degenerate case, and it is not a curiosity: it is one of the basic building blocks, and in Section 08 it is the piece that detects averages.
- **The sign representation of S_n.** $V = F$ and $\rho(\sigma) = \mathrm{sgn}(\sigma)\,\mathrm{id}_F$, where sgn is the sign of a permutation (Definition 6.3.2). It is a homomorphism because $\mathrm{sgn}(\sigma\tau) = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\tau)$ (Theorem 6.3.1). Over a field of characteristic 2 we have $-1 = 1$, so the sign representation coincides with the trivial one; over $\mathbb{C}$ it does not. It is faithful on S_2, whose two elements have signs 1 and -1, but not on S_n for $n \geq 3$, where $\mathrm{sgn}((1\ 2\ 3)) = 1 = \mathrm{sgn}(\mathrm{id})$ while $(1\ 2\ 3) \neq \mathrm{id}$.
- **The permutation representation of S_n.** $V = F^n$ and $\rho(\sigma)\mathbf{e}_i = \mathbf{e}_{\sigma(i)}$, extended linearly (Theorem 3.1.6). Then $\rho(\sigma)\rho(\tau)\mathbf{e}_i = \rho(\sigma)\mathbf{e}_{\tau(i)} = \mathbf{e}_{\sigma(\tau(i))} = \rho(\sigma\tau)\mathbf{e}_i$, where the last step uses that $\sigma\tau$ means "first τ, then σ". So ρ is a homomorphism, and each $\rho(\sigma)$ is invertible with inverse $\rho(\sigma^{-1})$. The matrix of $\rho(\sigma)$ in the standard basis is the permutation matrix $\mathbf{P}_\sigma$ of Definition 2.6.2. The same recipe works for any subgroup of S_n.
- **The rotation representation of $\mathbb{Z}/n\mathbb{Z}$ over $\mathbb{R}$.** $V = \mathbb{R}^2$ and $\rho([k])$ is rotation by $2\pi k/n$, with matrix $\begin{pmatrix} \cos(2\pi k/n) & -\sin(2\pi k/n) \\ \sin(2\pi k/n) & \cos(2\pi k/n) \end{pmatrix}$. Composing rotations adds angles, so $\rho([k])\rho([l]) = \rho([k+l])$; and rotating by $2\pi n/n = 2\pi$ is the identity, so the recipe does not depend on the representative k. For $n \geq 3$ this representation has no invariant line. A line invariant under $\rho([1])$ would give that matrix a real eigenvalue (Proposition 8.1.2), but with $c = \cos(2\pi/n)$ and $s = \sin(2\pi/n)$ its characteristic polynomial is $x^2 - 2cx + 1$, of discriminant $4c^2 - 4 = -4s^2$, which is negative because $0 < 2\pi/n < \pi$ forces $s \neq 0$ when $n \geq 3$. (The quarter-turn case is Example (A Rotation Has No Invariant Lines).) Section 04 turned this into the standard warning about Schur's lemma over $\mathbb{R}$.
- **The regular representation.** $V = F[G]$, the group algebra of Definition 22.1.5: the free vector space on the set G (Definition 14.2.3), with basis $\{\delta_g : g \in G\}$ and multiplication determined by $\delta_g\delta_h = \delta_{gh}$. Its dimension is $|G|$. Put $\rho_{\mathrm{reg}}(g)\delta_h = \delta_{gh}$, extended linearly. Then $\rho_{\mathrm{reg}}(g)\rho_{\mathrm{reg}}(g')\delta_h = \delta_{gg'h} = \rho_{\mathrm{reg}}(gg')\delta_h$, so ρ_{reg} is a homomorphism, and $\rho_{\mathrm{reg}}(g)$ is invertible with inverse $\rho_{\mathrm{reg}}(g^{-1})$. It is faithful: if $\rho_{\mathrm{reg}}(g) = \mathrm{id}$ then $\delta_g = \rho_{\mathrm{reg}}(g)\delta_1 = \delta_1$, so $g = 1$ because the δ_h are distinct basis vectors. Its degree is $|G|$.

Non-example by minimal change. Keep $V = F^2$ and $G = \mathbb{Z}/4\mathbb{Z}$, and try $\rho([k]) = \begin{pmatrix} 1 & k \\ 0 & 1 \end{pmatrix}$ over $\mathbb{Q}$. Each matrix is invertible, and $\rho([k])\rho([l]) = \begin{pmatrix} 1 & k+l \\ 0 & 1 \end{pmatrix}$, so multiplicativity holds on representatives. But the recipe is not **well defined** on $\mathbb{Z}/4\mathbb{Z}$: the class $[0]$ is also $[4]$, and $\begin{pmatrix} 1 & 4 \\ 0 & 1 \end{pmatrix} \neq \mathbf{I}_2$. The clause that fails is that ρ must be a function on G. Over $\mathbb{F}_2$ the same recipe on $\mathbb{Z}/2\mathbb{Z}$ *is* well defined, because $\begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} = \mathbf{I}_2$ there; we return to that example when Maschke's theorem breaks.

Warning. **A representation need not remember the group.** The trivial representation of any group is a representation, and it forgets everything. Conversely, a non-injective ρ can still be useful: the sign representation of S_n has a huge kernel yet separates even from odd permutations. When a statement needs ρ to see all of G, it must say **faithful**; none of the theorems below does.

Quick check. Is $\rho\colon \mathbb{Z}/3\mathbb{Z} \to \mathrm{GL}_1(\mathbb{R}) = \mathbb{R}\setminus\{0\}$, $\rho([k]) = (-1)^k$, a representation?

Solution. No: it is not well defined. We have $[0] = [3]$ in $\mathbb{Z}/3\mathbb{Z}$, but $(-1)^0 = 1$ while $(-1)^3 = -1$. Equivalently, a representation of degree 1 is a homomorphism $\mathbb{Z}/3\mathbb{Z} \to \mathbb{R}\setminus\{0\}$, and $\rho([1])^3 = \rho([0]) = 1$ forces $\rho([1]) = 1$, since 1 is the only real cube root of 1. So the only degree-1 real representation of $\mathbb{Z}/3\mathbb{Z}$ is the trivial one.

22.7.2 Subrepresentations, equivalence, and irreducibility

Having made operators, we ask the question this book always asks of a family of operators: can the space be broken into smaller pieces that the family preserves? Chapter 8 called such a piece an invariant subspace (Definition 8.1.1). Here the family is $\{\rho(g) : g \in G\}$.

Definition 22.7.2 — Subrepresentation

Let ρ be a representation of G on V. A subspace $U \subseteq V$ is **G-invariant** if $\rho(g)\mathbf{u} \in U$ **for every** $g \in G$ and every $\mathbf{u} \in U$. In that case the restrictions $\rho(g)|_U$ define a representation $\rho|_U$ of G on U, the **subrepresentation** of ρ on U.

Two checks make this legitimate. First, $\rho(g)|_U$ really is an operator **on** U, by invariance. Second, it is invertible on U: applying invariance to g^{-1} gives $\rho(g)^{-1}U = \rho(g^{-1})U \subseteq U$, so $\rho(g)|_U$ has a two-sided inverse on U, namely $\rho(g^{-1})|_U$. Multiplicativity is inherited. The subspaces $\{\mathbf{0}\}$ and V are always G-invariant; we call them the **trivial** invariant subspaces.

Definition 22.7.3 — Equivalence of representations

Let ρ and ρ' be representations of G on V and V', over the same field. A linear map $S\colon V \to V'$ **intertwines** ρ and ρ' if

$$S\,\rho(g) = \rho'(g)\,S \qquad \text{for every } g \in G.$$

The representations are **equivalent**, written $\rho \cong \rho'$, if some intertwining S is an isomorphism; equivalently, if $\rho'(g) = S\rho(g)S^{-1}$ for all g.

Equivalence is what "the same representation written in another basis" means. Indeed, if $V = V' = F^n$ and S is an invertible matrix, then $\rho'(g) = S\rho(g)S^{-1}$ is simultaneous similarity of the whole family $\{\rho(g)\}$ by one matrix. It is an equivalence relation: id_V intertwines ρ with itself; if S intertwines ρ with ρ' and is invertible then S^{-1} intertwines ρ' with ρ, since $S\rho(g) = \rho'(g)S$ gives $\rho(g)S^{-1} = S^{-1}\rho'(g)$; and a composition of intertwining isomorphisms intertwines.

Definition 22.7.4 — Irreducible representation

A representation ρ of G on V is **irreducible** if $V \neq \{\mathbf{0}\}$ and the only G-invariant subspaces of V are $\{\mathbf{0}\}$ and V. A representation with $V \neq \{\mathbf{0}\}$ that is not irreducible is **reducible**.

Read the two clauses separately. The zero space is excluded by decree, exactly as 1 is excluded from the primes: keeping it would break every statement of the form "every representation is built from irreducible ones". The second clause is the real content.

Examples and a non-example.

- Every representation of degree 1 is irreducible: a one-dimensional space has no subspaces but $\{\mathbf{0}\}$ and itself.
- The permutation representation of S_3 on F^3 is **reducible** for every F. The line $L = \operatorname{span}(\mathbf{e}_1+\mathbf{e}_2+\mathbf{e}_3)$ is S_3-invariant, since $\rho(\sigma)(\mathbf{e}_1+\mathbf{e}_2+\mathbf{e}_3) = \mathbf{e}_{\sigma(1)}+\mathbf{e}_{\sigma(2)}+\mathbf{e}_{\sigma(3)} = \mathbf{e}_1+\mathbf{e}_2+\mathbf{e}_3$, the same three basis vectors in another order. And $L \neq \{\mathbf{0}\}$, $L \neq F^3$.
- So is the **sum-zero** subspace $W = \{\mathbf{x} \in F^3 : x_1+x_2+x_3 = 0\}$, of dimension 2: permuting the coordinates of $\mathbf{x}$ does not change their sum. We will see below that over $\mathbb{C}$ the subrepresentation on W is irreducible; this is the **standard representation** of S_3.
- **Non-example by minimal change.** Replace S_3 by the subgroup $H = \{\mathrm{id}, (1\ 2)\} \subseteq S_3$ and keep $V = F^3$. Then $\operatorname{span}(\mathbf{e}_3)$ is H-invariant, though it is not S_3-invariant. Invariance depends on the whole group, not on one element of it.

Finally, the operation that puts representations together. If ρ_1, ρ_2 are representations of G on V_1, V_2, their **direct sum** is the representation $\rho_1 \oplus \rho_2$ on $V_1 \oplus V_2$ given by $(\rho_1 \oplus \rho_2)(g)(\mathbf{v}_1, \mathbf{v}_2) = (\rho_1(g)\mathbf{v}_1, \rho_2(g)\mathbf{v}_2)$. In a basis adapted to the decomposition its matrix is block diagonal, $\rho_1(g) \oplus \rho_2(g)$. Conversely, if $V = U \oplus W$ with both summands G-invariant, then the map $U \oplus W \to V$, $(\mathbf{u}, \mathbf{w}) \mapsto \mathbf{u} + \mathbf{w}$, is an isomorphism intertwining $\rho|_U \oplus \rho|_W$ with ρ, so $\rho \cong \rho|_U \oplus \rho|_W$. So "decomposing a representation" and "finding an invariant complement" are the same task.

22.7.3 Representations of G and representations of $F[G]$

Here is the bridge that puts Sections 01–06 to work. The group algebra $F[G]$ was built in Definition 22.1.5 precisely so that the next theorem is true.

Theorem 22.7.1 — Representations of G are representations of $F[G]$

Let G be a finite group, F a field and V a finite-dimensional vector space over F. The assignment

$$\rho \longmapsto \widetilde{\rho}, \qquad \widetilde{\rho}\Big(\sum_{g\in G} a_g \delta_g\Big) := \sum_{g\in G} a_g\, \rho(g),$$

is a bijection from the set of representations $\rho\colon G \to \mathrm{GL}(V)$ onto the set of algebra homomorphisms $F[G] \to \mathrm{End}(V)$ (Definition 22.1.2) — that is, onto the ways of making

V an $F[G]$-space in the sense of Definition 22.3.2. Moreover a subspace $U \subseteq V$ is G-invariant for ρ if and only if $\widetilde{\rho}(a)U \subseteq U$ for every $a \in F[G]$.

Idea. An element of $F[G]$ is a formal linear combination of group elements, so a linear map out of $F[G]$ is determined by, and may be prescribed freely on, the basis $\{\delta_g\}$. The only thing to check is that "multiplicative on the basis" upgrades to "multiplicative everywhere", and that is bilinearity of both products. The inverse map recovers ρ by restricting to the basis; the one point needing care is why $\widetilde{\rho}(\delta_g)$ is automatically **invertible**, which is where $\delta_g\delta_{g^{-1}} = \delta_1$ earns its keep.

Proof. Let $\rho\colon G \to \mathrm{GL}(V)$ be a representation. The formula defines a linear map $\widetilde{\rho}\colon F[G] \to \mathrm{End}(V)$, because $\{\delta_g\}$ is a basis of $F[G]$ and a linear map may be prescribed on a basis (Theorem 3.1.6). It sends δ_1 to $\rho(1) = \mathrm{id}_V$ (Theorem 0.10.3). For multiplicativity, take $a = \sum_g a_g\delta_g$ and $b = \sum_h b_h\delta_h$. Multiplication in $F[G]$ and composition in $\mathrm{End}(V)$ are both bilinear, so

$$\begin{aligned}\widetilde{\rho}(ab) &= \widetilde{\rho}\Big(\sum_{g,h} a_g b_h\,\delta_{gh}\Big) = \sum_{g,h} a_g b_h\,\rho(gh)\\ &= \sum_{g,h} a_g b_h\,\rho(g)\rho(h) = \Big(\sum_g a_g\rho(g)\Big)\Big(\sum_h b_h\rho(h)\Big) = \widetilde{\rho}(a)\widetilde{\rho}(b),\end{aligned}$$

where the third equality is the homomorphism property of ρ. Hence $\widetilde{\rho}$ is an algebra homomorphism.

Conversely, let $\varphi\colon F[G] \to \mathrm{End}(V)$ be an algebra homomorphism, and set $\rho(g) \coloneqq \varphi(\delta_g)$. Since δ_1 is the identity of $F[G]$ (Definition 22.1.5) and id_V is the identity of $\mathrm{End}(V)$, the unital clause of Definition 22.1.2 gives $\varphi(\delta_1) = \mathrm{id}_V$. Then $\rho(g)\rho(h) = \varphi(\delta_g\delta_h) = \varphi(\delta_{gh}) = \rho(gh)$. In particular $\rho(g)\rho(g^{-1}) = \varphi(\delta_1) = \mathrm{id}_V$ and likewise in the other order, so each $\rho(g)$ is invertible and ρ maps into $\mathrm{GL}(V)$. Thus ρ is a representation, and $\widetilde{\rho} = \varphi$ because the two agree on the basis $\{\delta_g\}$ and both are linear. Since also $\widetilde{\rho}(\delta_g) = \rho(g)$, the two constructions are mutually inverse, and the assignment is a bijection.

For the last sentence, suppose U is G-invariant. For $a = \sum_g a_g\delta_g$ and $\mathbf{u} \in U$, each $\rho(g)\mathbf{u}$ lies in U, and U is a subspace, so $\widetilde{\rho}(a)\mathbf{u} = \sum_g a_g\rho(g)\mathbf{u} \in U$. Conversely, if $\widetilde{\rho}(a)U \subseteq U$ for all a, take $a = \delta_g$. This proves the theorem.

∎

So the two languages are interchangeable, and we use whichever is shorter. A G-invariant subspace is an $F[G]$-invariant subspace; an irreducible representation of G on V is exactly a simple $F[G]$-space in the sense of Definition 22.3.3; and a map intertwining two representations of G is exactly an $F[G]$-map in the sense of Definition 22.4.1, since the condition $S\rho(g) = \rho'(g)S$ for all g extends by linearity to all of $F[G]$. In particular Schur's lemma (Theorem 22.4.1) applies verbatim to irreducible representations of groups, and we use it that way in Section 08.

Remark. Working with $F[G]$ rather than with G buys one thing that matters: the ability to **add** group elements. Every averaging argument below lives in $F[G]$, not in G. Chapter 9 §07 made the same move for a single operator, replacing T by the algebra $F[T]$ and the space by an $F[x]$-module.

22.7.4 Maschke's theorem

We now know that a reducible representation has a proper non-zero invariant subspace U. To break V into pieces we need more: an invariant **complement**, a G-invariant W with $V = U \oplus W$. An ordinary complement always exists (Theorem 1.7.6), but it has no reason to be invariant.

The idea for repairing it is the one move this chapter uses over and over. Start with an object that is not invariant, and average its G-translates. The average is invariant because translating it permutes the terms of the sum. Averaging divides by $|G|$, and that is the whole hypothesis.

Lemma 22.7.2 — When the group order is invertible

Let F be a field and m a positive integer. Then $m \cdot 1_F \neq 0$ in F if and only if $\operatorname{char} F$ does not divide m.

Proof. If $\operatorname{char} F = 0$, then $m \cdot 1_F \neq 0$ for every positive integer m (Definition 0.7.2), and 0 divides no positive integer, so both sides of the equivalence hold. Assume from now on that $p \coloneqq \operatorname{char} F > 0$, so p is the **smallest** positive integer with $p \cdot 1_F = 0$.

($\Rightarrow$) We prove the contrapositive: if $p \mid m$, then $m \cdot 1_F = 0$. Write $m = qp$ with $q \geq 1$. By Lemma 0.7.4, $m \cdot 1_F = (qp) \cdot 1_F = (q \cdot 1_F)(p \cdot 1_F) = (q \cdot 1_F) \cdot 0 = 0$.

($\Leftarrow$) Suppose, for a contradiction, that some positive integer m has $m \cdot 1_F = 0$ and $p \nmid m$. Choose such an m as small as possible. Now $m \neq p$, since $p \mid p$, and $m > p$, since p is the smallest positive integer killing 1_F. So $m - p$ is a positive integer, and by Lemma 0.7.4

$$(m - p) \cdot 1_F + p \cdot 1_F = m \cdot 1_F = 0,$$

whence $(m - p) \cdot 1_F = 0$. Also $p \nmid m - p$, for otherwise p would divide $(m - p) + p = m$. This contradicts the minimality of m. This proves the lemma.

■

Theorem 22.7.3 — Maschke's Theorem

Let G be a **finite** group and F a field whose characteristic does **not** divide $|G|$. Let ρ be a representation of G on a finite-dimensional space V over F, and let $U \subseteq V$ be a G-invariant subspace. Then there is a G-invariant subspace $W \subseteq V$ with

$$V = U \oplus W.$$

Idea. Pick **any** projection P of V onto U; its kernel is a complement, but the wrong one, because P need not commute with the $\rho(g)$. Repair it by averaging the conjugates $\rho(g)P\rho(g)^{-1}$ over $g \in G$. ① Each conjugate is again a projection onto U, because U is invariant. ② Their average P_0 is therefore again a projection onto U — here we divide by $|G|$. ③ Conjugating P_0 by $\rho(h)$ only permutes the terms of the sum, so P_0 commutes with every $\rho(h)$, and then its kernel is invariant.

Proof. Write $n = |G|$. By hypothesis and Lemma 22.7.2, $n \cdot 1_F \neq 0$, so the scalar $\frac{1}{n} \coloneqq (n \cdot 1_F)^{-1}$ exists in F. By Theorem 1.7.6 there is a subspace W_0 with $V = U \oplus W_0$;

let $P \in \mathcal{L}(V)$ be the projection onto U along W_0 (Theorem 3.10.1 (b)), so $\operatorname{im} P = U$ and $P\mathbf{u} = \mathbf{u}$ for all $\mathbf{u} \in U$. Define

$$P_0 \coloneqq \frac{1}{n} \sum_{g \in G} \rho(g)\, P\, \rho(g)^{-1} \ \in \mathcal{L}(V).$$

Step 1: $\operatorname{im} P_0 \subseteq U$. Let $\mathbf{v} \in V$ and $g \in G$. Then $P\rho(g)^{-1}\mathbf{v} \in \operatorname{im} P = U$, and U is G-invariant, so $\rho(g)P\rho(g)^{-1}\mathbf{v} \in U$. A subspace is closed under sums and scalar multiples, so $P_0\mathbf{v} \in U$.

Step 2: $P_0\mathbf{u} = \mathbf{u}$ for $\mathbf{u} \in U$. Let $\mathbf{u} \in U$ and $g \in G$. Since U is G-invariant and $\rho(g)^{-1} = \rho(g^{-1})$, we have $\rho(g)^{-1}\mathbf{u} \in U$, so $P\rho(g)^{-1}\mathbf{u} = \rho(g)^{-1}\mathbf{u}$ and hence $\rho(g)P\rho(g)^{-1}\mathbf{u} = \mathbf{u}$. Summing over the n elements of G gives $\sum_g \rho(g)P\rho(g)^{-1}\mathbf{u} = (n \cdot 1_F)\mathbf{u}$, and multiplying by $\frac{1}{n}$ gives $P_0\mathbf{u} = \mathbf{u}$.

By Steps 1 and 2, $P_0\mathbf{v} \in U$ for every $\mathbf{v}$, and P_0 fixes U pointwise; therefore $P_0^2\mathbf{v} = P_0(P_0\mathbf{v}) = P_0\mathbf{v}$, so P_0 is a projection (Definition 3.10.1) with $\operatorname{im} P_0 = U$.

Step 3: P_0 commutes with every $\rho(h)$. Fix $h \in G$. Then

$$\rho(h)P_0\rho(h)^{-1} = \frac{1}{n} \sum_{g \in G} \rho(hg)\, P\, \rho(hg)^{-1},$$

using $\rho(h)\rho(g) = \rho(hg)$ and $\rho(g)^{-1}\rho(h)^{-1} = (\rho(h)\rho(g))^{-1} = \rho(hg)^{-1}$. The map $g \mapsto hg$ is a bijection $G \to G$, with inverse $g \mapsto h^{-1}g$ by Theorem 0.10.1, so as g runs over G so does hg, and the sum is unchanged: $\rho(h)P_0\rho(h)^{-1} = P_0$. Multiplying on the right by $\rho(h)$ gives $\rho(h)P_0 = P_0\rho(h)$.

Step 4: conclusion. Put $W \coloneqq \ker P_0$. By Theorem 3.10.1 (a), $V = \operatorname{im} P_0 \oplus \ker P_0 = U \oplus W$. And W is G-invariant: if $P_0\mathbf{w} = \mathbf{0}$ and $h \in G$, then by Step 3, $P_0\rho(h)\mathbf{w} = \rho(h)P_0\mathbf{w} = \mathbf{0}$, so $\rho(h)\mathbf{w} \in W$. This proves the theorem.

■

Two hypotheses did real work, and it is worth naming where. **Finiteness** of G is what makes the sum $\sum_g$ a finite sum, hence an operator at all. The condition on the **characteristic** is what makes $\frac{1}{n}$ exist, and Step 2 is where it is spent: without the division, the computation in Step 2 gives $\sum_g \rho(g)P\rho(g)^{-1}\mathbf{u} = (n \cdot 1_F)\mathbf{u}$, which is $\mathbf{0}$ for every $\mathbf{u} \in U$ when $\operatorname{char} F$ divides n. The unnormalized sum then **annihilates** U instead of fixing it, and there is nothing to rescue. Both failures are real, not artifacts of the proof.

Example. (Maschke fails when the characteristic divides the order)

Let p be a prime, $F = \mathbb{F}_p$, $G = \mathbb{Z}/p\mathbb{Z}$ and $V = \mathbb{F}_p^2$. Define

$$\rho([k]) \coloneqq \begin{pmatrix} 1 & k \\ 0 & 1 \end{pmatrix} \in \mathrm{GL}_2(\mathbb{F}_p).$$

Show that ρ is a well-defined representation, that $U = \operatorname{span}(\mathbf{e}_1)$ is G-invariant, and that U has **no** G-invariant complement.

Solution. *Well defined.* The entry k is read in $\mathbb{F}_p$, so the matrix depends only on k modulo p; and $\left(\begin{smallmatrix}1 & k\\ 0 & 1\end{smallmatrix}\right)\left(\begin{smallmatrix}1 & l\\ 0 & 1\end{smallmatrix}\right) = \left(\begin{smallmatrix}1 & k+l\\ 0 & 1\end{smallmatrix}\right)$, so $\rho([k])\rho([l]) = \rho([k]+[l])$. Each matrix is invertible, with inverse $\rho([-k])$. So ρ is a representation of the additive group $\mathbb{Z}/p\mathbb{Z}$. Here $|G| = p = \operatorname{char}\mathbb{F}_p$, so the characteristic **does** divide the order and the hypothesis of Theorem 22.7.3 fails.

The invariant line. $\rho([k])\mathbf{e}_1 = \mathbf{e}_1$ for every k, so $U = \operatorname{span}(\mathbf{e}_1)$ is G-invariant, and $U \neq \{\mathbf{0}\}, V$.

No invariant complement. If $V = U \oplus W$, then $\dim W = 2 - 1 = 1$ by Theorem 1.7.3, so $W = \operatorname{span}(\mathbf{v})$ for some $\mathbf{v} = (a, b) \neq \mathbf{0}$; and $b \neq 0$, since $b = 0$ would force $a \neq 0$ and $W = \operatorname{span}(\mathbf{e}_1) = U$, which is not a complement of itself. Suppose W is G-invariant. Then $\rho([1])\mathbf{v} = (a + b,\, b)$ must be a scalar multiple $\lambda\mathbf{v} = (\lambda a, \lambda b)$. Comparing second coordinates and dividing by $b \neq 0$ gives $\lambda = 1$; comparing first coordinates then gives $a + b = a$, so $b = 0$, a contradiction. Hence U has no G-invariant complement. In fact U is the **only** non-trivial invariant subspace, so V is neither irreducible nor a direct sum of irreducibles.

Warning. **Do not drop finiteness either.** Let $G = \mathbb{Z}$ (infinite) act on $\mathbb{Q}^2$ by $\rho(k) = \left(\begin{smallmatrix}1 & k\\ 0 & 1\end{smallmatrix}\right)$ — now well defined, since $\mathbb{Z}$ has no relations to respect. The computation just made, with $b \neq 0$ in $\mathbb{Q}$, again shows $\operatorname{span}(\mathbf{e}_1)$ is invariant with no invariant complement, and here the characteristic is 0. Averaging over $\mathbb{Z}$ is not an option: the sum has infinitely many terms.

Once one invariant complement can always be found, the full decomposition follows by induction.

Corollary 22.7.4 — Complete Reducibility of Group Representations

Let G be a finite group and F a field with $\operatorname{char} F \nmid |G|$ — for instance $F = \mathbb{C}$. Then every representation ρ of G on a non-zero finite-dimensional space V over F decomposes as

$$V = V_1 \oplus V_2 \oplus \cdots \oplus V_r$$

with each V_i a G-invariant subspace on which the subrepresentation is irreducible.

Proof. We argue by strong induction on $\dim V \geq 1$ (Theorem 0.2.10). If ρ is irreducible, take $r = 1$ and $V_1 = V$. Otherwise V has a G-invariant subspace U with $U \neq \{\mathbf{0}\}$ and $U \neq V$. By Theorem 22.7.3 there is a G-invariant W with $V = U \oplus W$, and $W \neq \{\mathbf{0}\}$ since $U \neq V$. Both $\dim U$ and $\dim W$ are at least 1, and since $U \cap W = \{\mathbf{0}\}$ (Theorem 1.7.4) the dimension formula Theorem 1.7.3 gives $\dim U + \dim W = \dim V$; hence both are smaller than $\dim V$. The induction hypothesis decomposes U and W into irreducible invariant subspaces, and concatenating the two lists decomposes V, because a subspace of U invariant under $\rho|_U$ is invariant under ρ. This proves the corollary. ∎

In the language of Section 03, the corollary says that $F[G]$ acts semisimply on every representation (Definition 22.3.4, Theorem 22.3.3); applied to the regular representation, it says $F[G]$ is a semisimple algebra. Section 06's structure theorem then applies to $\mathbb{C}[G]$, and Section 08 cashes that in.

Quick check. Where exactly does the proof of Corollary 22.7.4 use that $V \neq \{\mathbf{0}\}$?

Solution. In the base of the induction and in the meaning of the conclusion. If $V = \{\mathbf{0}\}$ it is not irreducible (Definition 22.7.4 excludes the zero space) and it has no non-zero invariant subspace to split off, so neither branch of the argument applies. The usual convention is that $\{\mathbf{0}\}$ is the empty direct sum, $r = 0$; the corollary is stated with $V \neq \{\mathbf{0}\}$ so that $r \geq 1$.

22.7.5 Two families worked out

We close with the two examples Section 08 will compute characters for. Both are over $\mathbb{C}$, where Corollary 22.7.4 applies to every finite group.

Example. (The irreducible complex representations of a cyclic group)

Let $G = \mathbb{Z}/n\mathbb{Z}$ and $F = \mathbb{C}$. Determine all irreducible representations of G up to equivalence.

Solution. Every irreducible is one-dimensional. Let ρ be a representation of G on $V \neq \{\mathbf{0}\}$ over $\mathbb{C}$, and set $A = \rho([1])$. By Theorem 8.2.4, A has an eigenvector $\mathbf{v} \neq \mathbf{0}$, say $A\mathbf{v} = \lambda\mathbf{v}$. The line $L = \operatorname{span}(\mathbf{v})$ is invariant under A, hence under every power $A^k = \rho([k])$, so L is G-invariant. If ρ is irreducible then $L = V$, so $\dim V = 1$. (For abelian G the algebra $\mathbb{C}[G]$ is commutative, since $\delta_g\delta_h = \delta_{gh} = \delta_{hg} = \delta_h\delta_g$ and multiplication is bilinear; so this is also Corollary 22.4.4 read through Theorem 22.7.1.)

Listing them. A one-dimensional representation is a homomorphism $\chi\colon \mathbb{Z}/n\mathbb{Z} \to \mathbb{C}\setminus\{0\}$, determined by $z = \chi([1])$, which must satisfy $z^n = \chi([n]) = \chi([0]) = 1$. So z is an n-th root of unity, $z = \omega^k$ with $\omega = e^{2\pi i/n}$ and $0 \leq k \leq n-1$ (Example (Roots of Unity)). Conversely each such z does define a homomorphism $\chi_k([j]) = \omega^{jk}$: the recipe respects representatives because $\omega^n = 1$, and $\omega^{(j+l)k} = \omega^{jk}\omega^{lk}$.

They are pairwise inequivalent. Two one-dimensional representations are equivalent exactly when they are equal, since on a one-dimensional space every operator is $\lambda\,\mathrm{id}$ for a scalar λ, and $S(\lambda\,\mathrm{id})S^{-1} = \lambda\,\mathrm{id}$ for every isomorphism S. And $\chi_k \neq \chi_l$ for $0 \leq k < l \leq n-1$, because $\chi_k([1]) = \omega^k \neq \omega^l = \chi_l([1])$, the n-th roots of unity being distinct.

So $\mathbb{Z}/n\mathbb{Z}$ has exactly n irreducible complex representations, all of degree 1, namely $\chi_0, \ldots, \chi_{n-1}$. Their degrees satisfy $\sum_k 1^2 = n = |G|$, the count Corollary 22.6.2 gives for the semisimple algebra $\mathbb{C}[G]$.

Example. (The irreducible complex representations of the symmetric group on three letters)

Write down three pairwise inequivalent irreducible complex representations of S_3, with explicit matrices for the two-dimensional one.

Solution. Trivial and sign. $\rho_{\mathrm{triv}}(\sigma) = 1$ and $\rho_{\mathrm{sgn}}(\sigma) = \operatorname{sgn}(\sigma)$, both on $\mathbb{C}$, both irreducible because their degree is 1. They are inequivalent: $\rho_{\mathrm{triv}}((1\ 2)) = 1 \neq -1 = \rho_{\mathrm{sgn}}((1\ 2))$.

The standard representation. Take the permutation representation on $\mathbb{C}^3$ and restrict it to the invariant plane $W = \{\mathbf{x} : x_1 + x_2 + x_3 = 0\}$. A basis of W is $\mathcal{B} = (\mathbf{f}_1, \mathbf{f}_2)$ with $\mathbf{f}_1 = \mathbf{e}_1 - \mathbf{e}_2$ and $\mathbf{f}_2 = \mathbf{e}_2 - \mathbf{e}_3$: they lie in W, they are independent, and $\dim W = 2$ because W is the kernel of the surjective functional $\mathbf{x} \mapsto x_1 + x_2 + x_3$ on $\mathbb{C}^3$ (Theorem 3.3.1). Since S_3 is generated by $(1\ 2)$ and $(1\ 2\ 3)$ — every element of S_3 is a product of transpositions (Theorem 0.10.4), and $(1\ 3) = (1\ 2\ 3)(1\ 2)$, $(2\ 3) = (1\ 2)(1\ 2\ 3)$ — it is enough to record two matrices. With $\rho(\sigma)\mathbf{e}_i = \mathbf{e}_{\sigma(i)}$:

$$\begin{aligned} \rho((1\ 2))\mathbf{f}_1 &= \mathbf{e}_2 - \mathbf{e}_1 = -\mathbf{f}_1, \\ \rho((1\ 2))\mathbf{f}_2 &= \mathbf{e}_1 - \mathbf{e}_3 = \mathbf{f}_1 + \mathbf{f}_2, \\ \rho((1\ 2\ 3))\mathbf{f}_1 &= \mathbf{e}_2 - \mathbf{e}_3 = \mathbf{f}_2, \\ \rho((1\ 2\ 3))\mathbf{f}_2 &= \mathbf{e}_3 - \mathbf{e}_1 = -\mathbf{f}_1 - \mathbf{f}_2. \end{aligned}$$

Writing $R_\sigma \coloneqq \rho(\sigma)|_W$, the two matrices in the basis $\mathcal{B}$ are

$$[R_{(1\ 2)}]^{\mathcal{B}}_{\mathcal{B}} = \begin{pmatrix} -1 & 1 \\ 0 & 1 \end{pmatrix}, \qquad [R_{(1\ 2\ 3)}]^{\mathcal{B}}_{\mathcal{B}} = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}.$$

The remaining four matrices follow by multiplying: $\mathbf{I}_2$ for id, $\left(\begin{smallmatrix} 0 & -1 \\ -1 & 0 \end{smallmatrix}\right)$ for $(1\ 3)$, $\left(\begin{smallmatrix} 1 & 0 \\ 1 & -1 \end{smallmatrix}\right)$ for $(2\ 3)$ and $\left(\begin{smallmatrix} -1 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ for $(1\ 3\ 2)$.

Irreducibility. A proper non-zero invariant subspace of the plane W would be a line $\operatorname{span}(\mathbf{v})$, and $\mathbf{v}$ would be an eigenvector of **both** displayed matrices. The first has eigenvalues -1 and 1, with eigenvectors spanned by $(1, 0)$ and $(1, 2)$ respectively. The second has characteristic polynomial $x^2 + x + 1$, whose roots are the two primitive cube roots of unity; neither $(1, 0)$ nor $(1, 2)$ is an eigenvector of it, since $\left(\begin{smallmatrix} 0 & -1 \\ 1 & -1 \end{smallmatrix}\right)(1, 0) = (0, 1)$ and $\left(\begin{smallmatrix} 0 & -1 \\ 1 & -1 \end{smallmatrix}\right)(1, 2) = (-2, -1)$ are not multiples of $(1, 0)$, $(1, 2)$. So there is no common eigenvector, and the standard representation is irreducible.

Inequivalent. It has degree 2, the others degree 1, and equivalent representations act on spaces of the same dimension.

The degrees satisfy $1^2 + 1^2 + 2^2 = 6 = |S_3|$, which is the count Corollary 22.6.2 gives for the semisimple algebra $\mathbb{C}[S_3]$. That count runs over **all** isomorphism classes of irreducible $\mathbb{C}[S_3]$-spaces (Theorem 22.6.1), and a further class would add at least 1 to a total already equal to 6; so these three are all of the irreducible complex representations of S_3. Section 08 reaches the same conclusion by counting conjugacy classes, which does not require the list to be found first.

22.7.6 Exercises

22.7.6.1 A. Check your understanding

Exercise A1.

(a) State the definition of a representation of a group G on a vector space V, and say which two properties of ρ come for free.

(b) State Maschke's theorem with all of its hypotheses.

(c) Determine whether the following is true: "every representation of degree 1 is irreducible." Justify your answer.

(d) Give an example of a reducible representation of S_3 over $\mathbb{C}$, and name an invariant subspace.

(e) Explain why $\rho\colon \mathbb{Z}/2\mathbb{Z} \to \mathrm{GL}_1(\mathbb{Q})$, $\rho([k]) = 2^k$, is **not** a representation.

Solution.

(a) A representation is a group homomorphism $\rho\colon G \to \mathrm{GL}(V)$ with V finite-dimensional over F, that is, $\rho(gh) = \rho(g)\rho(h)$ for all $g, h \in G$ with each $\rho(g)$ invertible (Definition 22.7.1). Free: $\rho(1) = \mathrm{id}_V$ and $\rho(g^{-1}) = \rho(g)^{-1}$, by Theorem 0.10.3.

(b) If G is finite, F is a field with $\operatorname{char} F \nmid |G|$, V is finite-dimensional over F and $U \subseteq V$ is G-invariant, then U has a G-invariant complement W, so $V = U \oplus W$ (Theorem 22.7.3).

(c) True. If $\dim V = 1$ then $V \neq \{\mathbf{0}\}$ and the only subspaces of V are $\{\mathbf{0}\}$ and V, so in particular the only invariant ones are the trivial ones.

(d) The permutation representation of S_3 on $\mathbb{C}^3$; the line $\operatorname{span}(\mathbf{e}_1+\mathbf{e}_2+\mathbf{e}_3)$ is invariant, as is the sum-zero plane.

(e) It is not well defined: $[0] = [2]$ in $\mathbb{Z}/2\mathbb{Z}$, but $2^0 = 1 \neq 4 = 2^2$. (Equivalently, a degree-1 representation of $\mathbb{Z}/2\mathbb{Z}$ needs $\rho([1])^2 = 1$, and the only rational solutions of $z^2 = 1$ are $z = \pm 1$.)

22.7.6.2 B. Practice

Exercise B1: Which of these are representations?.

Determine which of the following are representations. Justify your answer in each case.

(a) $G = \mathbb{Z}/6\mathbb{Z}$, $F = \mathbb{C}$, $\rho([k]) = \begin{pmatrix} \omega^k & 0 \\ 0 & \omega^{-k} \end{pmatrix}$ with $\omega = e^{\pi i/3}$.

(b) $G = S_3$, $F = \mathbb{R}$, $\rho(\sigma) = \operatorname{sgn}(\sigma)\,\mathbf{P}_\sigma$, where $\mathbf{P}_\sigma$ is the permutation matrix with $\mathbf{P}_\sigma \mathbf{e}_i = \mathbf{e}_{\sigma(i)}$ (Definition 2.6.2).

(c) $G = S_3$, $F = \mathbb{R}$, $\rho(\sigma) = \mathbf{P}_\sigma^{\top}$ with $\mathbf{P}_\sigma$ as in (b).

(d) $G = \mathbb{Z}/4\mathbb{Z}$, $F = \mathbb{R}$, $\rho([k]) = \begin{pmatrix} 1 & 0 \\ 0 & k+1 \end{pmatrix}$.

Solution.

(a) Yes. Here $\omega^6 = e^{2\pi i} = 1$, so the matrix depends only on k modulo 6 and the map is well defined; it is diagonal, hence invertible since $\omega^{\pm k} \neq 0$; and $\rho([k])\rho([l]) = \operatorname{diag}(\omega^{k+l}, \omega^{-k-l}) = \rho([k]+[l])$.

(b) Yes. Both factors are multiplicative: $\operatorname{sgn}(\sigma\tau) = \operatorname{sgn}(\sigma)\operatorname{sgn}(\tau)$ (Theorem 6.3.1) and $\mathbf{P}_\sigma\mathbf{P}_\tau = \mathbf{P}_{\sigma\tau}$ (Lemma 2.6.6 (a)). Scalars commute with matrices, so $\rho(\sigma)\rho(\tau) = \operatorname{sgn}(\sigma\tau)\mathbf{P}_{\sigma\tau} = \rho(\sigma\tau)$, and $\rho(\sigma)$ is invertible because $\mathbf{P}_\sigma$ is and $\operatorname{sgn}(\sigma) \neq 0$.

(c) No. Taking transposes reverses products: $\rho(\sigma)\rho(\tau) = \mathbf{P}_\sigma^{\top}\mathbf{P}_\tau^{\top} = (\mathbf{P}_\tau\mathbf{P}_\sigma)^{\top} = \mathbf{P}_{\tau\sigma}^{\top} = \rho(\tau\sigma)$. Since S_3 is not abelian this differs from $\rho(\sigma\tau)$: with $\sigma = (1\ 2)$, $\tau = (1\ 3)$ we get $\tau\sigma = (1\ 2\ 3) \neq (1\ 3\ 2) = \sigma\tau$ (Example (Computing with cycles)), and distinct permutations have distinct permutation matrices. (The repair is $\sigma \mapsto \mathbf{P}_{\sigma^{-1}}^{\top}$, or equivalently $\mathbf{P}_\sigma$ itself.)

(d) No, on two counts. It is not well defined: $[0] = [4]$ but $\operatorname{diag}(1,1) \neq \operatorname{diag}(1,5)$.

And it is not multiplicative even on representatives: $\rho([1])\rho([1]) = \operatorname{diag}(1,4)$ while $\rho([2]) = \operatorname{diag}(1,3)$.

Exercise B2: Averaging an inner product.

Let G be a finite group and ρ a representation of G on a complex space V carrying an inner product $\langle \cdot,\cdot\rangle$ (Definition 10.1.1). Define

$$\langle \mathbf{u},\mathbf{v}\rangle_G := \frac{1}{|G|}\sum_{g\in G}\langle \rho(g)\mathbf{u},\rho(g)\mathbf{v}\rangle.$$

Prove that $\langle\cdot,\cdot\rangle_G$ is an inner product on V and that every $\rho(g)$ is an isometry for it. Hence give a second proof of Theorem 22.7.3 over $\mathbb{C}$.

Solution. (IP1). For fixed $\mathbf{v}$, the map $\mathbf{u}\mapsto\langle\rho(g)\mathbf{u},\rho(g)\mathbf{v}\rangle$ is linear in $\mathbf{u}$, being a composition of the linear map $\rho(g)$ with a slot that is linear by (IP1) for $\langle\cdot,\cdot\rangle$. A sum of linear maps times a scalar is linear.

(IP2). $\langle \mathbf{v},\mathbf{u}\rangle_G = \frac{1}{|G|}\sum_g\langle\rho(g)\mathbf{v},\rho(g)\mathbf{u}\rangle = \frac{1}{|G|}\sum_g\overline{\langle\rho(g)\mathbf{u},\rho(g)\mathbf{v}\rangle} = \overline{\langle\mathbf{u},\mathbf{v}\rangle_G}$, since conjugation is additive.

(IP3). For $\mathbf{v}\neq\mathbf{0}$, each $\rho(g)\mathbf{v}\neq\mathbf{0}$ because $\rho(g)$ is invertible, so each term $\langle\rho(g)\mathbf{v},\rho(g)\mathbf{v}\rangle$ is >0, and $|G|>0$ is a positive real. Hence $\langle\mathbf{v},\mathbf{v}\rangle_G>0$.

Isometry. For $h\in G$, $\langle\rho(h)\mathbf{u},\rho(h)\mathbf{v}\rangle_G = \frac{1}{|G|}\sum_g\langle\rho(gh)\mathbf{u},\rho(gh)\mathbf{v}\rangle = \langle\mathbf{u},\mathbf{v}\rangle_G$, because $g\mapsto gh$ is a bijection of G (Theorem 0.10.1).

Second proof of Maschke over $\mathbb{C}$. Let U be G-invariant and let $W=U^{\perp}$ be its orthogonal complement for $\langle\cdot,\cdot\rangle_G$. Then $V=U\oplus W$ by Theorem 10.3.2. If $\mathbf{w}\in W$, $\mathbf{u}\in U$ and $h\in G$, then, writing $\mathbf{u}=\rho(h)\big(\rho(h)^{-1}\mathbf{u}\big)$ and using that $\rho(h)$ preserves $\langle\cdot,\cdot\rangle_G$,

$$\langle\rho(h)\mathbf{w},\mathbf{u}\rangle_G = \langle\rho(h)\mathbf{w},\rho(h)\rho(h)^{-1}\mathbf{u}\rangle_G = \langle\mathbf{w},\rho(h)^{-1}\mathbf{u}\rangle_G = 0,$$

the last step because $\rho(h)^{-1}\mathbf{u}=\rho(h^{-1})\mathbf{u}\in U$ and $\mathbf{w}\in U^{\perp}$. So $\rho(h)\mathbf{w}\in W$, and W is G-invariant. Note that this route needs $F=\mathbb{R}$ or $\mathbb{C}$, where inner products live, whereas Theorem 22.7.3 needs only a condition on the characteristic.

Exercise B3: Decomposing a permutation representation.

Number the coordinates of $\mathbb{C}^3$ as $0,1,2$, as in Chapter 11 §09, and let $G=\mathbb{Z}/3\mathbb{Z}$ act by $\rho([k])=\mathbf{S}^k$, where $\mathbf{S}$ is the cyclic shift, $\mathbf{Sx}=(x_1,x_2,x_0)$. Check that ρ is a representation, decompose $\mathbb{C}^3$ into one-dimensional invariant subspaces, and identify each with one of the χ_k of Example (The irreducible complex representations of a cyclic group).

Solution. A representation. Shifting three times restores every entry, so $\mathbf{S}^3=\mathbf{I}$, and therefore $\mathbf{S}^k$ depends only on k modulo 3: the recipe is well defined on $\mathbb{Z}/3\mathbb{Z}$. It is multiplicative because $\mathbf{S}^k\mathbf{S}^l=\mathbf{S}^{k+l}$, and each $\mathbf{S}^k$ is invertible with inverse $\mathbf{S}^{3-k}$.

Decomposition. Let $\omega=e^{2\pi i/3}$. By Theorem 11.9.2 the vectors $\mathbf{f}_j=\frac{1}{\sqrt{3}}(1,\omega^j,\omega^{2j})$, $j=0,1,2$, satisfy $\mathbf{S}\mathbf{f}_j=\omega^j\mathbf{f}_j$. The three eigenvalues $1,\omega,\omega^2$ are distinct, so the $\mathbf{f}_j$

are independent (Theorem 8.2.2), and three independent vectors in $\mathbb{C}^3$ form a basis (Theorem 1.6.4). Hence

$$\mathbb{C}^3 = \operatorname{span}(\mathbf{f}_0) \oplus \operatorname{span}(\mathbf{f}_1) \oplus \operatorname{span}(\mathbf{f}_2),$$

and each line is invariant under $\mathbf{S}$, hence under every $\rho([k]) = \mathbf{S}^k$.

Identification. On $\operatorname{span}(\mathbf{f}_j)$ the element $[k]$ acts by the scalar ω^{jk}, which is exactly $\chi_j([k])$ in the notation of Example (The irreducible complex representations of a cyclic group). So the three summands realize χ_0, χ_1, χ_2: every irreducible representation of $\mathbb{Z}/3\mathbb{Z}$ occurs exactly once.

22.7.6.3 C. Going deeper

Exercise C1: One-dimensional representations and the commutator.

Let G be a finite group and F a field.

(a) Prove that every representation of degree 1 satisfies $\rho(ghg^{-1}h^{-1}) = 1$ for all $g, h \in G$.

(b) Deduce that the only degree-1 complex representation of $G = S_3$ other than the trivial one is the sign representation. *Hint: write the* 3*-cycle* $(1\ 2\ 3)$ *in the form* $ghg^{-1}h^{-1}$ *with* g *and* h *transpositions.*

Solution.

(a) A degree-1 representation takes values in $F \setminus \{0\}$, which is abelian under multiplication. So $\rho(ghg^{-1}h^{-1}) = \rho(g)\rho(h)\rho(g)^{-1}\rho(h)^{-1} = \rho(g)\rho(g)^{-1}\rho(h)\rho(h)^{-1} = 1$, using Theorem 0.10.3 for the inverses.

(b) Let ρ have degree 1 over $\mathbb{C}$. Transpositions are their own inverses, so $(1\ 2)(1\ 3)(1\ 2)^{-1}(1\ 3)^{-1} = (1\ 2)(1\ 3)(1\ 2)(1\ 3)$. Applying this product to each point, rightmost factor first: $1 \mapsto 3 \mapsto 3 \mapsto 1 \mapsto 2$, $2 \mapsto 2 \mapsto 1 \mapsto 3 \mapsto 3$ and $3 \mapsto 1 \mapsto 2 \mapsto 2 \mapsto 1$. So the product is $(1\ 2\ 3)$. By (a), $\rho((1\ 2\ 3)) = 1$, and then $\rho((1\ 3\ 2)) = \rho((1\ 2\ 3))^2 = 1$. Let $c = \rho((1\ 2))$. Since $(1\ 2)^2 = \mathrm{id}$, $c^2 = 1$, so $c = \pm 1$. Finally $(1\ 3) = (1\ 2\ 3)(1\ 2)$ and $(2\ 3) = (1\ 2)(1\ 2\ 3)$, so $\rho((1\ 3)) = \rho((2\ 3)) = c$ as well. Thus ρ is determined by c: for $c = 1$ it is trivial, and for $c = -1$ it agrees with sgn on every element. Both values do occur, so there are exactly two.

Exercise C2: Maschke over a field of the right characteristic.

Let $G = \mathbb{Z}/2\mathbb{Z}$ and $V = F^2$, with $\rho([1]) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.

(a) For $F = \mathbb{Q}$, find two G-invariant lines whose direct sum is V.

(b) For $F = \mathbb{F}_2$, prove that V has exactly one non-trivial G-invariant subspace, and conclude that Theorem 22.7.3 fails here. Which hypothesis is violated?

(c) For $F = \mathbb{F}_3$, decompose V into irreducible subrepresentations.

Solution.

(a) $\rho([1])$ swaps the coordinates, so $\mathbf{u} = (1,1)$ and $\mathbf{w} = (1,-1)$ satisfy $\rho([1])\mathbf{u} = \mathbf{u}$ and $\rho([1])\mathbf{w} = -\mathbf{w}$. Both lines are invariant, since $\rho([0]) = \mathbf{I}_2$ as well. The two vectors are independent, because the matrix with columns $\mathbf{u}, \mathbf{w}$ has determinant $-2 \neq 0$ in $\mathbb{Q}$; hence $\operatorname{span}(\mathbf{u}) \cap \operatorname{span}(\mathbf{w}) = \{\mathbf{0}\}$ and the sum is direct (Theorem 1.7.4). Its dimension is $2 = \dim V$, so $V = \operatorname{span}(\mathbf{u}) \oplus \operatorname{span}(\mathbf{w})$.

(b) Over $\mathbb{F}_2$ we have $-1 = 1$, so $\mathbf{w} = \mathbf{u} = (1,1)$ and the two lines coincide. A non-trivial invariant subspace is a line $\operatorname{span}((a,b))$ with $(a,b) \neq (0,0)$, and invariance requires $(b,a) = \lambda(a,b)$. Over $\mathbb{F}_2$ the only non-zero scalar is $\lambda = 1$, forcing $a = b$, so $(a,b) = (1,1)$ and the only non-trivial invariant subspace is $\operatorname{span}((1,1))$. A complement of a line in the plane V is again a line, and the only invariant line is $\operatorname{span}((1,1))$ itself, which is not a complement of itself. So this invariant subspace has no invariant complement, and V is not a direct sum of irreducibles. The violated hypothesis is on the characteristic: $\operatorname{char} \mathbb{F}_2 = 2 = |G|$.

(c) Over $\mathbb{F}_3$, $-1 = 2 \neq 1$, so $\mathbf{u} = (1,1)$ and $\mathbf{w} = (1,2)$ are again independent, with $\rho([1])\mathbf{u} = \mathbf{u}$ and $\rho([1])\mathbf{w} = 2\mathbf{w} = -\mathbf{w}$. Hence $V = \operatorname{span}(\mathbf{u}) \oplus \operatorname{span}(\mathbf{w})$, each summand of dimension 1 and so irreducible. Here $\operatorname{char} \mathbb{F}_3 = 3 \nmid 2 = |G|$, and Theorem 22.7.3 applies.

Exercise C3: The contragredient representation.

Let G be a finite group and ρ a representation of G on V over F. For $g \in G$ define $\tau(g) \coloneqq \big(\rho(g)^{-1}\big)' \in \mathcal{L}(V^*)$, where T' denotes the dual map (Definition 4.4.1).

(a) Prove that τ is a representation of G on V^*, the **contragredient** of ρ.

(b) Prove that if $U \subseteq V$ is G-invariant for ρ, then its annihilator $U^0 \subseteq V^*$ (Definition 4.2.1) is G-invariant for τ.

(c) Hence deduce that if τ is irreducible, so is ρ.

Solution.

(a) Each $\rho(g)^{-1}$ is invertible, so $\tau(g)$ is invertible by Theorem 4.4.1 (d). For multiplicativity, put $S = \rho(h)^{-1}$ and $T = \rho(g)^{-1}$. By Theorem 4.4.1 (b),

$$\begin{aligned} \tau(g)\tau(h) &= T'S' = (ST)' = \big(\rho(h)^{-1}\rho(g)^{-1}\big)' \\ &= \big((\rho(g)\rho(h))^{-1}\big)' = \big(\rho(gh)^{-1}\big)' = \tau(gh), \end{aligned}$$

where the fourth equality is Theorem 0.10.1 (3) applied in $\mathrm{GL}(V)$. So τ is a homomorphism into $\mathrm{GL}(V^*)$.

(b) Let $\varphi \in U^0$, $g \in G$ and $\mathbf{u} \in U$. By Definition 4.4.1, $\big(\tau(g)\varphi\big)(\mathbf{u}) = \varphi\big(\rho(g)^{-1}\mathbf{u}\big)$. Since $\rho(g)^{-1} = \rho(g^{-1})$ and U is G-invariant, $\rho(g)^{-1}\mathbf{u} \in U$, so the value is 0. Hence $\tau(g)\varphi$ annihilates U, that is, $\tau(g)\varphi \in U^0$.

(c) Suppose τ is irreducible. Then $V^* \neq \{\mathbf{0}\}$, so $V \neq \{\mathbf{0}\}$ by Corollary 4.1.4. Let U be a G-invariant subspace of V with $U \neq \{\mathbf{0}\}$ and $U \neq V$. By (b), U^0 is G-invariant, and by Theorem 4.2.2, $\dim U^0 = \dim V - \dim U$. From $0 < \dim U < \dim V$ we get $0 < \dim U^0 < \dim V = \dim V^*$, so U^0 is a non-trivial invariant subspace of V^*, contradicting irreducibility. Hence ρ has no such U, and ρ is irreducible.

22.8 Characters and Orthogonality

Complete reducibility (Corollary 22.7.4) promises that every complex representation of a finite group breaks into irreducible pieces, but the promise is not constructive: it says nothing about which pieces, or how many of each. This section produces a small table of numbers that answers both questions. To each representation we attach one function $G \to \mathbb{C}$, its character, and we prove that the characters of the irreducible representations are an **orthonormal basis** of a space of functions we can compute the dimension of by counting. Everything a complex representation is, up to equivalence, is then read off from one row of numbers.

Throughout, G is a **finite** group and the field is $\mathbb{C}$. The hypothesis matters twice over: $\operatorname{char}\mathbb{C} = 0$ never divides $|G|$, so Theorem 22.7.3 applies; and $\mathbb{C}$ is algebraically closed, so Schur's lemma (Theorem 22.4.1) gives that the only operators commuting with an irreducible representation are the scalars. The theory over a field whose characteristic divides $|G|$ — modular representation theory — is a different subject, and this book does not enter it.

22.8.1 Conjugacy classes

Before characters we need the sets they are constant on. The book has met them only in an exercise of Section 1 (Exercise (C1: The center of a group algebra)), so we build them here.

Definition 22.8.1 — Conjugate elements, conjugacy class

Let G be a group. Elements $g, h \in G$ are **conjugate** if $h = xgx^{-1}$ for **some** $x \in G$. The **conjugacy class** of g is

$$C(g) \coloneqq \{xgx^{-1} : x \in G\}.$$

Conjugacy is an equivalence relation (Definition 0.5.2): $g = 1g1^{-1}$ gives reflexivity; if $h = xgx^{-1}$, then $g = x^{-1}h(x^{-1})^{-1}$, which gives symmetry using Theorem 0.10.1; and if $h = xgx^{-1}$ and $k = yhy^{-1}$, then $k = (yx)g(yx)^{-1}$, which gives transitivity. Hence the conjugacy classes are the equivalence classes, and by Theorem 0.5.2 they **partition** G: every element lies in exactly one class. We write k for the number of conjugacy classes of G, a finite number since G is finite.

In an abelian group $xgx^{-1} = g$ for every x, so every class is a single element and $k = |G|$. At the other extreme, $C(1) = \{1\}$ always.

Example. (The conjugacy classes of the symmetric group on three letters)

Find the conjugacy classes of S_3.

Solution. First a rule that does the work. For $\sigma \in S_n$ and a cycle $(i_1\ i_2\ \cdots\ i_r)$,

$$\sigma\,(i_1\ i_2\ \cdots\ i_r)\,\sigma^{-1} = (\sigma(i_1)\ \sigma(i_2)\ \cdots\ \sigma(i_r)).$$

Both sides are permutations, so it is enough to check they agree at every point. At $\sigma(i_j)$: the left side applies σ^{-1} to get i_j, then the cycle to get i_{j+1} (indices read cyclically), then σ to get $\sigma(i_{j+1})$; the right side does the same in one step. At a point $\sigma(m)$ with $m \notin \{i_1, \ldots, i_r\}$: the left side gives $\sigma(m)$ back, and so does the right side, since $\sigma(m)$ is

not among the $\sigma(i_j)$ by injectivity. Every point of $\{1,\dots,n\}$ is $\sigma(m)$ for exactly one m, so the two agree.

So conjugation relabels the entries of a cycle. In S_3, conjugating $(1\ 2)$ by the six elements produces $(\sigma(1)\ \sigma(2))$, and as σ runs over S_3 the pair $\{\sigma(1),\sigma(2)\}$ runs over all three two-element subsets; so $C((1\ 2)) = \{(1\ 2),(1\ 3),(2\ 3)\}$. Conjugating $(1\ 2\ 3)$ gives $(\sigma(1)\ \sigma(2)\ \sigma(3))$, which is $(1\ 2\ 3)$ or $(1\ 3\ 2)$ according to the cyclic order; both occur, for $\sigma = \mathrm{id}$ and $\sigma = (1\ 2)$, so $C((1\ 2\ 3)) = \{(1\ 2\ 3),(1\ 3\ 2)\}$. The three classes are

$$\{\mathrm{id}\}, \qquad \{(1\ 2),(1\ 3),(2\ 3)\}, \qquad \{(1\ 2\ 3),(1\ 3\ 2)\},$$

of sizes $1,3,2$, which add to $6 = |S_3|$ as a partition must. So $k = 3$ for S_3 — the same number as the three irreducible complex representations found in Example (The irreducible complex representations of the symmetric group on three letters). That is no coincidence, and the theorem explaining it is the main result of this section.

22.8.2 The character of a representation

A representation ρ on V is a whole family of matrices, and the matrices change when the basis does. To compare representations we want something attached to ρ that does not move. Chapter 3 already supplies the candidate: the trace of an operator does not depend on the basis (Definition 3.10.2), and similar operators have equal traces.

The character of a representation records one number per group element: the trace of the operator that element acts by.

Definition 22.8.2 — Character

Let ρ be a representation of a finite group G on a finite-dimensional complex vector space V. The **character** of ρ is the function

$$\chi_\rho \colon G \to \mathbb{C}, \qquad \chi_\rho(g) \coloneqq \operatorname{tr}\rho(g).$$

Its **degree** is $\chi_\rho(1) = \dim V$. A character is **irreducible** if ρ is irreducible (Definition 22.7.4).

In words: a character is a list of $|G|$ complex numbers, one per group element, obtained by computing traces. It throws away a great deal — the whole matrix becomes one number — and the content of this section is that it throws away exactly the information we did not want.

Examples. Let G be finite.

- The trivial representation has $\chi(g) = \operatorname{tr}(\mathrm{id}_{\mathbb{C}}) = 1$ for every g. We write χ_{triv} for the constant function 1.
- The sign representation of S_n has $\chi(\sigma) = \operatorname{sgn}(\sigma)$.
- The permutation representation of S_n on $\mathbb{C}^n$ has $\chi(\sigma) = \#\{i : \sigma(i) = i\}$, the number of **fixed points**. Indeed the matrix of $\rho(\sigma)$ in the standard basis has (i,i)-entry equal to 1 exactly when $\sigma(i) = i$, and 0 otherwise.
- The regular representation on $\mathbb{C}[G]$ has $\chi_{\mathrm{reg}}(1) = |G|$ and $\chi_{\mathrm{reg}}(g) = 0$ for $g \neq 1$. The matrix of $\rho_{\mathrm{reg}}(g)$ in the basis $\{\delta_h\}$ has (h,h)-entry equal to 1 exactly when $gh = h$, that is, when $g = 1$ by cancellation (Theorem 0.10.1).

One fact about finite groups is needed first, and Chapter 0 did not record it. It costs four lines, and Section 9 will use it constantly.

Lemma 22.8.1 — Order of an Element

Let G be a finite group and $g \in G$. Then there is a least integer $m \geq 1$ with $g^m = 1$, called the **order** of g. Moreover $g^k = g^l$ if and only if m divides $k - l$, and

$$\langle g \rangle := \{g^k : k \in \mathbb{Z}\} = \{1, g, g^2, \dots, g^{m-1}\}$$

is a subgroup of G with exactly m elements.

Proof. The $|G| + 1$ elements $g^0, g^1, \dots, g^{|G|}$ cannot all be distinct, so $g^i = g^j$ for some $0 \leq i < j$. Canceling g^i (Theorem 0.10.1) gives $g^{j-i} = 1$ with $j - i \geq 1$. Hence the set of positive integers p with $g^p = 1$ is non-empty, and it has a least element m.

Suppose $g^k = g^l$, so $g^{k-l} = 1$. Divide: $k - l = qm + r$ with $0 \leq r < m$. Then

$$g^r = (g^m)^{-q}\, g^{k-l} = 1,$$

and minimality of m forces $r = 0$, that is $m \mid k - l$. Conversely $m \mid k - l$ gives $g^{k-l} = (g^m)^{(k-l)/m} = 1$, so $g^k = g^l$.

Consequently g^k depends only on k modulo m, so $\langle g \rangle = \{1, g, \dots, g^{m-1}\}$, and those m elements are distinct because $m \nmid k - l$ whenever $0 \leq l < k \leq m - 1$. Finally $1 \in \langle g \rangle$, $g^k g^l = g^{k+l} \in \langle g \rangle$ and $(g^k)^{-1} = g^{-k} \in \langle g \rangle$, so $\langle g \rangle$ is a subgroup (Definition 0.10.2).

∎

The next proposition collects the properties we use constantly. Chapter 3's trace results do all the work.

Proposition 22.8.2 — Basic properties of characters

Let ρ be a representation of a finite group G on a complex space V, with character $\chi = \chi_\rho$. Then:

(a) $\chi(1) = \dim V$;
(b) χ is a **class function**: $\chi(xgx^{-1}) = \chi(g)$ for all $g, x \in G$;
(c) equivalent representations have equal characters;
(d) if $V = U \oplus W$ with both summands G-invariant, then $\chi = \chi_{\rho|_U} + \chi_{\rho|_W}$;
(e) $\chi(g^{-1}) = \overline{\chi(g)}$ for every $g \in G$, and $|\chi(g)| \leq \chi(1)$.

Idea. Parts (a)–(d) are the four standard facts about the trace read in this setting: the trace of the identity, invariance under conjugation, invariance under similarity, and additivity over a block decomposition. Part (e) is different: it needs to know that $\rho(g)$ is diagonalizable with eigenvalues on the unit circle, which comes from g having finite order.

Proof.

(a) $\rho(1) = \mathrm{id}_V$ (Theorem 0.10.3), and $\operatorname{tr}\mathrm{id}_V = (\dim V)\cdot 1 = \dim V$ in $\mathbb{C}$ (Theorem 3.10.3).

(b) $\chi(xgx^{-1}) = \operatorname{tr}\big(\rho(x)\rho(g)\rho(x)^{-1}\big) = \operatorname{tr}\big(\rho(g)\rho(x)^{-1}\rho(x)\big) = \operatorname{tr}\rho(g) = \chi(g)$, where the second equality is $\operatorname{tr}(ST) = \operatorname{tr}(TS)$ (Theorem 3.10.3) applied with $S = \rho(x)$ and $T = \rho(g)\rho(x)^{-1}$.

(c) If $\rho'(g) = S\rho(g)S^{-1}$ for an isomorphism S (Definition 22.7.3), the same computation as in (b) gives $\operatorname{tr}\rho'(g) = \operatorname{tr}\rho(g)$.

(d) Choose a basis of V formed by a basis of U followed by a basis of W. Since both are invariant, the matrix of $\rho(g)$ in this basis is block diagonal, with the matrices of $\rho(g)|_U$ and $\rho(g)|_W$ on the diagonal. The diagonal entries of the big matrix are those of the two blocks, so the traces add (Definition 3.10.2).

(e) We may assume $V \neq \{\mathbf{0}\}$, since otherwise χ is the zero function and both claims are clear.

Finite order. By Lemma 22.8.1 there is an integer $d \geq 1$ with $g^d = 1$, namely the order of g.

Diagonalizability. Then $\rho(g)^d = \rho(g^d) = \mathrm{id}_V$, so the polynomial $x^d - 1$ annihilates $\rho(g)$. Over $\mathbb{C}$ it equals $\prod_{m=0}^{d-1}(x - \zeta^m)$ with $\zeta = e^{2\pi i/d}$, a product of **distinct** linear factors (Example (Roots of Unity)). By Theorem 8.8.2, (c) $\Rightarrow$ (a), $\rho(g)$ is diagonalizable, and every eigenvalue λ satisfies $\lambda^d = 1$, hence $|\lambda| = 1$.

Conclusion. Let $\lambda_1, \dots, \lambda_n$ be the diagonal entries in an eigenbasis, $n = \dim V$. Then $\chi(g) = \sum_j \lambda_j$. In the same basis $\rho(g)^{-1} = \rho(g^{-1})$ is diagonal with entries λ_j^{-1}, and $|\lambda_j| = 1$ gives $\lambda_j^{-1} = \overline{\lambda_j}$. Hence $\chi(g^{-1}) = \sum_j \overline{\lambda_j} = \overline{\chi(g)}$. Finally $|\chi(g)| \leq \sum_j |\lambda_j| = n = \chi(1)$ by the triangle inequality for complex numbers (Theorem 0.6.4), applied repeatedly. This proves the proposition.

■

Warning. **A character is not a homomorphism.** For the standard representation of S_3 (Example (The irreducible complex representations of the symmetric group on three letters)), $\chi((1\ 2)) = 0$ and $\chi((1\ 3)) = 0$, while $(1\ 2)(1\ 3) = (1\ 3\ 2)$ has $\chi((1\ 3\ 2)) = -1 \neq 0 \cdot 0$. Only characters of **degree** 1 are homomorphisms, because then $\chi(g)$ is the whole operator. Nor need the values of a character be real: for $\mathbb{Z}/4\mathbb{Z}$ they include $\pm i$.

Quick check. A representation of G has character χ with $\chi(1) = 3$ and $\chi(g) = 4$ for some g. What is wrong?

Solution. Nothing can have such a character: by Proposition 22.8.2 (e), $|\chi(g)| \leq \chi(1) = 3$ for every g, and $4 > 3$. The bound says a character is largest, in absolute value, at the identity.

22.8.3 Class functions and their inner product

Part (b) of Proposition 22.8.2 says every character lives in one particular space of functions, and that space is small enough to be a useful home.

Definition 22.8.3 — Class function

Let G be a finite group. A function $f\colon G \to \mathbb{C}$ is a **class function** if $f(xgx^{-1}) = f(g)$ for all $g, x \in G$; equivalently, if f is constant on each conjugacy class. The set of class functions is written $\mathrm{Cl}(G)$.

The functions $G \to \mathbb{C}$ form a complex vector space under the pointwise operations (Example (The Standard Vector Spaces) (d)). The zero function is a class function, and sums and scalar multiples of class functions are class functions, so $\mathrm{Cl}(G)$ is a subspace of it (Theorem 1.2.1). Its dimension is exactly what we want to count.

Non-example by minimal change. On S_3, the function f that is 1 at $(1\ 2)$ and 0 elsewhere is **not** a class function: $(1\ 3) = \sigma(1\ 2)\sigma^{-1}$ for $\sigma = (2\ 3)$, so f would have to take the same value at $(1\ 3)$, and it takes 0 there. Changing f to be 1 on **all three** transpositions repairs it; that is the indicator function of a whole class, and those are the building blocks below.

Proposition 22.8.3 — The class functions have dimension the number of classes

Let G be a finite group with conjugacy classes $C_1, \dots, C_k$. For each j let $1_{C_j}\colon G \to \mathbb{C}$ be the function that is 1 on C_j and 0 elsewhere. Then $(1_{C_1}, \dots, 1_{C_k})$ is a basis of $\mathrm{Cl}(G)$, and $\dim \mathrm{Cl}(G) = k$.

Proof. Each 1_{C_j} is constant on every class — it is 1 on C_j and 0 on the others — so it lies in $\mathrm{Cl}(G)$.

Spanning. Let $f \in \mathrm{Cl}(G)$ and pick $g_j \in C_j$ for each j. Every $g \in G$ lies in exactly one class C_j (the classes partition G), and then $f(g) = f(g_j)$ while $\sum_l f(g_l) 1_{C_l}(g) = f(g_j)$. So $f = \sum_j f(g_j) 1_{C_j}$.

Independence. Suppose $\sum_j c_j 1_{C_j} = 0$. Evaluating at $g_j \in C_j$ gives $c_j = 0$, since every other 1_{C_l} vanishes there. Hence the list is a basis and $\dim \mathrm{Cl}(G) = k$.

■

Now the pairing. It is the standard inner product of $\mathbb{C}^{|G|}$, with the coordinates indexed by G and normalized by $|G|$ so that the trivial character has length 1.

Definition 22.8.4 — The inner product of class functions

For functions $f, f'\colon G \to \mathbb{C}$ on a finite group G, set

$$\langle f, f' \rangle := \frac{1}{|G|} \sum_{g \in G} f(g)\, \overline{f'(g)}.$$

This satisfies (IP1)–(IP3) of Definition 10.1.1 on the space of all functions $G \to \mathbb{C}$, hence on the subspace $\mathrm{Cl}(G)$: linearity in the first slot and conjugate symmetry are immediate from the formula, and $\langle f, f \rangle = \frac{1}{|G|} \sum_g |f(g)|^2 > 0$ whenever $f \neq 0$, since some term is positive and none is negative. So $\mathrm{Cl}(G)$ is a complex inner product space of dimension k, and all of Chapter 10 is

available in it.

When f and f' are class functions the sum can be shortened to one term per class: with $c_j = |C_j|$ and $g_j \in C_j$,

$$\langle f, f' \rangle = \frac{1}{|G|} \sum_{j=1}^{k} c_j \, f(g_j) \, \overline{f'(g_j)}. \tag{22.8.1}$$

That is the formula used for hand computation, and it is the only place the class sizes enter.

22.8.4 Two averaging lemmas

Both proofs of orthogonality run through the same device as Maschke's theorem: average over G, and the average is G-invariant. Here we also need its trace.

Lemma 22.8.4 — The average of a representation is the projection onto the fixed space

Let ρ be a representation of a finite group G on a complex space V, and set

$$V^G := \{\mathbf{v} \in V : \rho(g)\mathbf{v} = \mathbf{v} \text{ for all } g \in G\}, \qquad P := \frac{1}{|G|} \sum_{g \in G} \rho(g).$$

Then V^G is a subspace, P is a projection with $\operatorname{im} P = V^G$, and

$$\frac{1}{|G|} \sum_{g \in G} \chi_\rho(g) = \dim V^G.$$

Proof. $V^G = \bigcap_{g \in G} \ker(\rho(g) - \mathrm{id}_V)$ is an intersection of subspaces, hence a subspace (Theorem 1.2.2).

Fix $h \in G$. Then $\rho(h)P = \frac{1}{|G|} \sum_g \rho(hg) = P$, because $g \mapsto hg$ is a bijection of G (Theorem 0.10.1) and so only reorders the terms. Hence $\rho(h)(P\mathbf{v}) = P\mathbf{v}$ for every $\mathbf{v}$, giving $\operatorname{im} P \subseteq V^G$. Conversely, if $\mathbf{v} \in V^G$ then $P\mathbf{v} = \frac{1}{|G|} \sum_g \mathbf{v} = \mathbf{v}$. So P is the identity on V^G; combined with $\operatorname{im} P \subseteq V^G$ this gives $P^2 = P$ and $\operatorname{im} P = V^G$.

Thus P is a projection (Definition 3.10.1) of rank $\dim V^G$, and $\operatorname{tr} P = \dim V^G$ by Theorem 3.10.4, the field being $\mathbb{C}$. On the other hand the trace is linear (Theorem 3.10.3), so $\operatorname{tr} P = \frac{1}{|G|} \sum_g \operatorname{tr} \rho(g) = \frac{1}{|G|} \sum_g \chi_\rho(g)$. This proves the lemma.

■

Lemma 22.8.5 — The trace of a two-sided multiplication

Let V and W be finite-dimensional vector spaces over a field F, let $A \in \mathcal{L}(V)$ and $B \in \mathcal{L}(W)$, and let

$$\Phi \colon \mathcal{L}(V, W) \to \mathcal{L}(V, W), \qquad \Phi(f) = B \circ f \circ A.$$

Then Φ is linear and $\operatorname{tr}\Phi = (\operatorname{tr} A)(\operatorname{tr} B)$.

Idea. Write everything in coordinates. In the basis of $\mathcal{L}(V,W)$ given by the matrix units $\mathbf{E}_{ij}$, the map $\mathbf{X}\mapsto \mathbf{BXA}$ sends $\mathbf{E}_{ij}$ to a matrix whose (i,j)-entry is $b_{ii}a_{jj}$; adding those diagonal coefficients factorizes as a product of two sums.

Proof. Linearity of Φ is immediate from bilinearity of composition. Fix bases of V and W and identify $\mathcal{L}(V,W)$ with $M_{m\times n}(F)$, where $n=\dim V$ and $m=\dim W$ (Theorem 3.6.4); let $\mathbf{A}=(a_{jl})\in M_n(F)$ and $\mathbf{B}=(b_{ki})\in M_m(F)$ be the matrices of A and B. Under the identification Φ becomes $\mathbf{X}\mapsto \mathbf{BXA}$.

Let $\mathbf{E}_{ij}\in M_{m\times n}(F)$ be the matrix unit with a 1 in position (i,j) and zeros elsewhere — the rectangular version of the matrix units of Lemma 22.2.1; these mn matrices form a basis. By Definition 0.9.9,

$$(\mathbf{B}\,\mathbf{E}_{ij}\,\mathbf{A})_{kl}=\sum_{p,q} b_{kp}(\mathbf{E}_{ij})_{pq}a_{ql}=b_{ki}\,a_{jl}.$$

In the basis $(\mathbf{E}_{ij})$, the coefficient of $\mathbf{E}_{ij}$ in $\Phi(\mathbf{E}_{ij})$ is the (i,j)-entry of $\mathbf{B}\mathbf{E}_{ij}\mathbf{A}$, namely $b_{ii}a_{jj}$. These coefficients are the diagonal entries of the matrix of Φ, so by Definition 3.10.2,

$$\operatorname{tr}\Phi=\sum_{i=1}^{m}\sum_{j=1}^{n} b_{ii}a_{jj}=\Big(\sum_i b_{ii}\Big)\Big(\sum_j a_{jj}\Big)=(\operatorname{tr}\mathbf{B})(\operatorname{tr}\mathbf{A}),$$

and $\operatorname{tr}\mathbf{A}=\operatorname{tr}A$, $\operatorname{tr}\mathbf{B}=\operatorname{tr}B$ by Definition 3.10.2. This proves the lemma. ∎

Now put the two together. Given representations ρ on V and σ on W, make G act on the space $\mathcal{L}(V,W)$ of linear maps by

$$\pi(g)f:=\sigma(g)\circ f\circ\rho(g)^{-1}.$$

Proposition 22.8.6 — The representation on the space of linear maps

Let ρ,σ be representations of a finite group G on complex spaces V,W. Then π above is a representation of G on $\mathcal{L}(V,W)$, its character is $\chi_\pi(g)=\chi_\sigma(g)\overline{\chi_\rho(g)}$, and its fixed space is the space

$$\mathcal{L}_G(V,W):=\{f\in\mathcal{L}(V,W):f\rho(g)=\sigma(g)f\ \text{for all } g\in G\}$$

of maps intertwining ρ and σ (Definition 22.7.3); for $W=V$ and $\sigma=\rho$ this is the commutant $\operatorname{End}_{\mathbb{C}[G]}(V)$ of Definition 22.4.1. Consequently

$$\frac{1}{|G|}\sum_{g\in G}\chi_\sigma(g)\overline{\chi_\rho(g)}=\dim\mathcal{L}_G(V,W). \tag{22.8.2}$$

Proof. A representation. Each $\pi(g)$ is linear in f, and $\pi(g)\pi(h)f=\sigma(g)\sigma(h)f\rho(h)^{-1}\rho(g)^{-1}=\sigma(gh)f\rho(gh)^{-1}=\pi(gh)f$, using the homomorphism property of ρ and σ and Theo-

rem 0.10.1 for the inverse of a product. Taking $h = g^{-1}$ shows $\pi(g)$ is invertible with inverse $\pi(g^{-1})$.

Its character. Apply Lemma 22.8.5 with $A = \rho(g)^{-1}$ and $B = \sigma(g)$:

$$\begin{aligned}\chi_\pi(g) &= \operatorname{tr}\pi(g) = \operatorname{tr}\big(\rho(g)^{-1}\big)\,\operatorname{tr}\big(\sigma(g)\big)\\ &= \chi_\rho(g^{-1})\chi_\sigma(g) = \overline{\chi_\rho(g)}\,\chi_\sigma(g),\end{aligned}$$

the last step by Proposition 22.8.2 (e).

Its fixed space. $\pi(g)f = f$ means $\sigma(g)f\rho(g)^{-1} = f$, and composing with $\rho(g)$ on the right turns this into $\sigma(g)f = f\rho(g)$. So the fixed space is exactly $\mathcal{L}_G(V,W)$.

The count. Apply Lemma 22.8.4 to π and substitute the character just computed. This proves the proposition.

■

22.8.5 Orthogonality of the irreducible characters

Everything is now in place. Schur's lemma converts the right-hand side of Eq. 22.8.2 into a 0 or a 1.

Theorem 22.8.7 — Orthogonality of Irreducible Characters

Let G be a finite group and let ρ on V and σ on W be **irreducible** complex representations of G. Then

$$\langle \chi_\sigma, \chi_\rho\rangle = \begin{cases} 1, & \text{if } \rho \cong \sigma,\\ 0, & \text{if } \rho \ncong \sigma.\end{cases}$$

In particular the characters of pairwise inequivalent irreducible complex representations form an orthonormal list in $\mathrm{Cl}(G)$.

Idea. By Eq. 22.8.2, $\langle \chi_\sigma, \chi_\rho\rangle$ counts the dimension of the space of intertwining maps $V \to W$. Schur's lemma says that space is $\{0\}$ when the two are inequivalent, because a non-zero intertwiner would be an isomorphism. When they are equivalent, fix one isomorphism S_0; every other intertwiner differs from it by an intertwiner of V with itself, which over $\mathbb{C}$ is a scalar. So the space is the line $\mathbb{C}S_0$.

Proof. By Eq. 22.8.2, $\langle \chi_\sigma, \chi_\rho\rangle = \dim \mathcal{L}_G(V,W)$, which is a non-negative integer. It remains to compute that dimension.

Case 1: $\rho \ncong \sigma$. By Theorem 22.7.1, V and W are irreducible $\mathbb{C}[G]$-spaces; and since the condition $f\rho(g) = \sigma(g)f$ for all $g \in G$ extends by linearity to all of $\mathbb{C}[G]$, the members of $\mathcal{L}_G(V,W)$ are exactly the $\mathbb{C}[G]$-maps $V \to W$ (Definition 22.4.1). Let $f \in \mathcal{L}_G(V,W)$ be non-zero. By Theorem 22.4.1 (a) it is an isomorphism, making ρ and σ equivalent (Definition 22.7.3) — a contradiction. Hence $\mathcal{L}_G(V,W) = \{0\}$ and the inner product is 0.

Case 2: $\rho \cong \sigma$. Fix an isomorphism $S_0 \in \mathcal{L}_G(V,W)$, so $S_0\rho(g) = \sigma(g)S_0$ for all g. Applying S_0^{-1} on both sides gives $\rho(g)S_0^{-1} = S_0^{-1}\sigma(g)$, so S_0^{-1} intertwines σ with ρ. Let

$f \in \mathcal{L}_G(V,W)$ and set $u := S_0^{-1} f \in \mathcal{L}(V)$. Then for every g,

$$u\rho(g) = S_0^{-1} f \rho(g) = S_0^{-1}\sigma(g) f = \rho(g) S_0^{-1} f = \rho(g) u,$$

so u commutes with every $\rho(g)$. Since ρ is irreducible and the field is algebraically closed, Corollary 22.4.3 gives $u = \lambda \,\mathrm{id}_V$ for some $\lambda \in \mathbb{C}$, and hence $f = S_0 u = \lambda S_0$. Therefore $\mathcal{L}_G(V,W) = \mathbb{C} S_0$, which has dimension 1 because $S_0 \neq 0$.

The last sentence of the statement follows: distinct members of a list of pairwise inequivalent irreducibles pair to 0, and each pairs with itself to 1. This proves the theorem.

■

Two consequences come for free, and both are used in every computation below.

Corollary 22.8.8 — Irreducibility criterion

Let ρ be a complex representation of a finite group G on $V \neq \{\mathbf{0}\}$, with character χ. Write $V = V_1 \oplus \cdots \oplus V_r$ with each V_i irreducible (Corollary 22.7.4), and let $\chi_1, \dots, \chi_s$ be the distinct characters occurring among the $\chi_{\rho|_{V_i}}$, with multiplicities $m_1, \dots, m_s \geq 1$. Then

$$\chi = \sum_{i=1}^{s} m_i \chi_i, \qquad m_i = \langle \chi, \chi_i \rangle, \qquad \langle \chi, \chi \rangle = \sum_{i=1}^{s} m_i^2.$$

In particular $\langle \chi, \chi \rangle = 1$ if and only if ρ is irreducible, and two complex representations of G with the same character are equivalent.

Proof. Repeated use of Proposition 22.8.2 (d) gives $\chi = \sum_{i=1}^{r} \chi_{\rho|_{V_i}}$, and grouping equal terms gives $\chi = \sum_i m_i \chi_i$. Distinct characters come from inequivalent representations, since equivalent ones have equal characters (Proposition 22.8.2 (c)); so by Theorem 22.8.7 the χ_i are orthonormal, and $\langle \chi, \chi_i \rangle = m_i$ and, expanding the pairing in the first slot and then in the second, $\langle \chi, \chi \rangle = \sum_i m_i^2$.

If ρ is irreducible then $s = 1$ and $m_1 = 1$, so $\langle \chi, \chi \rangle = 1$. Conversely, a sum of squares of positive integers equals 1 only when there is a single term equal to 1; then $r = 1$ and $V = V_1$ is irreducible.

For the last claim, suppose ρ and ρ' have the same character. Every irreducible character ψ of G then has $\langle \chi_\rho, \psi \rangle = \langle \chi_{\rho'}, \psi \rangle$, so each irreducible occurs with the same multiplicity in both decompositions. So the two decompositions into irreducibles use the same irreducibles with the same multiplicities, and the summands can be matched in pairs with equal characters. Two irreducible summands with equal characters are equivalent: were they inequivalent, Theorem 22.8.7 would make their characters orthogonal, hence unequal, since an irreducible character pairs with itself to 1 and not to 0. The direct sum of those equivalences is an isomorphism $V \to V'$ intertwining ρ and ρ'. This proves the corollary.

■

Example. (Checking the standard representation by its character)

Use Corollary 22.8.8 to confirm that the two-dimensional representation of S_3 built in Example (The irreducible complex representations of the symmetric group on three letters) is irreducible, and decompose the permutation representation of S_3 on $\mathbb{C}^3$.

Solution. From Example (The irreducible complex representations of the symmetric group on three letters) the matrices give $\chi_{\text{std}}(\text{id}) = 2$, $\chi_{\text{std}}((1\ 2)) = -1 + 1 = 0$ and $\chi_{\text{std}}((1\ 2\ 3)) = 0 + (-1) = -1$; by Proposition 22.8.2 (b) these three values determine χ_{std} on all of S_3, the classes being those of Example (The conjugacy classes of the symmetric group on three letters). Using Eq. 22.8.1 with class sizes $1, 3, 2$,

$$\langle \chi_{\text{std}}, \chi_{\text{std}} \rangle = \tfrac{1}{6}\big(1 \cdot 2^2 + 3 \cdot 0^2 + 2 \cdot (-1)^2\big) = \tfrac{4+0+2}{6} = 1,$$

so the representation is irreducible.

For the permutation representation, χ_{perm} counts fixed points: 3 at id, 1 at a transposition, 0 at a 3-cycle. Then

$$\begin{aligned} \langle \chi_{\text{perm}}, \chi_{\text{triv}} \rangle &= \tfrac{1}{6}(1 \cdot 3 + 3 \cdot 1 + 2 \cdot 0) = 1, \\ \langle \chi_{\text{perm}}, \chi_{\text{sgn}} \rangle &= \tfrac{1}{6}(1 \cdot 3 + 3 \cdot 1 \cdot (-1) + 2 \cdot 0) = 0, \\ \langle \chi_{\text{perm}}, \chi_{\text{std}} \rangle &= \tfrac{1}{6}(1 \cdot 3 \cdot 2 + 0 + 0) = 1. \end{aligned}$$

So $\chi_{\text{perm}} = \chi_{\text{triv}} + \chi_{\text{std}}$, and by Corollary 22.8.8 the permutation representation is the direct sum of the trivial and the standard one. That matches the splitting $\mathbb{C}^3 = \text{span}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3) \oplus W$ found by hand in Example (The irreducible complex representations of the symmetric group on three letters), and it was found here without looking at a single vector.

22.8.6 The characters span the class functions

Orthonormality already bounds the number of irreducible representations: an orthonormal list in $\text{Cl}(G)$ is independent (Theorem 10.1.4), so there are at most k of them up to equivalence. The next theorem shows there are exactly k. It is the deepest statement of the section, and its proof is the third and last averaging argument: this time we average the group elements themselves, weighted by a class function.

Theorem 22.8.9 — The Irreducible Characters Are a Basis of the Class Functions

Let G be a finite group with k conjugacy classes. Then G has exactly k irreducible complex representations up to equivalence, and their characters $\chi_1, \dots, \chi_k$ form an orthonormal **basis** of $\text{Cl}(G)$.

Idea. Suppose a class function f is orthogonal to every irreducible character; we must show $f = 0$. Build from f the operator $T_f = \sum_g \overline{f(g)}\rho(g)$ on any representation ρ. ① Because f is a class function, T_f commutes with every $\rho(h)$ — conjugating by $\rho(h)$ permutes the terms and leaves the coefficients alone. ② So on an irreducible ρ it is a scalar, and its trace, which is $|G|\langle \chi_\rho, f \rangle = 0$, forces that scalar to be 0. ③ Complete reducibility (Corollary 22.7.4) spreads this to every representation. ④ Apply it to the regular representation and evaluate at δ_1: the result is $\sum_g \overline{f(g)}\delta_g = 0$, and the δ_g are a

basis.

Proof. Orthonormal lists are independent (Theorem 10.1.4) and $\dim \mathrm{Cl}(G) = k$ (Proposition 22.8.3), so by Theorem 22.8.7 any list of pairwise inequivalent irreducible representations has at most k members. Choose such a list $\rho_1, \dots, \rho_s$ with s as large as possible; by maximality every irreducible complex representation of G is equivalent to some ρ_i. Write $\chi_i = \chi_{\rho_i}$, and let $U = \operatorname{span}(\chi_1, \dots, \chi_s) \subseteq \mathrm{Cl}(G)$, using Proposition 22.8.2 (b).

Let $f \in U^{\perp}$, the orthogonal complement of U in $\mathrm{Cl}(G)$ (Definition 10.3.1), so f is a class function with $\langle f, \chi_i \rangle = 0$, hence also $\langle \chi_i, f \rangle = \overline{\langle f, \chi_i \rangle} = 0$, for every i. For **any** representation ρ of G on V, define

$$T_f^{\rho} := \sum_{g \in G} \overline{f(g)}\, \rho(g) \in \mathcal{L}(V).$$

Claim. **Claim 1.** T_f^{ρ} commutes with $\rho(h)$ for every $h \in G$.

Proof. Fix h. Then

$$\rho(h)\, T_f^{\rho}\, \rho(h)^{-1} = \sum_{g \in G} \overline{f(g)}\, \rho(hgh^{-1}).$$

The map $g \mapsto hgh^{-1}$ is a bijection $G \to G$, with inverse $g \mapsto h^{-1}gh$. Substituting $g' = hgh^{-1}$, so that $g = h^{-1}g'h$, the sum becomes $\sum_{g'} \overline{f(h^{-1}g'h)}\rho(g')$. Since f is a class function, $f(h^{-1}g'h) = f(g')$, so the sum is T_f^{ρ}. Multiplying on the right by $\rho(h)$ gives the claim.

■

Claim. **Claim 2.** If ρ is irreducible, then $T_f^{\rho} = 0$.

Proof. By Claim 1 and Corollary 22.4.3, over the algebraically closed field $\mathbb{C}$ we get $T_f^{\rho} = \lambda \, \mathrm{id}_V$ for some $\lambda \in \mathbb{C}$. Taking traces and using linearity of the trace (Theorem 3.10.3),

$$\lambda \dim V = \operatorname{tr} T_f^{\rho} = \sum_{g} \overline{f(g)}\, \chi_{\rho}(g) = |G|\, \langle \chi_{\rho}, f \rangle.$$

Now ρ is equivalent to some ρ_i, so $\chi_{\rho} = \chi_i$ by Proposition 22.8.2 (c), and $\langle \chi_i, f \rangle = 0$. Since $\dim V \geq 1$, $\lambda = 0$.

■

Claim. **Claim 3.** $T_f^\rho = 0$ for **every** representation ρ.

Proof. We may assume $V \neq \{\mathbf{0}\}$. By Corollary 22.7.4, $V = V_1 \oplus \cdots \oplus V_r$ with each V_j invariant and $\rho|_{V_j}$ irreducible. Each $\rho(g)$ maps V_j into V_j, hence so does T_f^ρ, and its restriction to V_j is $\sum_g \overline{f(g)}\,\rho|_{V_j}(g) = T_f^{\rho|_{V_j}}$, which is 0 by Claim 2. So T_f^ρ vanishes on each V_j, hence on their sum V. ∎

Now apply Claim 3 to the regular representation ρ_{reg} on $\mathbb{C}[G]$, where $\rho_{\mathrm{reg}}(g)\delta_h = \delta_{gh}$. Evaluating at the basis vector δ_1,

$$0 = T_f^{\rho_{\mathrm{reg}}}\delta_1 = \sum_{g\in G} \overline{f(g)}\,\delta_g.$$

The δ_g are a basis of $\mathbb{C}[G]$, so every coefficient vanishes: $\overline{f(g)} = 0$, that is $f(g) = 0$, for all g. Hence $U^\perp = \{0\}$.

By Theorem 10.3.2, $\mathrm{Cl}(G) = U \oplus U^\perp = U$. So $(\chi_1, \ldots, \chi_s)$ is an orthonormal spanning list, hence a basis, and $s = \dim \mathrm{Cl}(G) = k$ by Proposition 22.8.3. Finally, inequivalent irreducibles have different characters, since orthonormality gives $\langle \chi_i, \chi_j\rangle = 0 \neq 1 = \langle \chi_i, \chi_i\rangle$ for $i \neq j$; so the k characters correspond to the k equivalence classes of irreducible representations. This proves the theorem. ∎

Corollary 22.8.10 — The sum of the squares of the degrees

Let G be a finite group and let $\rho_1, \ldots, \rho_k$ on $V_1, \ldots, V_k$ be a complete list of pairwise inequivalent irreducible complex representations of G, one for each of the k conjugacy classes (Theorem 22.8.9). Then each ρ_i occurs in the regular representation with multiplicity exactly $\dim V_i$, and

$$|G| = \sum_{i=1}^{k} (\dim V_i)^2.$$

Proof. The regular character is $\chi_{\mathrm{reg}}(1) = |G|$ and $\chi_{\mathrm{reg}}(g) = 0$ for $g \neq 1$, as computed after Definition 22.8.2. Hence

$$\langle \chi_{\mathrm{reg}}, \chi_i\rangle = \frac{1}{|G|}\sum_g \chi_{\mathrm{reg}}(g)\overline{\chi_i(g)} = \frac{1}{|G|}\,|G|\,\overline{\chi_i(1)} = \dim V_i,$$

the value $\chi_i(1) = \dim V_i$ being a real number (Proposition 22.8.2 (a)). By Corollary 22.8.8 this inner product is the multiplicity of ρ_i in ρ_{reg}, so $\chi_{\mathrm{reg}} = \sum_i (\dim V_i)\chi_i$. Evaluating at $g = 1$ gives $|G| = \sum_i (\dim V_i)\chi_i(1) = \sum_i (\dim V_i)^2$. ∎

This is Corollary 22.6.2, the count $\dim A = \sum n_i^2$ of the structure theorem, applied to $A = \mathbb{C}[G]$: the two proofs are different and the answer is the same.

Corollary 22.8.11 — Orthogonality of the columns

Let G be a finite group with conjugacy classes $C_1, \dots, C_k$, representatives $g_j \in C_j$ and sizes $c_j = |C_j|$, and irreducible characters $\chi_1, \dots, \chi_k$. Then for all j, l,

$$\sum_{i=1}^{k} \chi_i(g_j)\,\overline{\chi_i(g_l)} = \begin{cases} |G|/c_j, & j = l, \\ 0, & j \neq l. \end{cases}$$

Idea. Theorem 22.8.9 makes the table of character values a **square** array. Rescale it so that orthonormality of the rows says the matrix is unitary; then its columns are orthonormal too, because a one-sided inverse of a square matrix is two-sided.

Proof. Let $\mathbf{U} \in M_k(\mathbb{C})$ have entries $u_{ij} = \sqrt{c_j/|G|}\;\chi_i(g_j)$; the square root is a positive real. By Eq. 22.8.1 and Theorem 22.8.7,

$$(\mathbf{U}\mathbf{U}^{*})_{ii'} = \sum_{j=1}^{k} u_{ij}\overline{u_{i'j}} = \frac{1}{|G|}\sum_{j=1}^{k} c_j\,\chi_i(g_j)\overline{\chi_{i'}(g_j)} = \langle \chi_i, \chi_{i'} \rangle,$$

which is 1 for $i = i'$ and 0 otherwise. Hence $\mathbf{U}\mathbf{U}^{*} = \mathbf{I}_k$. By Theorem 2.4.5, $\mathbf{U}^{*}\mathbf{U} = \mathbf{I}_k$ as well, so for all j, l

$$\sum_{i=1}^{k} \overline{u_{ij}}\,u_{il} = \frac{\sqrt{c_j c_l}}{|G|}\sum_{i=1}^{k} \overline{\chi_i(g_j)}\,\chi_i(g_l)$$

equals 1 when $j = l$ and 0 otherwise. For $j = l$ this gives $\sum_i |\chi_i(g_j)|^2 = |G|/c_j$, and for $j \neq l$ it gives $\sum_i \overline{\chi_i(g_j)}\chi_i(g_l) = 0$. Conjugating the second identity, which is a sum of complex numbers, gives the stated form. This proves the corollary.

■

22.8.7 Two character tables

The **character table** of G is the $k \times k$ array whose (i, j)-entry is $\chi_i(g_j)$: one row per irreducible character, one column per conjugacy class. By Theorem 22.8.9 it is square, by Theorem 22.8.7 its rows are orthonormal, and by Corollary 22.8.11 its columns are orthogonal.

Example. (The character table of the symmetric group on three letters)

Write down the character table of S_3 and verify every orthogonality relation.

Solution. By Example (The conjugacy classes of the symmetric group on three letters) there are $k = 3$ classes, with representatives id, (1 2), (1 2 3) and sizes $1, 3, 2$. So there are three irreducible complex representations (Theorem 22.8.9), and Example (The irreducible complex representations of the symmetric group on three letters) produced three: the trivial, the sign and the standard one. Their characters, from the definitions and the traces computed in Example (Checking the standard representation by its character), are:

	id	(1 2)	(1 2 3)
class size	1	3	2
χ_{triv}	1	1	1
χ_{sgn}	1	-1	1
χ_{std}	2	0	-1

Degrees. $1^2 + 1^2 + 2^2 = 6 = |S_3|$, as Corollary 22.8.10 requires.

Row orthogonality, from Eq. 22.8.1 with weights $1, 3, 2$ and divisor 6. All values are real, so conjugation does nothing:

$$\begin{aligned}
\langle \chi_{\text{triv}}, \chi_{\text{triv}} \rangle &= \tfrac{1}{6}(1+3+2) = 1, \\
\langle \chi_{\text{sgn}}, \chi_{\text{sgn}} \rangle &= \tfrac{1}{6}(1+3+2) = 1, \\
\langle \chi_{\text{std}}, \chi_{\text{std}} \rangle &= \tfrac{1}{6}(4+0+2) = 1, \\
\langle \chi_{\text{triv}}, \chi_{\text{sgn}} \rangle &= \tfrac{1}{6}(1-3+2) = 0, \\
\langle \chi_{\text{triv}}, \chi_{\text{std}} \rangle &= \tfrac{1}{6}(2+0-2) = 0, \\
\langle \chi_{\text{sgn}}, \chi_{\text{std}} \rangle &= \tfrac{1}{6}(2+0-2) = 0.
\end{aligned}$$

Column orthogonality, from Corollary 22.8.11, with no weights this time:

$$\begin{aligned}
\text{column id}: &\quad 1+1+4 = 6 = 6/1, \\
\text{column } (1\ 2): &\quad 1+1+0 = 2 = 6/3, \\
\text{column } (1\ 2\ 3): &\quad 1+1+1 = 3 = 6/2, \\
\text{id against } (1\ 2): &\quad 1\cdot 1 + 1\cdot(-1) + 2\cdot 0 = 0, \\
\text{id against } (1\ 2\ 3): &\quad 1+1-2 = 0, \\
(1\ 2) \text{ against } (1\ 2\ 3): &\quad 1-1+0 = 0.
\end{aligned}$$

Every relation holds.

Example. (The character table of a cyclic group of order four)

Write down the character table of $\mathbb{Z}/4\mathbb{Z}$ and verify the orthogonality relations.

Solution. The group is abelian, so every conjugacy class is a single element and $k = 4$. By Theorem 22.8.9 there are four irreducible complex representations, and Example (The irreducible complex representations of a cyclic group) produced four, all of degree 1: $\chi_m([j]) = i^{jm}$, using $\omega = e^{2\pi i/4} = i$. Their degrees satisfy $1^2 + 1^2 + 1^2 + 1^2 = 4 = |G|$.

	[0]	[1]	[2]	[3]
χ_0	1	1	1	1
χ_1	1	i	-1	$-i$
χ_2	1	-1	1	-1
χ_3	1	$-i$	-1	i

Row orthogonality. For characters of degree 1, $\overline{\chi_l([j])} = i^{-jl}$, so

$$\langle \chi_m, \chi_l \rangle = \frac{1}{4} \sum_{j=0}^{3} i^{j(m-l)}.$$

If $m = l$ every term is 1 and the sum is $4/4 = 1$. If $m \neq l$, put $d = m - l$, so $i^d \neq 1$ and $(i^d)^4 = 1$; then $(i^d - 1)\sum_{j=0}^{3}(i^d)^j = (i^d)^4 - 1 = 0$, and dividing by $i^d - 1 \neq 0$ gives $\sum_j i^{jd} = 0$. For instance $\langle \chi_1, \chi_0 \rangle = \frac{1}{4}(1+i-1-i) = 0$ and $\langle \chi_3, \chi_1 \rangle = \frac{1}{4}(1-1+1-1) = 0$.

Column orthogonality. Every class has size 1, so Corollary 22.8.11 predicts 4 down the diagonal and 0 off it. The same geometric sum settles every one of them: column $[j]$ against column $[l]$ gives $\sum_{m=0}^{3} \chi_m([j])\overline{\chi_m([l])} = \sum_{m=0}^{3} i^{m(j-l)}$, which is 4 when $j = l$, and is 0 otherwise by the computation just made, read with $d = j - l$. Three of them written out. Column [1] against itself: $1+|i|^2+1+|-i|^2 = 4$. Column [0] against [2]: the entries of column [0] are $1, 1, 1, 1$ and those of column [2] are $1, -1, 1, -1$, so the sum is $1\cdot 1+1\cdot(-1)+1\cdot 1+1\cdot(-1) = 0$. Column [1] against [3]: $1+i\cdot\overline{(-i)}+(-1)\overline{(-1)}+(-i)\overline{i} = 1 + i\cdot i + 1 + (-i)(-i) = 1 - 1 + 1 - 1 = 0$.

Read as a matrix, the table is $(i^{jm})_{m,j}$, which up to the factor $1/2$ is the 4×4 Fourier matrix of Example (The Fourier matrix of size four). That is not a coincidence, and Section 09 explains it.

Warning. **The character table does not determine the group.** Two non-isomorphic groups can have identical character tables. The standard witness is a pair of groups of order 8: the eight symmetries of a square (four rotations and four reflections), and the group $\{\pm\mathbf{I}_2, \pm\mathbf{i}, \pm\mathbf{j}, \pm\mathbf{k}\}$ sitting inside the quaternions $\mathbb{H}$ of Definition 13.12.3 under multiplication. Both have five conjugacy classes and degrees $1, 1, 1, 1, 2$, and their tables agree entry for entry, yet the groups are not isomorphic. **This is stated on credit and not proved here**; nothing below depends on it. What the character table *does* determine is every complex representation of the group, up to equivalence (Corollary 22.8.8).

22.8.8 Exercises

22.8.8.1 A. Check your understanding

Exercise A1.

(a) Define the character of a representation, and state why it does not depend on a choice of basis.

(b) State the orthogonality relation for irreducible complex characters.

(c) Determine whether the following is true: "if χ is a character of G then $\chi(gh) = \chi(g)\chi(h)$." Justify your answer.

(d) A group of order 12 has exactly four conjugacy classes. Determine the degrees of its irreducible complex representations.

(e) Explain why the number of irreducible complex representations of an abelian group G is $|G|$.

Solution.

(a) $\chi_\rho(g) = \operatorname{tr}\rho(g)$ (Definition 22.8.2). The trace of an operator is computed from its matrix in any basis and the answer is the same for all of them (Definition 3.10.2), so χ_ρ depends only on ρ.

(b) For irreducible complex representations ρ, σ of a finite group, $\langle \chi_\sigma, \chi_\rho \rangle$ is 1 if $\rho \cong \sigma$ and 0 otherwise (Theorem 22.8.7).

(c) False. See the warning after Proposition 22.8.2: for the standard representation of S_3, $\chi((1\ 2))\chi((1\ 3)) = 0$ but $\chi((1\ 3\ 2)) = -1$. It is true precisely for characters of degree 1.

(d) Four classes means four irreducible representations (Theorem 22.8.9), with degrees $d_1, \dots, d_4 \geq 1$ satisfying $d_1^2 + d_2^2 + d_3^2 + d_4^2 = 12$ (Corollary 22.8.10). Every group has the trivial representation, so we may take $d_1 = 1$ and need $d_2^2 + d_3^2 + d_4^2 = 11$ with each $d_i \geq 1$. The squares available are $1, 4, 9$, since $4^2 = 16 > 11$. A triple containing a 9 has its other two terms summing to 2, so it is $9+1+1 = 11$, which works; and a triple with no 9 is one of $4+4+4 = 12$, $4+4+1 = 9$, $4+1+1 = 6$ and $1+1+1 = 3$, none of them 11. So the degrees are $1, 1, 1, 3$.

(e) In an abelian group $xgx^{-1} = g$, so every conjugacy class is a singleton and $k = |G|$; now apply Theorem 22.8.9.

22.8.8.2 B. Practice

Exercise B1: A character computed and decomposed.

Let $\mathbf{P}_\tau$ be the permutation matrix of $\tau \in S_3$, so that $\mathbf{P}_\tau \mathbf{e}_i = \mathbf{e}_{\tau(i)}$ (Definition 2.6.2), and let π be the representation of S_3 on $\mathcal{L}(\mathbb{C}^3)$ given by $\pi(\tau)(f) = \mathbf{P}_\tau f \mathbf{P}_\tau^{-1}$.

(a) Compute the character of π on the three conjugacy classes.

(b) Decompose π into irreducibles.

Solution.

(a) This is the construction of Proposition 22.8.6 with both representations equal to the permutation representation ρ_{perm} on $\mathbb{C}^3$. So its character is $\chi_\pi(\tau) = \chi_{\text{perm}}(\tau)\overline{\chi_{\text{perm}}(\tau)} = |\chi_{\text{perm}}(\tau)|^2$. From Example (Checking the standard representation by its character), $\chi_{\text{perm}} = (3, 1, 0)$ on the classes of id, $(1\ 2)$, $(1\ 2\ 3)$, so $\chi_\pi = (9, 1, 0)$.

(b) With weights $1, 3, 2$ and divisor 6:

$$\begin{aligned} \langle \chi_\pi, \chi_{\text{triv}} \rangle &= \tfrac{1}{6}(9 + 3 + 0) = 2, \\ \langle \chi_\pi, \chi_{\text{sgn}} \rangle &= \tfrac{1}{6}(9 - 3 + 0) = 1, \\ \langle \chi_\pi, \chi_{\text{std}} \rangle &= \tfrac{1}{6}(9 \cdot 2 + 0 + 0) = 3. \end{aligned}$$

So $\chi_\pi = 2\chi_{\text{triv}} + \chi_{\text{sgn}} + 3\chi_{\text{std}}$, and the degrees check: $2 + 1 + 6 = 9 = \dim \mathcal{L}(\mathbb{C}^3)$. As a check on the arithmetic, $\langle \chi_\pi, \chi_\pi \rangle = \frac{1}{6}(81 + 3 + 0) = 14 = 2^2 + 1^2 + 3^2$, as Corollary 22.8.8 requires. In particular $\dim \mathcal{L}_G(\mathbb{C}^3, \mathbb{C}^3) = 2$: the G-equivariant operators on $\mathbb{C}^3$ form a plane, spanned by the identity and the all-ones matrix.

Exercise B2: Which of these are characters?.

Let $G = S_3$, with classes ordered id, (1 2), (1 2 3) of sizes $1, 3, 2$. Determine which of the following class functions are characters of complex representations of S_3. Justify your answer.

(a) $(4, 0, 1)$;
(b) $(3, 1, 0)$;
(c) $(2, 2, -1)$;
(d) $(1, 1, -1)$.

Solution. A class function is a character exactly when it is a **non-negative integer** combination of $\chi_{\text{triv}} = (1, 1, 1)$, $\chi_{\text{sgn}} = (1, -1, 1)$ and $\chi_{\text{std}} = (2, 0, -1)$, by Corollary 22.7.4 and Proposition 22.8.2 (d); the coefficients are the inner products $\langle \cdot, \chi_i \rangle$.

(a) $\langle (4,0,1), \chi_{\text{triv}} \rangle = \frac{1}{6}(4 + 0 + 2) = 1$, $\langle \cdot, \chi_{\text{sgn}} \rangle = \frac{1}{6}(4 - 0 + 2) = 1$, $\langle \cdot, \chi_{\text{std}} \rangle = \frac{1}{6}(8 + 0 - 2) = 1$. All non-negative integers, and $1 \cdot 1 + 1 \cdot 1 + 1 \cdot 2 = 4$ matches the degree. **Yes**: it is the character of the direct sum of the trivial, the sign and the standard representation, equivalently of the direct sum of the permutation representation and the sign representation, since $(3, 1, 0) + (1, -1, 1) = (4, 0, 1)$.
(b) Inner products $1, 0, 1$ as computed in Example (Checking the standard representation by its character). **Yes**: the permutation representation.
(c) $\langle \cdot, \chi_{\text{triv}} \rangle = \frac{1}{6}(2 + 6 - 2) = 1$, $\langle \cdot, \chi_{\text{sgn}} \rangle = \frac{1}{6}(2 - 6 - 2) = -1$. A negative multiplicity is impossible, so **no**. (It is a difference of characters, called a virtual character, but not a character.)
(d) $\langle (1,1,-1), \chi_{\text{triv}} \rangle = \frac{1}{6}(1 + 3 - 2) = \frac{1}{3}$, which is not an integer. So **no**: it is not even a combination of the three irreducible characters with integer coefficients, let alone non-negative ones.

Exercise B3: Degree-one characters of a cyclic group.

Let $G = \mathbb{Z}/6\mathbb{Z}$.

(a) Write down the character table.
(b) Verify $\langle \chi_1, \chi_4 \rangle = 0$ and $\langle \chi_2, \chi_2 \rangle = 1$ by direct computation.

Solution.

(a) The group is abelian of order 6, so there are six classes, six irreducible characters, all of degree 1, given by $\chi_m([j]) = \omega^{jm}$ with $\omega = e^{2\pi i/6}$ (Example (The irreducible complex representations of a cyclic group)). The table has (m, j)-entry ω^{jm}, with $\omega^6 = 1$.
(b) $\langle \chi_1, \chi_4 \rangle = \frac{1}{6}\sum_{j=0}^{5} \omega^j \overline{\omega^{4j}} = \frac{1}{6}\sum_j \omega^{-3j} = \frac{1}{6}\sum_j (-1)^j = \frac{1}{6}(1 - 1 + 1 - 1 + 1 - 1) = 0$, using $\omega^{-3} = \omega^3 = -1$. And $\langle \chi_2, \chi_2 \rangle = \frac{1}{6}\sum_j \omega^{2j}\overline{\omega^{2j}} = \frac{1}{6}\sum_j |\omega^{2j}|^2 = \frac{1}{6} \cdot 6 = 1$.

22.8.8.3 C. Going deeper

Exercise C1: Counting fixed points.

Let G be a finite group acting on $\{1,\dots,n\}$ through a homomorphism $\varphi\colon G\to S_n$, and let $\rho(g)=\mathbf{P}_{\varphi(g)}$ be the corresponding permutation representation on $\mathbb{C}^n$, where $\mathbf{P}_\sigma$ is the permutation matrix of Definition 2.6.2 (so $\mathbf{P}_\sigma\mathbf{P}_\tau=\mathbf{P}_{\sigma\tau}$ by Lemma 2.6.6 (a)).

(a) Prove that $\langle\chi_\rho,\chi_{\mathrm{triv}}\rangle$ equals the average number of fixed points of the permutations $\varphi(g)$, and also equals $\dim(\mathbb{C}^n)^G$.

(b) Deduce that for every $n\ge 1$, the average number of fixed points of a permutation in S_n is exactly 1.

(c) For $G=S_3$ with $\varphi=\mathrm{id}$, verify (a) numerically.

Solution.

(a) By the computation after Definition 22.8.2, $\chi_\rho(g)$ is the number of i with $\varphi(g)(i)=i$. Hence

$$\langle\chi_\rho,\chi_{\mathrm{triv}}\rangle=\frac{1}{|G|}\sum_{g}\chi_\rho(g)\cdot\overline{1}$$

is exactly the average of those counts. By Lemma 22.8.4 applied to ρ, the same quantity is $\dim(\mathbb{C}^n)^G$.

(b) Take $G=S_n$ and $\varphi=\mathrm{id}$. A vector $\mathbf{x}\in\mathbb{C}^n$ fixed by every $\rho(\tau)$ has $x_i=x_j$ for all $i\neq j$, by taking τ the transposition $(i\ j)$; conversely every vector with equal coordinates is fixed. So $(\mathbb{C}^n)^{S_n}=\mathrm{span}(\mathbf{e}_1+\cdots+\mathbf{e}_n)$, of dimension 1 (for $n=1$ this is $\mathbb{C}$ itself). By (a) the average number of fixed points equals that dimension, namely 1.

(c) For S_3, $\chi_\rho=(3,1,0)$ on classes of sizes $1,3,2$, so the average number of fixed points is $\frac{1}{6}(1\cdot 3+3\cdot 1+2\cdot 0)=1$. Directly: id fixes three points, each of the three transpositions fixes one, and each of the two 3-cycles fixes none, giving $(3+3+0)/6=1$. And $\dim(\mathbb{C}^3)^{S_3}=1$ by (b). The three agree.

Exercise C2: Degree-one characters form a group.

Let G be a finite group and let $X(G)$ be the set of characters of degree 1 of complex representations of G. (For abelian G this group is the subject of Section 09.)

(a) Prove that the pointwise product of two degree-one characters is a degree-one character, and that $X(G)$ is a group under this product.

(b) Prove that $|X(G)|\le k$, the number of conjugacy classes, with equality if and only if G is abelian. *Hint: use Corollary 22.8.10 in one direction and Corollary 22.4.4 in the other.*

Solution.

(a) A degree-one character is a homomorphism $\chi\colon G\to\mathbb{C}\setminus\{0\}$ (the representation *is* the scalar it multiplies by). If χ,ψ are two of them then $(\chi\psi)(gh)=\chi(gh)\psi(gh)=\chi(g)\psi(g)\chi(h)\psi(h)=(\chi\psi)(g)(\chi\psi)(h)$, using commutativity of $\mathbb{C}$; so $\chi\psi$ is again a homomorphism into $\mathbb{C}\setminus\{0\}$, hence a degree-one character. The product is associative because multiplication in $\mathbb{C}$ is; χ_{triv} is an identity; and $g\mapsto\chi(g)^{-1}$ is a homomorphism and satisfies $\chi\cdot\chi^{-1}=\chi_{\mathrm{triv}}$. So $X(G)$ is a group (Definition 0.10.1).

(b) Degree-one characters are irreducible (a one-dimensional representation has no non-trivial invariant subspace) and pairwise distinct elements of $X(G)$ are inequivalent representations, since for degree one, equivalence means equality. So $X(G)$ is a subset of the k irreducible characters (Theorem 22.8.9) and $|X(G)| \le k$.

Equality says every irreducible character has degree 1. If G is abelian then $\mathbb{C}[G]$ is a commutative algebra, so every irreducible $\mathbb{C}[G]$-space is one-dimensional by Corollary 22.4.4; by Theorem 22.7.1 those are exactly the irreducible representations of G. Conversely, if every irreducible has degree 1 then $|G| = \sum_{i=1}^{k} 1 = k$ by Corollary 22.8.10, so every conjugacy class is a singleton; that is, $xgx^{-1} = g$ for all x, g, which says G is abelian.

Exercise C3: The second orthogonality relation.

Let G be a finite group with irreducible complex characters $\chi_1, \dots, \chi_k$.

(a) Prove that $\sum_{i=1}^{k} |\chi_i(g)|^2 = |G|/|C(g)|$ for every $g \in G$.

(b) Deduce that $\sum_i |\chi_i(g)|^2 = 1$ if and only if the class of g is all of G, and that this happens only for the trivial group. *Hint:* $C(1) = \{1\}$ *always.*

(c) For $G = S_3$ compute $\sum_i |\chi_i(g)|^2$ at each of the three classes and check (a).

Solution.

(a) This is the diagonal case $j = l$ of Corollary 22.8.11, with $g = g_j$ a representative of its own class and $c_j = |C(g)|$. The value is independent of the representative chosen, as it must be, since characters are class functions.

(b) By (a), the sum equals 1 exactly when $|C(g)| = |G|$, that is, when the class of g is all of G. But $C(1) = \{1\}$, and the classes partition G, so a class equal to G forces $G = \{1\}$. Conversely for the trivial group the only class is $\{1\} = G$ and the single character has $|\chi_1(1)|^2 = 1$.

(c) From Example (The character table of the symmetric group on three letters): at id, $1+1+4 = 6 = 6/1$; at (1 2), $1+1+0 = 2 = 6/3$; at (1 2 3), $1+1+1 = 3 = 6/2$. Each matches $|G|/|C(g)|$ with class sizes $1, 3, 2$.

22.9 Finite Abelian Groups and the Fourier Transform

Everything in this chapter has been building a machine, and for one family of groups the machine produces an object the book already owns. When G is abelian and the field is $\mathbb{C}$, Section 4 forces every irreducible representation down to a single dimension, Section 8 makes the resulting characters orthonormal, and what is left is one unitary matrix. For the cyclic group that matrix is the Fourier matrix of Chapter 11 Section 9, entry for entry. This section proves that, and two companion statements: the convolution theorem is the group algebra splitting into a product of copies of $\mathbb{C}$, and a circulant is an element of that group algebra multiplying.

Throughout, G is a **finite abelian** group, with identity written e, and the field is $\mathbb{C}$ unless a statement says otherwise. When $G = \mathbb{Z}/n\mathbb{Z}$ we follow Chapter 11 Section 9 and run every index

from 0 to $n-1$, reading subscripts modulo n. We write δ_g for the basis vector of the group algebra $\mathbb{C}[G]$ attached to $g \in G$ (Definition 22.1.5), so that $\delta_g \delta_h = \delta_{gh}$ and δ_e is the identity of the algebra; the Kronecker delta of Chapter 10 always carries two numerical subscripts, as in δ_{jk}, and no group element is ever written as a pair of numbers.

22.9.1 One dimension is all there is

Section 4 proved that over an algebraically closed field the irreducible representations of a commutative algebra are lines, and Section 7 turned representations of G into representations of $\mathbb{C}[G]$. Since G is abelian, $\mathbb{C}[G]$ is commutative, so the two results together leave no room: an irreducible complex representation of G is one-dimensional, and an operator on a line is a number. A character is then not merely a function on G; it is a homomorphism out of G.

Before that we recall the one fact about finite groups that Chapter 0 did not record: every g in a finite group has a least $m \geq 1$ with $g^m = e$, its **order**, and $\langle g \rangle = \{e, g, \dots, g^{m-1}\}$ is then a subgroup with exactly m elements. Section 8 proved it, as Lemma 22.8.1, writing the identity 1 where this section writes e; we use it constantly below.

A group of the form $\langle g \rangle$ gets a name, since it is the only shape of group we can handle in full.

Definition 22.9.1 — Cyclic group

A group G is **cyclic** if $G = \langle g \rangle$ for some $g \in G$; such a g is called a **generator** of G. A cyclic group is abelian, since $g^k g^l = g^{k+l} = g^l g^k$.

One construction of groups from groups is needed before the examples, and Chapter 0 did not record it either.

Definition 22.9.2 — Direct product of groups

Let G and H be groups. Their **direct product** $G \times H$ is the set of ordered pairs (g, h) with the componentwise operation $(g, h)(g', h') := (gg', hh')$. It is a group, with identity (e_G, e_H) and $(g, h)^{-1} = (g^{-1}, h^{-1})$; the three axioms are checked one component at a time. It is abelian when G and H are, and $|G \times H| = |G|\,|H|$.

By Lemma 22.8.1, a finite cyclic group $G = \langle g \rangle$ has $|G|$ equal to the order of g. The standard example is $\mathbb{Z}/n\mathbb{Z}$ under addition, generated by $[1]$, with $[1]$ of order n. The group $\mathbb{Z}$ is cyclic and infinite. The Klein four-group $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ is abelian but **not** cyclic: every element satisfies $x + x = 0$, so no element has order 4.

Now the theorem that starts the section.

Theorem 22.9.1 — Characters of an Abelian Group Are Homomorphisms

Let G be a finite abelian group and let the field be $\mathbb{C}$. Then:

(a) every irreducible representation of G is one-dimensional;

(b) a one-dimensional representation of G is the same thing as a group homomorphism $\chi\colon G \to \mathbb{C}^\times$, and the character of that representation is χ itself;

(c) every one-dimensional representation is irreducible, and two of them are equivalent if and only if they are equal;

(d) for every such χ and every $g \in G$, the number $\chi(g)$ is an m-th root of unity, where m is the order of g (Lemma 22.8.1); in particular $|\chi(g)| = 1$ and $\chi(g)^{-1} = \overline{\chi(g)} = \chi(g^{-1})$.

Idea. Only (a) is deep, and Section 4 did it: in a commutative algebra every element commutes with the whole algebra, so Schur's lemma (Theorem 22.4.1) makes every element act as a scalar, and then every line is invariant, so an irreducible representation can only be a line. The rest is bookkeeping about 1×1 matrices, together with the observation that a finite group makes every value a root of unity.

Proof.

(a) A representation of G over $\mathbb{C}$ is a representation of the algebra $\mathbb{C}[G]$ (Theorem 22.7.1), and $\mathbb{C}[G]$ is commutative because G is abelian: the products $\delta_g\delta_h = \delta_{gh}$ and $\delta_h\delta_g = \delta_{hg}$ agree on basis vectors, and the general case follows by bilinearity. Since $\mathbb{C}$ is algebraically closed, Corollary 22.4.4 applies and every irreducible representation is one-dimensional.

(b) Let $\rho\colon G \to \mathrm{GL}(V)$ with $\dim V = 1$. For each g the operator $\rho(g)$ maps the line V to itself, so $\rho(g) = \chi(g)\,\mathrm{id}_V$ for a unique scalar $\chi(g)$, and $\chi(g) \neq 0$ because $\rho(g)$ is invertible. From $\rho(gh) = \rho(g)\rho(h)$ we get $\chi(gh) = \chi(g)\chi(h)$, so $\chi\colon G \to \mathbb{C}^\times$ is a homomorphism (Definition 0.10.3). In any basis of V the matrix of $\rho(g)$ is the 1×1 matrix with entry $\chi(g)$, so its trace, which is the character (Definition 22.8.2), is $\chi(g)$. Conversely a homomorphism $\chi\colon G \to \mathbb{C}^\times$ defines a representation on $V = \mathbb{C}$ by $\rho(g)z = \chi(g)z$.

(c) A one-dimensional V has no subspaces but $\{\mathbf{0}\}$ and V, and $V \neq \{\mathbf{0}\}$, so there is no proper non-zero subrepresentation and ρ is irreducible (Definition 22.7.4). Suppose ρ, ρ' are one-dimensional with scalars χ, χ' and $T\colon V \to V'$ is an isomorphism with $T\rho(g) = \rho'(g)T$ for all g. Applying both sides to a non-zero $\mathbf{v} \in V$ gives $\chi(g)\,T\mathbf{v} = \chi'(g)\,T\mathbf{v}$, and $T\mathbf{v} \neq \mathbf{0}$, so $\chi = \chi'$. The converse is immediate with $T = \mathrm{id}$.

(d) By Lemma 22.8.1 there is $m \geq 1$ with $g^m = e$. Then

$$\chi(g)^m = \chi(g^m) = \chi(e) = 1$$

by Theorem 0.10.3, so $\chi(g)$ is an m-th root of unity (Example (Roots of Unity)). Taking absolute values, $|\chi(g)|^m = 1$ with $|\chi(g)|$ a positive real, so $|\chi(g)| = 1$ and therefore $\overline{\chi(g)} = \chi(g)^{-1}$. Finally $\chi(g)^{-1} = \chi(g^{-1})$, again by Theorem 0.10.3; this last identity is Proposition 22.8.2 (e) in the one-dimensional case.

■

Part (a) is where the field matters, and it matters twice over. It uses algebraic closure, and Section 4 exhibited what goes wrong without it: the rotation representation of a cyclic group on $\mathbb{R}^2$ is irreducible of dimension 2. Nothing in (a) needs a hypothesis on the characteristic; that hypothesis enters when we want representations to decompose, which is Maschke's theorem (Theorem 22.7.3), and again through Section 8, whose orthogonality relations are proved by

averaging over the group and need it too.

Example. (The characters of a cyclic group)

Let $G = \mathbb{Z}/n\mathbb{Z}$, written additively, and let $\omega := e^{2\pi i/n}$. Find all homomorphisms $G \to \mathbb{C}^\times$.

Solution. Section 7 did this, in Example (The irreducible complex representations of a cyclic group): such a χ is determined by $z := \chi([1])$, which satisfies $z^n = \chi([n]) = \chi([0]) = 1$ and so equals ω^j for exactly one $j \in \{0, \dots, n-1\}$ (Example (Roots of Unity)); and each j does give a homomorphism. So there are exactly n characters,

$$\chi_j([m]) = \omega^{jm} \qquad (j, m = 0, 1, \dots, n-1),$$

with χ_0 the constant function 1. What Section 7 obtained as a list of irreducible representations is, by Theorem 22.9.1 (b), the same list read as homomorphisms.

Example. (The Klein four-group)

Let $G = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, with elements written (x, y) for $x, y \in \{0, 1\}$. Find all characters and write down the resulting table.

Solution. Every element satisfies $2(x, y) = (0, 0)$, so $\chi(x, y)^2 = \chi\big(2(x, y)\big) = \chi(0, 0) = 1$ by Theorem 22.9.1 (b), and each value $\chi(x, y)$ is ± 1. A homomorphism is determined by $\chi(1, 0)$ and $\chi(0, 1)$, and any choice of signs for those two works: setting $\chi_{a,b}(x, y) := (-1)^{ax+by}$ for $a, b \in \{0, 1\}$ gives a homomorphism, because $(-1)^{a(x+x')+b(y+y')}$ factors and the exponent only matters modulo 2. So there are exactly four characters, and the table of values, with rows the characters and columns the elements in the order $(0, 0), (1, 0), (0, 1), (1, 1)$, is

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix},$$

the rows being $\chi_{0,0}, \chi_{1,0}, \chi_{0,1}, \chi_{1,1}$. Any two distinct rows agree in two places and disagree in two, so their entrywise product sums to 0: the rows are orthogonal, as Theorem 22.8.7 says they must be.

Warning. The word "character" is doing double duty, and only for abelian groups do the two jobs coincide. For a general finite group the character $\chi_\rho = \operatorname{tr} \rho$ of Definition 22.8.2 is **not** a homomorphism: $\chi_\rho(e) = \dim V$, which is 1 only when ρ is one-dimensional. The group S_3 has an irreducible complex representation of dimension 2 (Section 7), whose character takes the value 2 at the identity and is therefore not a homomorphism into $\mathbb{C}^\times$. Reserve "the characters of G" for the homomorphisms $G \to \mathbb{C}^\times$ only when G is abelian, which is what we do from here on.

Quick check. The group $\mathbb{Z}/3\mathbb{Z}$ has exactly one homomorphism into $\mathbb{R}^\times$. Which, and why does this not contradict Theorem 22.9.1?

Solution. If $\chi\colon \mathbb{Z}/3\mathbb{Z} \to \mathbb{R}^\times$ is a homomorphism, then $\chi([1])^3 = 1$ with $\chi([1])$ real, and the only real cube root of 1 is 1. So χ is trivial. There is no contradiction: Theorem 22.9.1

is a statement over $\mathbb{C}$, and its part (a) rests on algebraic closure. Over $\mathbb{R}$ the group $\mathbb{Z}/3\mathbb{Z}$ has an irreducible two-dimensional representation, by rotation through $2\pi/3$, and that representation has no one-dimensional pieces to contribute a character.

22.9.2 The dual group

The characters of G are now a set of functions on G, and that set has structure of its own: the pointwise product of two homomorphisms into an abelian group is again a homomorphism. So the characters form a group, and the rest of the section is about how that group compares with G.

The dual group of G is the group of ways to measure G by complex numbers of modulus one.

Definition 22.9.3 — Dual group

Let G be a finite abelian group. The **dual group** of G is

$$\widehat{G} := \{\, \chi \colon G \to \mathbb{C}^\times : \chi \text{ is a group homomorphism} \,\},$$

with the **pointwise** operation $(\chi\psi)(g) := \chi(g)\psi(g)$. Its elements are the **characters** of G.

In words: an element of $\widehat{G}$ is one homomorphism out of G, and two of them are multiplied by multiplying their values at each point separately. Nothing here refers to a representation any more; by Theorem 22.9.1 this is exactly the set of irreducible characters of G, repackaged so that it carries a product.

Proposition 22.9.2 — The Dual Group Is a Group

For a finite abelian group G, the set $\widehat{G}$ with the pointwise operation is a finite abelian group. Its identity is the **trivial character** χ_0, with $\chi_0(g) = 1$ for every g, and the inverse of χ is $\overline{\chi}$, the function $g \mapsto \overline{\chi(g)}$.

Proof. First, the operation lands in $\widehat{G}$: if $\chi, \psi \in \widehat{G}$ then

$$(\chi\psi)(gh) = \chi(g)\chi(h)\psi(g)\psi(h) = (\chi\psi)(g)\,(\chi\psi)(h),$$

where the first equality is that χ and ψ are homomorphisms and the second reorders the four factors, using that $\mathbb{C}^\times$ is commutative; so $\chi\psi \in \widehat{G}$. Associativity and commutativity hold pointwise because they hold in $\mathbb{C}^\times$. The constant function $\chi_0 = 1$ is a homomorphism and satisfies $\chi_0\chi = \chi$. For inverses, $\overline{\chi}$ is a homomorphism because conjugation is multiplicative, and $\chi(g)\overline{\chi(g)} = |\chi(g)|^2 = 1$ by Theorem 22.9.1 (d), so $\chi\overline{\chi} = \chi_0$. Finally $\widehat{G}$ is finite: a character is determined by its values on the $|G|$ elements of G, and each value $\chi(g)$ is an m-th root of unity, where m is the order of g and $m \le |G|$ (Lemma 22.8.1); there are only finitely many such numbers. This proves the proposition. ∎

How big is $\widehat{G}$? Section 8 already answered this, and the answer costs one observation about

abelian groups.

Proposition 22.9.3 — The Dual Group Has the Same Size

For every finite abelian group G, $|\widehat{G}| = |G|$.

Proof. Two elements $g, h \in G$ are conjugate when $h = xgx^{-1}$ for some $x \in G$ (Definition 22.8.1). In an abelian group $xgx^{-1} = gxx^{-1} = g$, so each conjugacy class is a single element and G has exactly $|G|$ conjugacy classes. By Theorem 22.8.9 the number of irreducible complex characters of G equals the number of conjugacy classes, hence it is $|G|$. By Theorem 22.9.1 (b) and (c), the irreducible characters are precisely the elements of $\widehat{G}$, each arising from one equivalence class of irreducible representations. So $|\widehat{G}| = |G|$.

■

That is a statement about cardinality. The stronger statement is that $\widehat{G}$ and G are isomorphic as groups, and here the book runs into a limit it should name rather than hide. We can prove it for cyclic groups, and we can prove that it survives taking products; and that is as far as Chapter 0's group theory reaches.

Theorem 22.9.4 — The Dual of a Product of Cyclic Groups

Let G and H be finite abelian groups. Then:

(a) if G is cyclic, then $\widehat{G} \cong G$;

(b) $\widehat{G \times H} \cong \widehat{G} \times \widehat{H}$;

(c) consequently, if G is a direct product of finitely many finite cyclic groups, then $\widehat{G} \cong G$.

Idea. For (a), a homomorphism out of $\langle g \rangle$ is decided by one value, and that value may be any n-th root of unity; so the dual is listed by the same n exponents that list G, and matching exponent to exponent is the isomorphism. For (b), a character of a product splits into its two restrictions, and multiplying the restrictions back together recovers it. Part (c) is then induction on the number of factors.

Proof.

(a) Let $G = \langle g \rangle$ with $|G| = n$, so g has order n (Lemma 22.8.1), and put $\omega = e^{2\pi i/n}$. For $j \in \mathbb{Z}$ define $\chi_j(g^k) := \omega^{jk}$. This is well defined: if $g^k = g^l$ then $n \mid k - l$, so $\omega^{jk} = \omega^{jl}$. It is a homomorphism, since $\omega^{j(k+l)} = \omega^{jk}\omega^{jl}$, so $\chi_j \in \widehat{G}$.
Now define $\Theta\colon G \to \widehat{G}$ by $\Theta(g^j) := \chi_j$. It is well defined by the same divisibility: $n \mid j - j'$ gives $\omega^{jk} = \omega^{j'k}$ for every k, so $\chi_j = \chi_{j'}$. It is a homomorphism, because $\chi_j\chi_{j'}$ sends g^k to $\omega^{jk}\omega^{j'k} = \omega^{(j+j')k}$, which is $\chi_{j+j'}(g^k)$. It is injective: if $\Theta(g^j) = \chi_0$ then $\omega^j = \chi_j(g) = 1$, so $n \mid j$ and $g^j = e$; and a homomorphism with trivial kernel is injective, since $\Theta(x) = \Theta(y)$ gives $\Theta(xy^{-1}) = \chi_0$ by Theorem 0.10.3. It is surjective: given $\chi \in \widehat{G}$, we have $\chi(g)^n = \chi(g^n) = \chi(e) = 1$, so $\chi(g) = \omega^j$ for some j (Example (Roots of Unity)), and then $\chi(g^k) = \omega^{jk} = \chi_j(g^k)$ for every k, so $\chi = \chi_j = \Theta(g^j)$. Hence Θ is an isomorphism.

(b) Define $\Xi\colon \widehat{G}\times\widehat{H}\to\widehat{G\times H}$ by letting $\Xi(\chi,\psi)$ be the function $(g,h)\mapsto\chi(g)\psi(h)$. That function is a homomorphism, since

$$\chi(gg')\psi(hh')=\big(\chi(g)\psi(h)\big)\big(\chi(g')\psi(h')\big),$$

using commutativity of $\mathbb{C}^\times$. The map Ξ is a homomorphism of groups because both sides are computed pointwise. It is injective: if $\chi(g)\psi(h)=1$ for all g,h, then taking $h=e_H$ gives $\chi(g)=1$ for all g, whence also $\psi=\chi_0$; so the kernel is trivial and Ξ is injective, for the reason given in (a). It is surjective: given $\theta\in\widehat{G\times H}$, set $\chi(g)\coloneqq\theta(g,e_H)$ and $\psi(h)\coloneqq\theta(e_G,h)$, both homomorphisms; then

$$\theta(g,h)=\theta\big((g,e_H)(e_G,h)\big)=\chi(g)\psi(h),$$

so $\theta=\Xi(\chi,\psi)$. Hence Ξ is an isomorphism.

(c) Induct on the number r of factors. For $r=1$ this is (a). If $G=G_1\times\cdots\times G_r$ with each G_i cyclic, write $G=G_1\times K$ with $K=G_2\times\cdots\times G_r$. By (b), $\widehat{G}\cong\widehat{G_1}\times\widehat{K}$, which by (a) and the inductive hypothesis is isomorphic to $G_1\times K=G$.

■

Remark. The chapter can go no further here, and it should say so. It is true that **every** finite abelian group is a direct product of cyclic groups, so that $\widehat{G}\cong G$ for every finite abelian G. That structure theorem is **not proved in this book**, and nothing below depends on it: every later statement of this section is either about a cyclic group or uses only Proposition 22.9.3, which is proved. The linear-algebra shadow of the structure theorem is in Chapter 9 Section 7: Theorem 9.7.3 diagonalizes a matrix over $F[x]$ with a divisibility chain, and the identical argument over $\mathbb{Z}$ turns a matrix of relations between generators of a finite abelian group into a list of cyclic factors. Chapter 9 sets that out as Exercise (C1: The same algorithm over the integers), and an exercise is not a proof; the input it assumes, that a finite abelian group is presentable by an integer relation matrix at all, is also not proved there.

Warning. The isomorphism $\widehat{G}\cong G$ of Theorem 22.9.4 is **not canonical**: the map Θ in the proof depends on choosing a generator g of G and a primitive root of unity ω, and different choices give different isomorphisms. There is no way to remove the choice. What *is* canonical is the isomorphism from G to its **double** dual, $g\mapsto(\chi\mapsto\chi(g))$, which mentions no choices at all; Exercise (C2: The double dual needs no choices) asks you to prove it. This is the same phenomenon as Chapter 4's $V\cong V^*$ against $V\cong V^{**}$, and it is not a coincidence.

Quick check. Why does Proposition 22.9.3 fail for S_3 if "character" is read as "homomorphism into $\mathbb{C}^\times$"?

Solution. Because Proposition 22.9.3 used that every conjugacy class of an abelian group is a single element. In S_3 there are three classes, not six, so there are three irreducible characters; and of those only two are one-dimensional, so the set of homomorphisms $S_3\to\mathbb{C}^\times$ has two elements, not six. The proof breaks at the first line, not the last.

22.9.3 The character matrix, the transform, and inversion

With $|\widehat{G}| = |G| = n$ we may line the two sets up and form a square matrix of values. Everything the section is heading towards is a statement about that one matrix.

Definition 22.9.4 — Character matrix

Let G be a finite abelian group of order n. Fix an ordering $g_0, \dots, g_{n-1}$ of G and an ordering $\chi_0, \dots, \chi_{n-1}$ of $\widehat{G}$, which has n elements too (Proposition 22.9.3). The **character matrix** of G for those orderings is $\mathbf{U} \in M_n(\mathbb{C})$ with

$$(\mathbf{U})_{mj} := \frac{\chi_j(g_m)}{\sqrt{n}} \qquad (0 \le m, j \le n-1).$$

Its j-th column lists the values of χ_j, scaled by $n^{-1/2}$.

Section 8 rescaled the same table the other way up: the matrix in the proof of Corollary 22.8.11 has the characters along its **rows**, and is the transpose of this $\mathbf{U}$ once every class size c_j is 1, which for an abelian G it is.

The scaling is there for one reason, and the next theorem is that reason. Alongside it we name the transform.

Definition 22.9.5 — Fourier transform on a finite abelian group

Let G be a finite abelian group of order n and let $f\colon G \to \mathbb{C}$. The **Fourier transform** of f is the function $\widehat{f}\colon \widehat{G} \to \mathbb{C}$ given by

$$\widehat{f}(\chi) := \sum_{g \in G} f(g)\,\chi(g).$$

Theorem 22.9.5 — Fourier Inversion on a Finite Abelian Group

Let G be a finite abelian group of order n, with orderings fixed as in Definition 22.9.4 and character matrix $\mathbf{U}$. Then:

(a) $\mathbf{U}$ is unitary, and the n functions $n^{-1/2}\chi_j$ form an orthonormal basis of the space $\mathbb{C}^G$ of all functions $G \to \mathbb{C}$;

(b) **(Inversion)** every $f\colon G \to \mathbb{C}$ satisfies

$$f(g) = \frac{1}{n} \sum_{\chi \in \widehat{G}} \widehat{f}(\chi)\,\overline{\chi(g)} \qquad (g \in G);$$

(c) **(Plancherel)** $\displaystyle\sum_{g \in G} |f(g)|^2 = \frac{1}{n} \sum_{\chi \in \widehat{G}} \bigl|\widehat{f}(\chi)\bigr|^2.$

Idea. Identify a function on G with its column of values, so that $\mathbb{C}^G$ becomes $\mathbb{C}^n$ with the standard inner product. Orthonormality of the characters, which Section 8 proved by averaging and Schur's lemma (Theorem 22.4.1), then says exactly that the columns of $\mathbf{U}$ are an orthonormal basis. Inversion and Plancherel are what a unitary matrix always gives: expand in the new basis, and lengths do not change.

Proof.

(a) Identify $f \in \mathbb{C}^G$ with the column $\mathbf{x} \in \mathbb{C}^n$, $x_m = f(g_m)$. Under this identification the standard inner product on $\mathbb{C}^n$ is $\langle f, f' \rangle = \sum_g f(g)\overline{f'(g)}$. The j-th column of $\mathbf{U}$ is the function $n^{-1/2}\chi_j$, and for any j, k,

$$\langle \tfrac{\chi_j}{\sqrt{n}}, \tfrac{\chi_k}{\sqrt{n}} \rangle = \frac{1}{n} \sum_{g \in G} \chi_j(g)\overline{\chi_k(g)},$$

which is the inner product of class functions of Definition 22.8.4 applied to χ_j and χ_k. By Theorem 22.9.1 (b) and (c) these are irreducible characters, of inequivalent representations when $j \neq k$, so the value is δ_{jk} by Theorem 22.8.7. Hence the columns of $\mathbf{U}$ are orthonormal; there are n of them in $\mathbb{C}^n$, so they form an orthonormal basis (Theorem 10.1.4, Theorem 1.6.4), and $\mathbf{U}$ is unitary (Theorem 10.7.3).

(b) Write $\mathbf{y} \in \mathbb{C}^n$ for the column with $y_j = n^{-1/2}\widehat{f}(\chi_j)$. By Definition 22.9.5,

$$y_j = \frac{1}{\sqrt{n}} \sum_m f(g_m)\chi_j(g_m) = \sum_m (\mathbf{U})_{mj}\, x_m,$$

that is $\mathbf{y} = \mathbf{U}^{\top}\mathbf{x}$. Now $\mathbf{U}^{\top}$ is unitary as well, since $(\mathbf{U}^{\top})^{*}\mathbf{U}^{\top} = \overline{\mathbf{U}}\,\mathbf{U}^{\top} = \overline{\mathbf{U}\,\mathbf{U}^{*}} = \mathbf{I}$, so $\mathbf{x} = (\mathbf{U}^{\top})^{*}\mathbf{y} = \overline{\mathbf{U}}\,\mathbf{y}$. Reading off entry m,

$$f(g_m) = \sum_j \overline{(\mathbf{U})_{mj}}\, y_j = \frac{1}{n} \sum_j \widehat{f}(\chi_j)\,\overline{\chi_j(g_m)},$$

which is the stated formula.

(c) A unitary matrix preserves the norm (Theorem 10.7.3), so $\|\mathbf{y}\|^2 = \|\mathbf{x}\|^2$. Here $\|\mathbf{x}\|^2 = \sum_g |f(g)|^2$ and $\|\mathbf{y}\|^2 = \frac{1}{n}\sum_j |\widehat{f}(\chi_j)|^2$. This proves the theorem.

■

Two remarks on conventions, both harmless. Some authors put a conjugate into the transform, defining $\widehat{f}(\chi) = \sum_g f(g)\overline{\chi(g)}$; since $\overline{\chi} = \chi^{-1} \in \widehat{G}$ (Proposition 22.9.2), this only relabels $\widehat{G}$ by inversion, and the inversion formula swaps its conjugate accordingly. We use the version without the conjugate because it is the one Chapter 11 already wrote down. Second, the $n^{-1/2}$ sits in $\mathbf{U}$ and not in $\widehat{f}$, which is again Chapter 11's choice.

22.9.4 The cyclic group is Chapter 11

Now take $G = \mathbb{Z}/n\mathbb{Z}$, ordered by $g_m = [m]$, with the characters $\chi_j([m]) = \omega^{jm}$ of Example (The characters of a cyclic group) in that order, and $\omega = e^{2\pi i/n}$. Three theorems follow, and together they say that the discrete Fourier transform of Chapter 11 was representation theory all along.

Theorem 22.9.6 — The Character Matrix Is the Fourier Matrix

For $G = \mathbb{Z}/n\mathbb{Z}$ with the orderings above, the character matrix of Definition 22.9.4 is exactly the Fourier matrix $\mathbf{F}$ of Theorem 11.9.3:

$$(\mathbf{U})_{mj} = \frac{\omega^{jm}}{\sqrt{n}} = (\mathbf{F})_{mj} \qquad (0 \le m, j \le n-1).$$

In particular the unitarity of $\mathbf{F}$ and the orthonormality of the characters of $\mathbb{Z}/n\mathbb{Z}$ are the same statement.

Proof. By Definition 22.9.4 and Example (The characters of a cyclic group), $(\mathbf{U})_{mj} = \chi_j(g_m)/\sqrt{n} = \omega^{jm}/\sqrt{n}$. By Theorem 11.9.3, $(\mathbf{F})_{mj} = \omega^{mj}/\sqrt{n}$. The two agree because $jm = mj$. The final sentence is Theorem 22.9.5 (a) read for this $\mathbf{U}$.

■

That last sentence deserves to be dwelt on, because the book has now proved the same fact twice by genuinely different routes. Chapter 11 proved $\mathbf{F}^*\mathbf{F} = \mathbf{I}$ by summing a geometric series: for $z^n = 1$ and $z \neq 1$, $1 + z + \cdots + z^{n-1} = 0$. Section 8 proved orthonormality of irreducible characters by averaging an arbitrary linear map over the group and applying Schur's lemma. The first argument is a computation that happens to come out; the second says why it had to. Neither is redundant, and the second does not make the first obsolete, since the first is what you use to compute.

Theorem 22.9.7 — The Group Algebra of an Abelian Group Splits

Let G be a finite abelian group of order n, and let $\mathbb{C}^{\widehat{G}}$ denote the algebra of all functions $\widehat{G} \to \mathbb{C}$ with pointwise operations, which is a product of n copies of $\mathbb{C}$. Then

$$\Phi\colon \mathbb{C}[G] \to \mathbb{C}^{\widehat{G}}, \qquad \Phi\Big(\sum_{g} c_g \delta_g\Big)(\chi) := \sum_{g} c_g\, \chi(g),$$

is an isomorphism of algebras. For $G = \mathbb{Z}/n\mathbb{Z}$ it is the discrete Fourier transform $\mathbf{c} \mapsto \widehat{\mathbf{c}} = \sqrt{n}\,\mathbf{F}\mathbf{c}$ of Chapter 11 Section 9, and its multiplicativity is Theorem 11.9.6 (b).

Idea. The map is multiplicative for one reason only: $\chi(gh) = \chi(g)\chi(h)$, so evaluating a character on a product of group algebra elements factors. Bijectivity is not a separate argument either; the matrix of Φ in the obvious bases is the character matrix up to transposing and scaling, and that matrix is unitary.

Proof. Write $a = \sum_g c_g \delta_g$ and $b = \sum_h d_h \delta_h$ in $\mathbb{C}[G]$ (Definition 22.1.5), so that $ab = \sum_{g,h} c_g d_h\, \delta_{gh}$. The map Φ is linear in a by construction. For multiplicativity, evaluate at $\chi \in \widehat{G}$:

$$\begin{aligned} \Phi(ab)(\chi) &= \sum_{g,h} c_g d_h\, \chi(gh) = \sum_{g,h} c_g d_h\, \chi(g)\chi(h) \\ &= \Big(\sum_g c_g \chi(g)\Big)\Big(\sum_h d_h \chi(h)\Big) = \Phi(a)(\chi)\,\Phi(b)(\chi), \end{aligned}$$

the second equality because χ is a homomorphism. The identity of $\mathbb{C}[G]$ is δ_e, and

$\Phi(\delta_e)(\chi) = \chi(e) = 1$ for every χ, which is the identity of $\mathbb{C}^{\widehat{G}}$. So Φ is a homomorphism of algebras (Definition 22.1.2).

For bijectivity, order G and $\widehat{G}$ as in Definition 22.9.4. In the basis $(\delta_{g_0}, \dots, \delta_{g_{n-1}})$ of $\mathbb{C}[G]$ and the basis of point masses on $\widehat{G}$, the matrix of Φ has (j, m)-entry $\chi_j(g_m) = \sqrt{n}\,(\mathbf{U})_{mj}$; that is, the matrix is $\sqrt{n}\,\mathbf{U}^{\top}$. By Theorem 22.9.5 (a), $\mathbf{U}$ is unitary, hence invertible, hence so is $\sqrt{n}\,\mathbf{U}^{\top}$. A linear bijection that is a homomorphism of algebras is an isomorphism of algebras.

For $G = \mathbb{Z}/n\mathbb{Z}$, write $a = \sum_m c_m \delta_{[m]}$. Then $\Phi(a)(\chi_j) = \sum_m c_m \omega^{jm} = p_{\mathbf{c}}(\omega^j)$, the j-th entry of the vector $\widehat{\mathbf{c}} = \sqrt{n}\,\mathbf{F}\mathbf{c}$ of Chapter 11 Section 9, with $p_{\mathbf{c}}$ the symbol of Definition 11.9.1. Multiplicativity of Φ then reads $p_{\mathbf{c}*\mathbf{d}}(\omega^j) = p_{\mathbf{c}}(\omega^j) p_{\mathbf{d}}(\omega^j)$, which is Theorem 11.9.6 (b).

■

So the convolution theorem is a splitting theorem. Convolution is hard to look at because it is multiplication in $\mathbb{C}[G]$ written in the basis of point masses; in the basis of characters the same multiplication is diagonal, because there the algebra has fallen apart into n independent copies of $\mathbb{C}$. Seen from Section 6 this is no surprise: $\mathbb{C}[G]$ is semisimple by Theorem 22.7.3 applied to the regular representation, and a commutative semisimple algebra over $\mathbb{C}$ is a product of matrix algebras by Theorem 22.6.1, all of whose blocks must be 1×1 because $M_k(\mathbb{C})$ is commutative only for $k = 1$. Then $\dim \mathbb{C}[G] = |G|$ and Corollary 22.6.2 force the number of blocks to be $|G|$. The content of Theorem 22.9.7 over and above that is the explicit isomorphism.

The third identification puts Chapter 11's matrices back into the picture.

Theorem 22.9.8 — Circulants Are the Group Algebra of the Cyclic Group

Let $n \geq 1$ and let $\mathcal{C}_n \subseteq M_n(\mathbb{C})$ be the algebra of circulants (Corollary 11.9.5). Let $\Psi \colon \mathbb{C}[\mathbb{Z}/n\mathbb{Z}] \to M_n(\mathbb{C})$ be the linear map with

$$\Psi(\delta_{[m]}) \coloneqq \mathbf{S}^m \qquad (m = 0, 1, \dots, n-1),$$

where $\mathbf{S}$ is the cyclic shift. Then:

(a) Ψ is an isomorphism of algebras onto $\mathcal{C}_n$, and $\Psi\big(\sum_m c_m \delta_{[m]}\big)$ is the circulant $\mathbf{C}$ with first row $\mathbf{c}$;

(b) $\Psi(a)$ is the matrix of the map "multiply by a" on $\mathbb{C}[\mathbb{Z}/n\mathbb{Z}]$, in the ordered basis

$$\mathcal{B} = \big(\delta_{[0]},\ \delta_{[-1]},\ \delta_{[-2]},\ \dots,\ \delta_{[-(n-1)]}\big);$$

(c) $\mathbf{F}^{*}\Psi(a)\mathbf{F}$ is the diagonal matrix whose j-th entry is $\Phi(a)(\chi_j)$; that is, Φ is Ψ followed by conjugating with $\mathbf{F}$ and reading off the diagonal.

Idea. Part (a) is almost a tautology once the right map is chosen: Ψ sends the basis element $\delta_{[m]}$ to $\mathbf{S}^m$, and the only relation in the group, $[m]+[k] = [m+k]$ read modulo n, matches the only relation among the powers, $\mathbf{S}^n = \mathbf{I}$. Part (b) is an index computation, and the reversal of the basis in it is forced by Chapter 11's convention $(\mathbf{C})_{jk} = c_{k-j}$. Part (c) is Theorem 11.9.4 restated.

Proof.

(a) By Theorem 11.9.1 (a), $\sum_m c_m \mathbf{S}^m = p_{\mathbf{c}}(\mathbf{S})$ is the circulant with first row $\mathbf{c}$, so Ψ has the stated values and its image is $\mathcal{C}_n$, which by Corollary 11.9.5 (a) has $\mathbf{I}, \mathbf{S}, \dots, \mathbf{S}^{n-1}$ as a basis. Hence Ψ carries a basis to a basis and is a linear bijection onto $\mathcal{C}_n$. For multiplicativity it suffices, by bilinearity of both products, to check it on basis vectors:

$$\Psi\big(\delta_{[m]}\delta_{[k]}\big) = \Psi\big(\delta_{[m+k]}\big) = \mathbf{S}^{(m+k) \bmod n} = \mathbf{S}^m\mathbf{S}^k,$$

the last equality because $\mathbf{S}^n = \mathbf{I}$. Finally $\Psi(\delta_{[0]}) = \mathbf{I}$, so Ψ is an isomorphism of algebras onto $\mathcal{C}_n$.

(b) Write $\mathcal{B} = (u_0, \dots, u_{n-1})$ with $u_k = \delta_{[-k]}$; this is a reordering of the basis of point masses, hence a basis. For $a = \sum_m c_m \delta_{[m]}$,

$$a\, u_k = \sum_m c_m\, \delta_{[m-k]} = \sum_m c_m\, u_{k-m} = \sum_j c_{k-j}\, u_j,$$

substituting $j = k - m$ and reading all subscripts modulo n. So the (j,k)-entry of the matrix of multiplication by a in $\mathcal{B}$ is c_{k-j}, which is $(\mathbf{C})_{jk}$ by Definition 11.9.1. Hence that matrix is $\mathbf{C} = \Psi(a)$.

(c) By (a) and Theorem 11.9.4, $\mathbf{F}^*\Psi(a)\mathbf{F} = \operatorname{diag}(p_{\mathbf{c}}(1), \dots, p_{\mathbf{c}}(\omega^{n-1}))$, and $p_{\mathbf{c}}(\omega^j) = \Phi(a)(\chi_j)$ was computed at the end of the proof of Theorem 22.9.7.

■

Warning. Part (b) reverses the basis, and the reversal is not cosmetic. With Chapter 11's convention $(\mathbf{C})_{jk} = c_{k-j}$, applying a circulant to a vector is **not** convolution: $(\mathbf{C}\mathbf{x})_j = \sum_t c_t x_{j+t}$, with a plus sign, whereas $(\mathbf{c} * \mathbf{x})_j = \sum_t c_t x_{j-t}$. What is true is that $\mathbf{C}\mathbf{x} = \mathbf{c}^- * \mathbf{x}$, where $\mathbf{c}^-$ is the vector with $(\mathbf{c}^-)_t = c_{-t}$, and that the **product** of two circulants is the circulant of the convolution of their first rows (Theorem 11.9.6 (a)). The group algebra sees the product, which is why Theorem 22.9.8 (a) needs no reversal while (b) does. If you keep only one of these, keep the product statement.

Example. (The case $n = 4$, checked against Chapter 11)

For $G = \mathbb{Z}/4\mathbb{Z}$, write down the character table, the character matrix, and the image under Φ of the element $a = \delta_{[0]} + 2\delta_{[1]} + 3\delta_{[2]} + 4\delta_{[3]}$. Compare with Chapter 11 Section 9.

Solution. Here $\omega = e^{2\pi i/4} = i$ and $\chi_j([m]) = i^{jm}$. The table of values, rows $\chi_0, \chi_1, \chi_2, \chi_3$ and columns $[0], [1], [2], [3]$, is

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & i & -1 & -i \\ 1 & -1 & 1 & -1 \\ 1 & -i & -1 & i \end{pmatrix}.$$

The array is symmetric, since $i^{jm} = i^{mj}$, so reading it with rows indexed by m and

columns by j and dividing by $\sqrt{4} = 2$ gives the character matrix

$$\mathbf{U} = \frac{1}{2}\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & i & -1 & -i \\ 1 & -1 & 1 & -1 \\ 1 & -i & -1 & i \end{pmatrix}.$$

This is exactly the matrix $\mathbf{F}$ of Example (The Fourier matrix of size four).

By Theorem 22.9.8 (a), $\Psi(a)$ is the circulant with first row $(1, 2, 3, 4)$, the running example of Chapter 11 Section 9. By Theorem 22.9.7,

$$\begin{aligned} \Phi(a)(\chi_0) &= 1 + 2 + 3 + 4 = 10, \\ \Phi(a)(\chi_1) &= 1 + 2i - 3 - 4i = -2 - 2i, \\ \Phi(a)(\chi_2) &= 1 - 2 + 3 - 4 = -2, \\ \Phi(a)(\chi_3) &= 1 - 2i - 3 + 4i = -2 + 2i, \end{aligned}$$

using $i^2 = -1$ and $i^3 = -i$. These are the four eigenvalues found in Example (The running example, diagonalized), in the same order, and Theorem 22.9.8 (c) says that $\mathbf{F}^*\Psi(a)\mathbf{F} = \operatorname{diag}(10, -2 - 2i, -2, -2 + 2i)$, which is what that example computed. As a check on the first value, χ_0 is the trivial character, so $\Phi(a)(\chi_0)$ is the sum of the coefficients, which is the common row sum 10 of the circulant.

What has been bought? Chapter 11 said that a circulant is a polynomial in the shift, and proved it with an induction on the entries of $\mathbf{S}^m$. That statement is now structural: $\mathbb{C}[\mathbb{Z}/n\mathbb{Z}]$ is generated as an algebra by one element $\delta_{[1]}$, whose image is $\mathbf{S}$, so *every* element of the algebra is a polynomial in $\mathbf{S}$. What the structural reading does not hand over free is that those polynomials are exactly the circulants; that is still Chapter 11's entry computation (Theorem 11.9.1 (a)), quoted in the proof of Theorem 22.9.8 (a). The one matrix $\mathbf{F}$ that diagonalizes every circulant simultaneously is the character matrix, which exists before any circulant is named because the characters of G exist before any element of $\mathbb{C}[G]$ is named. And the reason the eigenvalues came out as n evaluations of one polynomial is that they are the n coordinates of a in the product decomposition $\mathbb{C}[G] \cong \mathbb{C}^{\widehat{G}}$.

22.9.5 Exercises

22.9.5.1 A. Check your understanding

Exercise A1.

(a) Define the dual group $\widehat{G}$ of a finite abelian group G, and say what its identity and inverses are.

(b) State why $|\widehat{G}| = |G|$, naming the two results used.

(c) Write down the character matrix of G and state what its unitarity says about the characters.

(d) Determine whether the following are true, with a reason. (i) Every irreducible complex representation of a finite abelian group is one-dimensional. (ii) The book has proved $\widehat{G} \cong G$ for every finite abelian G. (iii) The Fourier matrix of Chapter 11 Section 9 is the character matrix of $\mathbb{Z}/n\mathbb{Z}$. (iv) For $\mathbf{A} \in \mathcal{C}_n$ and $\mathbf{x} \in \mathbb{C}^n$, $\mathbf{Ax}$ is

the convolution of the first row of $\mathbf{A}$ with $\mathbf{x}$.

(e) Explain in one sentence why the values of a character of a finite abelian group are roots of unity.

Solution.

(a) $\widehat{G}$ is the set of group homomorphisms $G \to \mathbb{C}^\times$ with the pointwise product (Definition 22.9.3). Its identity is the trivial character $\chi_0 \equiv 1$, and the inverse of χ is $\overline{\chi}$ (Proposition 22.9.2).

(b) Because G is abelian, each conjugacy class is a single element, so there are $|G|$ classes; Theorem 22.8.9 makes the number of irreducible characters equal to that, and Theorem 22.9.1 identifies the irreducible characters with the elements of $\widehat{G}$ (Proposition 22.9.3).

(c) $(\mathbf{U})_{mj} = \chi_j(g_m)/\sqrt{n}$ for fixed orderings of G and $\widehat{G}$ (Definition 22.9.4). Unitarity says the columns are orthonormal, that is, $\frac{1}{n}\sum_g \chi_j(g)\overline{\chi_k(g)} = \delta_{jk}$: the characters are an orthonormal basis of the functions on G (Theorem 22.9.5).

(d) (i) True over $\mathbb{C}$, by Theorem 22.9.1 (a); it is false over $\mathbb{R}$. (ii) False. It is proved here only for direct products of cyclic groups (Theorem 22.9.4), and the book does not prove that every finite abelian group is such a product. (iii) True, entry for entry (Theorem 22.9.6). (iv) False: $(\mathbf{A}\mathbf{x})_j = \sum_t c_t x_{j+t}$, while convolution has x_{j-t}. The product of two circulants, however, is the circulant of the convolution.

(e) Each g has finite order m (Lemma 22.8.1), and applying χ to $g^m = e$ gives $\chi(g)^m = 1$.

22.9.5.2 B. Practice

Exercise B1: The character table of the group of order three.

Let $G = \mathbb{Z}/3\mathbb{Z}$ and $\omega = e^{2\pi i/3}$.

(a) Write down the three characters and the character matrix.

(b) Verify one off-diagonal orthogonality relation by hand.

(c) Let $a = 2\delta_{[0]} - \delta_{[1]} - \delta_{[2]} \in \mathbb{C}[G]$. Compute $\Phi(a)$, write down the circulant $\Psi(a)$, and state its eigenvalues.

Solution.

(a) By Example (The characters of a cyclic group), $\chi_j([m]) = \omega^{jm}$ for $j = 0, 1, 2$, and

$$\mathbf{U} = \frac{1}{\sqrt{3}}\begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \\ 1 & \omega^2 & \omega^4 \end{pmatrix} = \frac{1}{\sqrt{3}}\begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \\ 1 & \omega^2 & \omega \end{pmatrix},$$

using $\omega^4 = \omega^3\omega = \omega$.

(b) Take $j = 1$, $k = 0$. Then

$$\tfrac{1}{3}\sum_{m=0}^{2} \chi_1([m])\overline{\chi_0([m])} = \tfrac{1}{3}(1 + \omega + \omega^2) = 0,$$

since $\omega \neq 1$ and $(\omega - 1)(1 + \omega + \omega^2) = \omega^3 - 1 = 0$.

(c) Here $\mathbf{c} = (2, -1, -1)$, so $\Phi(a)(\chi_j) = 2 - \omega^j - \omega^{2j}$. For $j = 0$ this is $2-1-1 = 0$. For $j = 1$ and $j = 2$ the two subtracted terms are ω and ω^2 in one order or the other, and $\omega + \omega^2 = -1$ by (b), so the value is $2 + 1 = 3$ both times. By Theorem 22.9.8 (a),

$$\Psi(a) = \begin{pmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{pmatrix},$$

with eigenvalues $0, 3, 3$. The eigenvalue 0 is visible directly: every row sums to 0, so the all-ones vector is in the kernel.

Exercise B2: A product of two cyclic groups.

Let $G = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ and $\omega = e^{2\pi i/3}$.

(a) Use Theorem 22.9.4 (b) to list the six characters of G explicitly.

(b) Show that G is cyclic by exhibiting a generator, and say which character of G corresponds to which character of $\mathbb{Z}/6\mathbb{Z}$ under your isomorphism.

Solution.

(a) By Theorem 22.9.4 (b) every character of G is $(x, y) \mapsto \chi(x)\psi(y)$ with $\chi \in \widehat{\mathbb{Z}/2\mathbb{Z}}$ and $\psi \in \widehat{\mathbb{Z}/3\mathbb{Z}}$. By Example (The characters of a cyclic group) these are $\chi_a(x) = (-1)^{ax}$ for $a \in \{0, 1\}$ and $\psi_b(y) = \omega^{by}$ for $b \in \{0, 1, 2\}$. So the six characters are

$$\theta_{a,b}(x, y) = (-1)^{ax}\omega^{by} \qquad (a \in \{0, 1\},\ b \in \{0, 1, 2\}),$$

and there are $2 \cdot 3 = 6 = |G|$ of them, as Proposition 22.9.3 requires.

(b) Let $g = ([1], [1])$. Its multiples are $([1], [1]), ([0], [2]), ([1], [0]), ([0], [1]), ([1], [2]), ([0], [0])$ for $k = 1, \ldots, 6$, all six distinct, so g has order 6 and $G = \langle g \rangle$ is cyclic. Send $[k] \in \mathbb{Z}/6\mathbb{Z}$ to kg; this is the isomorphism. Under it the character χ_j of $\mathbb{Z}/6\mathbb{Z}$ with $\chi_j([k]) = \zeta^{jk}$, $\zeta = e^{2\pi i/6}$, pulls back to $\theta_{a,b}$ with $\theta_{a,b}(g) = (-1)^a\omega^b = \zeta^{3a+2b}$, so $j \equiv 3a+2b \pmod 6$. As (a, b) runs over the six pairs, $3a+2b$ runs over $0, 2, 4, 3, 5, 1$ modulo 6, hitting each residue once.

Exercise B3: A transform and its inversion.

Let $G = \mathbb{Z}/4\mathbb{Z}$ and let f be the function with values $f([0]), f([1]), f([2]), f([3]) = 1, 1, -1, -1$.

(a) Compute $\widehat{f}(\chi_j)$ for $j = 0, 1, 2, 3$.

(b) Recover $f([1])$ from Theorem 22.9.5 (b).

(c) Check Plancherel's identity for f.

Solution.

(a) With $\chi_j([m]) = i^{jm}$ and Definition 22.9.5,

$$\begin{aligned}\widehat{f}(\chi_0) &= 1+1-1-1 = 0,\\ \widehat{f}(\chi_1) &= 1+i-(-1)-(-i) = 2+2i,\\ \widehat{f}(\chi_2) &= 1-1-1+1 = 0,\\ \widehat{f}(\chi_3) &= 1-i+1-i = 2-2i.\end{aligned}$$

For $j=3$ the powers are $i^0, i^3, i^6, i^9 = 1, -i, -1, i$, so the sum is $1-i+1-i$.

(b) Only $j = 1, 3$ contribute, and $\overline{\chi_1([1])} = \overline{i} = -i$, $\overline{\chi_3([1])} = \overline{-i} = i$. So

$$\tfrac{1}{4}\big((2+2i)(-i) + (2-2i)(i)\big) = \tfrac{1}{4}\big((2-2i)+(2+2i)\big) = 1,$$

using $(2+2i)(-i) = -2i - 2i^2 = 2-2i$ and $(2-2i)(i) = 2i - 2i^2 = 2+2i$. This is $f([1])$, as it should be.

(c) The left side is $1+1+1+1 = 4$. The right side is $\frac{1}{4}(0 + |2+2i|^2 + 0 + |2-2i|^2) = \frac{1}{4}(8+8) = 4$. They agree.

22.9.5.3 C. Going deeper

Exercise C1: The idempotents that do the splitting.

Let G be a finite abelian group of order n. For $\chi \in \widehat{G}$ put

$$\varepsilon_\chi := \frac{1}{n}\sum_{g\in G} \overline{\chi(g)}\,\delta_g \in \mathbb{C}[G].$$

(a) Prove that $\Phi(\varepsilon_\chi)(\psi)$ equals 1 when $\psi = \chi$ and 0 otherwise.

(b) Deduce that $\varepsilon_\chi \varepsilon_\psi = 0$ for $\chi \neq \psi$, that $\varepsilon_\chi^2 = \varepsilon_\chi$, and that $\sum_\chi \varepsilon_\chi = \delta_e$.

(c) For $G = \mathbb{Z}/4\mathbb{Z}$ write ε_{χ_1} out, and identify the matrix $\Psi(\varepsilon_{\chi_1})$ in terms of the Fourier vector $\mathbf{f}_1$ of Chapter 11 Section 9.

Hint for (a): the sum is an inner product of two characters.

Solution.

(a) By Definition 22.9.5 and the definition of Φ,

$$\Phi(\varepsilon_\chi)(\psi) = \frac{1}{n}\sum_g \overline{\chi(g)}\,\psi(g) = \frac{1}{n}\sum_g \psi(g)\overline{\chi(g)},$$

which is the inner product of the irreducible characters ψ and χ (Definition 22.8.4). By Theorem 22.8.7 it is 1 if $\psi = \chi$ and 0 otherwise.

(b) Φ is an isomorphism of algebras (Theorem 22.9.7), and in $\mathbb{C}^{\widehat{G}}$ the functions $\Phi(\varepsilon_\chi)$ are the point masses at the various χ. Point masses satisfy exactly the three relations claimed: the pointwise product of two distinct ones is 0, each is its own square, and their sum is the constant function 1, which is $\Phi(\delta_e)$. Applying Φ^{-1} transfers the relations to $\mathbb{C}[G]$.

(c) With $\chi_1([m]) = i^m$, $\overline{\chi_1([m])} = (-i)^m$, so

$$\varepsilon_{\chi_1} = \tfrac{1}{4}\big(\delta_{[0]} - i\,\delta_{[1]} - \delta_{[2]} + i\,\delta_{[3]}\big).$$

By Theorem 22.9.8 (a), $\Psi(\varepsilon_{\chi_1})$ is the circulant with first row $\frac{1}{4}(1,-i,-1,i)$, whose (j,k)-entry is $\frac{1}{4}(-i)^{k-j} = \frac{1}{4}i^{j-k}$. With $\mathbf{f}_1 = \frac{1}{2}(1,i,-1,-i)$, the matrix $\mathbf{f}_1\mathbf{f}_1^*$ has (j,k)-entry $\frac{1}{4}i^j\overline{i^k} = \frac{1}{4}i^{j-k}$. This ε_{χ_1} is the idempotent called e_2 in Example (The group algebra of a cyclic group of order four), whose list runs from 1 and is written in the generator $g = [1]$. So $\Psi(\varepsilon_{\chi_1}) = \mathbf{f}_1\mathbf{f}_1^*$, the orthogonal projection onto the line spanned by $\mathbf{f}_1$. The idempotents of the group algebra are the spectral projections of Chapter 11.

Exercise C2: The double dual needs no choices.

Let G be a finite abelian group. For $g \in G$ define $\mathrm{ev}_g \colon \widehat{G} \to \mathbb{C}^\times$ by $\mathrm{ev}_g(\chi) \coloneqq \chi(g)$.

(a) Prove that $\mathrm{ev}_g \in \widehat{\widehat{G}}$ and that $g \mapsto \mathrm{ev}_g$ is a group homomorphism $G \to \widehat{\widehat{G}}$.

(b) Prove that it is injective. *Hint: the rows of the character matrix are indexed by the elements of G.*

(c) Deduce that it is an isomorphism, and explain why this is not a second proof of Theorem 22.9.4.

Solution.

(a) For $\chi, \psi \in \widehat{G}$, $\mathrm{ev}_g(\chi\psi) = (\chi\psi)(g) = \chi(g)\psi(g) = \mathrm{ev}_g(\chi)\,\mathrm{ev}_g(\psi)$, so ev_g is a homomorphism $\widehat{G} \to \mathbb{C}^\times$, that is an element of $\widehat{\widehat{G}}$. And $\mathrm{ev}_{gh}(\chi) = \chi(gh) = \chi(g)\chi(h) = (\mathrm{ev}_g\,\mathrm{ev}_h)(\chi)$, so $g \mapsto \mathrm{ev}_g$ is a homomorphism.

(b) Suppose ev_g is the trivial character of $\widehat{G}$, that is $\chi(g) = 1 = \chi(e)$ for every $\chi \in \widehat{G}$. Then the rows of the character matrix indexed by g and by e are equal, so $\mathbf{U}$ has two equal rows and is singular, contradicting Theorem 22.9.5 (a) unless $g = e$. Hence the kernel is trivial and the map is injective (Theorem 0.10.3 gives that the kernel is a subgroup, and a homomorphism with trivial kernel is injective by cancellation).

(c) By Proposition 22.9.3 applied twice, $|\widehat{\widehat{G}}| = |\widehat{G}| = |G|$, so an injective homomorphism between them is a bijection, hence an isomorphism. It is not a proof that $\widehat{G} \cong G$: it compares G with the dual of its dual, and gives no map between G and $\widehat{G}$ at all. The difference is exactly the one Chapter 4 drew between $V \cong V^*$, which needs a choice of basis, and $V \cong V^{**}$, which does not.

Exercise C3: The same theory over a finite field.

Two properties of $\mathbb{C}$ were in use throughout this section: it contains n distinct n-th roots of unity, and n is invertible in it. They are not everything $\mathbb{C}$ contributed: algebraic closure was spent in Theorem 22.9.1 (a), and Section 8's orthogonality relations were proved for complex representations only. But for one group and one field the conclusions can be checked directly with nothing more than those two properties. Take $F = \mathbb{F}_5$, $G = \mathbb{Z}/4\mathbb{Z}$ and $\omega = 2 \in \mathbb{F}_5$.

(a) Verify that ω has order 4 in $\mathbb{F}_5^\times$, and that 4 is invertible in $\mathbb{F}_5$.

(b) Write down the 4×4 matrix $\mathbf{M}$ with $(\mathbf{M})_{mj} = \omega^{jm}$ over $\mathbb{F}_5$ and check that $4^{-1}\sum_m \omega^{jm}\omega^{-km} = \delta_{jk}$ for $j = 1$ and $k = 0, 1$.

(c) Let $\mathbf{C}$ be the circulant over $\mathbb{F}_5$ with first row $(1, 2, 3, 4)$. Compute $\mathbf{M}^{-1}\mathbf{C}\mathbf{M}$ without inverting $\mathbf{M}$, by evaluating the symbol at the powers of ω.

Hint for (c): the proof of Theorem 11.9.4 used only $\mathbf{S}^n = \mathbf{I}$ and the geometric-series identity, both of which hold over $\mathbb{F}_5$.

Solution.

(a) $2^1 = 2$, $2^2 = 4$, $2^3 = 3$, $2^4 = 1$ in $\mathbb{F}_5$, so $\omega = 2$ has order 4 and $1, 2, 4, 3$ are four distinct fourth roots of 1. Also $4 \cdot 4 = 16 = 1$, so 4 is invertible with $4^{-1} = 4$. Note $\operatorname{char}\mathbb{F}_5 = 5$ does not divide $|G| = 4$, which is Maschke's hypothesis.

(b) Reading rows $m = 0, 1, 2, 3$ and columns $j = 0, 1, 2, 3$,

$$\mathbf{M} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 4 & 3 \\ 1 & 4 & 1 & 4 \\ 1 & 3 & 4 & 2 \end{pmatrix}.$$

For $j = k = 1$ every term is $\omega^m\omega^{-m} = 1$, so the sum is $4^{-1} \cdot 4 = 1$. For $j = 1$, $k = 0$ it is $4^{-1}(1 + 2 + 4 + 3) = 4 \cdot 10 = 4 \cdot 0 = 0$ in $\mathbb{F}_5$.

(c) The symbol is $p_{\mathbf{c}}(x) = 1 + 2x + 3x^2 + 4x^3$. Evaluating over $\mathbb{F}_5$:

$$\begin{aligned} p_{\mathbf{c}}(1) &= 1 + 2 + 3 + 4 = 10 = 0, \\ p_{\mathbf{c}}(2) &= 1 + 4 + 12 + 32 = 49 = 4, \\ p_{\mathbf{c}}(4) &= 1 + 8 + 48 + 256 = 313 = 3, \\ p_{\mathbf{c}}(3) &= 1 + 6 + 27 + 108 = 142 = 2. \end{aligned}$$

The columns of $\mathbf{M}$ are the eigenvectors, so $\mathbf{M}^{-1}\mathbf{C}\mathbf{M} = \operatorname{diag}(0, 4, 3, 2)$. The matrix $\mathbf{C}$ is singular over $\mathbb{F}_5$, as it must be: its row sums are $10 = 0$. Every conclusion checked here holds over $\mathbb{F}_5$ for this G, except that "unitary" has no meaning and $\mathbf{M}$ is merely invertible; the orthogonality relations survive with $\overline{\cdot}$ replaced by inversion in $\mathbb{F}_5^\times$.

22.10 What the Chapter Buys

Nine sections is a lot of new vocabulary, and vocabulary is not what you should carry away. This closing section introduces nothing. It names the four moves the chapter actually used, reads four earlier theorems of the book again from the height we have reached, sets out in one place which hypothesis on the field each result needed and what breaks without it, and says plainly what was quoted rather than proved and what was left outside the door on purpose.

22.10.1 Four moves

Average over the group to build an invariant object. This is the whole of Theorem 22.7.3. Given a projection onto a subrepresentation that is not invariant, replace it by the average of its conjugates $\rho(g)P\rho(g)^{-1}$ over $g \in G$; the average is invariant because translating the summation index permutes the summands, and it is still a projection onto the same subspace. The hypothesis $\operatorname{char} F \nmid |G|$ is not decoration: the average is divided by $|G|$, and if that number is 0 in F there is nothing to divide by. The same move produced the intertwiner in Theorem 22.8.7, where an arbitrary linear map is averaged into an equivariant one.

Once you have seen it, you will recognize it elsewhere: whenever a construction depends on a choice and a finite group acts on the choices, averaging over the group removes the dependence.

Use Schur's lemma to force a scalar. Theorem 22.4.1 has two halves, and the useful one in practice is the second: over an algebraically closed field, an operator commuting with an irreducible family is a scalar (Corollary 22.4.3). The pattern of use is always the same. You have an operator built by some construction, you check it commutes with everything in sight, and you conclude it is λ id; then you take a trace to find λ. That single step is what turns the averaged intertwiner of the previous paragraph into the orthogonality relations, and it is what collapses the representations of an abelian group to lines (Corollary 22.4.4).

Count with $\sum n_i^2$. Wedderburn's theorem gives $\dim A = \sum_i n_i^2$ (Corollary 22.6.2), which for a group algebra reads $|G| = \sum_i (\dim V_i)^2$ (Corollary 22.8.10). This is a very strong constraint for a small group: once you know the number of conjugacy classes, the sum of squares often has only one solution, and you have the dimensions of all the irreducible representations before you have written down a single matrix. It plays the role Rank–Nullity plays in Chapter 3: an identity that pins down what you were otherwise going to have to compute.

Read a commuting family as a commutative algebra. Chapters 8 and 11 studied families $\mathcal{F} \subseteq \mathcal{L}(V)$ whose members commute. The algebra generated by $\mathcal{F}$ is then commutative, and the chapter's theorems apply to it directly. This is not a reformulation for its own sake; it is what makes the next four paragraphs possible.

22.10.2 Four old theorems, seen from here

Commuting operators have a common eigenvector (Theorem 8.9.3). Chapter 8 proved this by restricting to an eigenspace and inducting. From here: the algebra A generated by the family is commutative, and V contains an irreducible A-invariant subspace U, namely a non-zero invariant subspace of least dimension. By Corollary 22.4.4, over an algebraically closed field U is a line, and a line invariant under every member of the family is precisely a common eigenvector. Chapter 8's hypothesis — that each characteristic polynomial splits — is what algebraic closure was standing in for. Theorem 8.9.5 then follows by decomposing V into such lines.

One orthonormal eigenbasis for a commuting normal family (Theorem 11.7.1). The same statement with the inner product carried along. The commuting normal family generates a commutative algebra, and that algebra is closed under adjoints because the adjoint of a normal operator is a polynomial in it (Corollary 11.4.5). Closure under adjoints is exactly what makes the invariant complement available without averaging: the orthogonal complement of an invariant subspace is invariant (Proposition 22.4.6). So the family acts semisimply for free, and over $\mathbb{C}$ — where Corollary 22.4.4 applies — the decomposition into lines is orthogonal.

Circulants and the discrete Fourier transform (Theorem 11.9.4, Corollary 11.9.5, Theorem 11.9.6). Section 9 did this one in full. Chapter 11 found a single unitary $\mathbf{F}$ diagonalizing every circulant at once and could not say where it came from; it came from the character table of $\mathbb{Z}/n\mathbb{Z}$ (Theorem 22.9.6). Chapter 11 found that the product of two circulants is the circulant of the convolution of their first rows; that is multiplication in the group algebra written in the wrong basis, and in the right one it is the coordinatewise product on $\mathbb{C}^{\widehat{G}}$ (Theorem 22.9.7). Chapter 11 found that every circulant is a polynomial in the shift; that is the statement that $\mathbb{C}[\mathbb{Z}/n\mathbb{Z}]$ is generated by one element (Theorem 22.9.8). Three computations, one structure.

The commutant of a Weyr matrix (Proposition 9.4.6), **and disjoint spectra splitting a commutant** (Corollary 11.10.4). These were computations with blocks. The chapter's name for what they compute is the commutant A' of the algebra A generated by the matrix, and Theorem 22.5.5 says what to expect of it when A is semisimple: the commutant of the commutant gives nothing new. Chapter 11's disjoint-spectra result is the case where the invariant subspaces are forced apart by the spectra alone, semisimple or not, so that the answer is block diagonal whatever the blocks are like inside; Chapter 9's Weyr computation is the opposite situation, one eigenvalue and a matrix that need not be semisimple, where the double commutant theorem does not apply and the answer is correspondingly untidy — block triangular rather than block diagonal.

> *Quick check.* Chapter 11 proved that the Fourier matrix is unitary by summing a geometric series. Section 8 proved the same relations by averaging and Schur's lemma. What does the second proof need that the first does not?

> *Solution.* The second needs the field to be $\mathbb{C}$ — algebraically closed, so that Schur's lemma gives scalars, and of characteristic not dividing $|G|$, so that the averaging is legal — and it needs the group to be finite. The first needs only the identity $(z-1)(1+z+\cdots+z^{n-1}) = z^n - 1$, and it works over any field containing n distinct n-th roots of unity, as Exercise (C3: The same theory over a finite field) shows over $\mathbb{F}_5$. The second proof explains; the first computes. Neither replaces the other.

22.10.3 Which hypothesis did what

Almost every theorem in this chapter is false over the wrong field, and the table is worth having in one place. In it F is the field of the representation and G is a finite group.

Result	Needs	What fails without it
Theorem 22.2.2	nothing	—
Theorem 22.4.1, first half	nothing	—
Theorem 22.4.1, second half	F algebraically closed	the rotation representation of a cyclic group on $\mathbb{R}^2$ is irreducible with commutant a copy of $\mathbb{C}$
Corollary 22.4.4	F algebraically closed	the same rotation representation, irreducible of dimension 2
Corollary 22.4.5	F algebraically closed	the same rotation matrix, a commuting family of one member with no real eigenvector

Result	Needs	What fails without it
Theorem 22.5.2	F algebraically closed	the same example: a proper subalgebra acting irreducibly
Theorem 22.6.1, as proved here	F algebraically closed, A semisimple	without closure, $\mathbb{C}$ as an $\mathbb{R}$-algebra is semisimple and is not a product of matrix algebras over $\mathbb{R}$; without semisimplicity, the upper triangular matrices are not one either
Theorem 22.5.5	no field hypothesis; A acts semisimply and contains id_V	for the upper triangular 2×2 matrices, A' is the scalars and $A'' = M_2(F) \neq A$
Theorem 22.7.3	$\mathrm{char}\, F \nmid \lvert G\rvert$	$\mathbb{Z}/p\mathbb{Z}$ acting on $\mathbb{F}_p^2$ by unipotent matrices: the invariant line has no invariant complement
Theorem 22.8.7	$F = \mathbb{C}$	the modular case, which the chapter does not treat
Theorem 22.9.1	$F = \mathbb{C}$	over $\mathbb{R}$ the group $\mathbb{Z}/3\mathbb{Z}$ has only the trivial character

Three comments on the table. First, Theorem 22.5.5 is the one big theorem of the chapter that needs nothing of the field at all; what it needs is semisimplicity, and that is a hypothesis about the algebra and the space it acts on. Second, the two "algebraically closed" rows about Schur and Burnside are the same failure seen twice, and the witness is the same rotation matrix both times; that is a sign the hypothesis is doing genuine work rather than covering a gap in a proof. Third, the characteristic hypothesis and the algebraic-closure hypothesis are independent. Over $\mathbb{C}$ only the first can fail, and it cannot, since $\mathrm{char}\, \mathbb{C} = 0$; that is why the complex theory is so much cleaner than the general one, and why the chapter chose $\mathbb{C}$ whenever it could.

> *Warning.* The most tempting misreading of this chapter is "every finite-dimensional algebra over $\mathbb{C}$ is a product of matrix algebras". It is not. Theorem 22.6.1 assumes the algebra is **semisimple**, and the upper triangular 2×2 matrices over $\mathbb{C}$ are a three-dimensional algebra that is not. Acting on $\mathbb{C}^2$, that algebra leaves the line $\mathrm{span}(\mathbf{e}_1)$ invariant with no invariant complement, since $\mathbf{E}_{12}$ sends any $(x, 1)$ to $(1, 0)$; and its radical is the line spanned by $\mathbf{E}_{12}$ (Definition 22.3.5). No product of matrix algebras has a non-zero radical. Before applying Wedderburn, check semisimplicity — and for a group algebra that check is Theorem 22.7.3, which is a statement about the characteristic and nothing else.

22.10.4 Quoted, not proved

The chapter stated six things with credit and proved none of them. Nothing in the chapter rests on any of them, and each is flagged where it appears.

- **Wedderburn–Artin over a division ring.** A finite-dimensional semisimple algebra over any field is a product of matrix algebras over division rings. We proved only the algebraically closed case, where the division rings are the field itself. The book has not

built division rings, and the general theorem needs them.

- **Wedderburn's little theorem**, that a finite division ring is a field. Same reason.
- **The character table does not determine the group.** There are two non-isomorphic groups of order 8 with identical character tables. The book has neither the group theory to construct them nor the need.
- **The structure theorem for finite abelian groups**, that every one is a direct product of cyclic groups. Section 9 proved $\widehat{G} \cong G$ only for such products, and said so. Chapter 9's Smith normal form is the linear-algebra shadow of the missing argument.
- **The converse of Proposition 22.3.6**, that a finite-dimensional algebra with zero radical is semisimple. Section 3 states it and does not use it; wherever semisimplicity is needed later it is established directly.
- **When the commutant of a single matrix is the algebra of polynomials in it**, namely when the minimal and characteristic polynomials agree. Section 1 states the criterion in a remark and computes examples on both sides of it, and proves nothing about it.

22.10.5 Left outside on purpose

The subject continues, and the chapter stopped where the book's tools stopped rather than where the subject does. Four directions, in rough order of how soon you would meet them.

Induced representations and Frobenius reciprocity. Given a subgroup $H \leq G$ and a representation of H, there is a way to build a representation of G, and the characters of the two are related by an adjunction. This is the standard next tool, and it is the standard way to produce the irreducible representations of a group rather than merely count them. It needs cosets of a subgroup, which Chapter 0 does not have.

Modular representation theory. What happens when $\operatorname{char} F$ divides $|G|$ and Theorem 22.7.3 fails. Representations no longer decompose into irreducibles, the group algebra is not semisimple, and a genuinely different theory takes over. Section 7's unipotent example is the whole of what we said about it.

Character tables as a computational subject. We computed a few small ones: the symmetric group on three letters, the cyclic group $\mathbb{Z}/n\mathbb{Z}$, and the Klein four-group. Computing them in general is a craft with its own techniques, and it belongs to a course on group theory.

Representations of infinite groups. Every theorem here used finiteness twice: to average, and to count. For compact groups an integral replaces the sum and most of the chapter survives; for other infinite groups almost none of it does.

22.10.6 One more look back

The book began with one linear map and asked for a basis making it simple. Chapter 8 found eigenvectors, Chapter 9 found the Jordan and rational forms, Chapters 10 to 12 found orthonormal bases when there was an inner product to respect. Then the question widened: Chapter 8 Section 9 and Chapter 11 Section 7 asked for a basis good for a whole commuting family at once. This chapter widened it once more, to a set of operators closed under composition, and found that over an algebraically closed field there is essentially one building block, a full matrix algebra, and that everything semisimple is a product of those.

That is a satisfying place to stop, but notice what it cost. The answer is clean only over an algebraically closed field, only for semisimple algebras, and — on the group side — only when the characteristic is coprime to the order. Every one of those three conditions was a real restriction with a two-by-two counterexample behind it. A structure theorem that applies to everything is usually a structure theorem that says nothing; this one says a great deal, and the price is printed on the label.

22.10.7 Exercises

22.10.7.1 A. Check your understanding

Exercise A1.

(a) Name the four moves of this chapter and, for each, one theorem in which it was used.

(b) State the field hypothesis needed by each of Theorem 22.4.1 (second half), Theorem 22.5.2, Theorem 22.6.1 and Theorem 22.7.3.

(c) Determine whether the following are true, with a reason. (i) Every finite-dimensional complex algebra is a product of matrix algebras. (ii) Every complex representation of a finite group decomposes into irreducibles. (iii) Every representation of a finite group over every field decomposes into irreducibles. (iv) The book proves that two non-isomorphic groups can share a character table.

(d) Why is $|G| = \sum_i (\dim V_i)^2$ useful before any matrix has been written down?

Solution.

(a) Averaging over the group, used in Theorem 22.7.3 and Theorem 22.8.7; forcing a scalar with Schur, used in Corollary 22.4.3 and Corollary 22.4.4; counting with $\sum n_i^2$, used in Corollary 22.6.2 and Corollary 22.8.10; reading a commuting family as a commutative algebra, used throughout Section 9 and in the rereading of Theorem 8.9.5 above.

(b) Schur's second half and Burnside both need F algebraically closed. Theorem 22.6.1, in the form proved here, needs F algebraically closed and the algebra semisimple. Theorem 22.7.3 needs $\operatorname{char} F \nmid |G|$ and nothing else.

(c) (i) False: the upper triangular 2×2 matrices are a counterexample, since they are not semisimple. (ii) True, by Corollary 22.7.4, since $\operatorname{char} \mathbb{C} = 0$ never divides $|G|$. (iii) False: $\mathbb{Z}/p\mathbb{Z}$ on $\mathbb{F}_p^2$ by unipotent matrices. (iv) False. The statement is quoted with credit and not proved.

(d) Because the number of summands is the number of conjugacy classes (Theorem 22.8.9), and for a small group the equation $|G| = \sum n_i^2$ with that many positive integer summands, one of which is 1 for the trivial representation, usually has a unique solution. The dimensions come out of arithmetic rather than out of linear algebra.

22.10.7.2 B. Practice

Exercise B1: Two group algebras of order six.

(a) Write down the Wedderburn decomposition of $\mathbb{C}[\mathbb{Z}/6\mathbb{Z}]$, with a reason for each factor.

(b) The group S_3 has three conjugacy classes. Use Corollary 22.8.10 to find the dimensions of its irreducible complex representations, and write down the Wedderburn decomposition of $\mathbb{C}[S_3]$.

(c) Check both answers against $\dim \mathbb{C}[G] = |G|$.

Solution.

(a) $\mathbb{Z}/6\mathbb{Z}$ is abelian, so all irreducible representations are one-dimensional (Theorem 22.9.1) and there are six of them (Proposition 22.9.3). Hence

$$\mathbb{C}[\mathbb{Z}/6\mathbb{Z}] \cong \mathbb{C} \times \mathbb{C} \times \mathbb{C} \times \mathbb{C} \times \mathbb{C} \times \mathbb{C},$$

which is Theorem 22.9.7 for this group.

(b) Three conjugacy classes means three irreducible representations (Theorem 22.8.9), of dimensions $n_1, n_2, n_3 \geq 1$ with $n_1^2 + n_2^2 + n_3^2 = 6$ by Corollary 22.8.10. The only solution in positive integers, up to order, is $1 + 1 + 4$, so the dimensions are $1, 1, 2$. Therefore

$$\mathbb{C}[S_3] \cong \mathbb{C} \times \mathbb{C} \times M_2(\mathbb{C}).$$

(c) In (a), $6 \cdot 1 = 6$. In (b), $1 + 1 + 4 = 6$. Both match $\dim \mathbb{C}[G] = |G|$, which is the dimension count of Corollary 22.6.2.

Exercise B2: What the sum of squares allows at order eight.

Let G be a group of order 8.

(a) List all the possible multisets of dimensions of the irreducible complex representations of G. *Remember that the trivial representation is always present.*

(b) Say which of your lists corresponds to an abelian G, and why.

(c) Deduce how many conjugacy classes a non-abelian group of order 8 has.

Solution.

(a) By Corollary 22.8.10 the dimensions satisfy $\sum n_i^2 = 8$ with every $n_i \geq 1$. Let k be the number of n_i equal to 2 or more. Since $3^2 = 9 > 8$, every n_i is 1 or 2, so $8 = 4k +$ (number of ones). For $k = 0$ we get eight 1s; for $k = 1$, four 1s and one 2; for $k = 2$ we would get no 1s at all, which is impossible because the trivial representation has dimension 1. So the two possibilities are $(1, 1, 1, 1, 1, 1, 1, 1)$ and $(1, 1, 1, 1, 2)$.

(b) The first. By Theorem 22.9.1 an abelian G has all irreducible representations one-dimensional, and conversely if all dimensions are 1 then by Theorem 22.6.1 the algebra $\mathbb{C}[G]$ is a product of copies of $\mathbb{C}$, hence commutative; since the elements δ_g commute in $\mathbb{C}[G]$, the group is abelian.

(c) A non-abelian G of order 8 has dimension list $(1, 1, 1, 1, 2)$, so five irreducible representations, and by Theorem 22.8.9 five conjugacy classes.

22.10.7.3 C. Going deeper

Exercise C1: The circulants as a semisimple algebra.

Let $n \geq 2$ and let $\mathcal{C}_n \subseteq M_n(\mathbb{C})$ be the algebra of circulants of Chapter 11 Section 9.

(a) Explain why $\mathcal{C}_n$ acts semisimply on $\mathbb{C}^n$, and write down its Wedderburn form as an abstract algebra.

(b) Prove that an $\mathbf{X} \in M_n(\mathbb{C})$ commutes with every circulant if and only if $\mathbf{F}^*\mathbf{X}\mathbf{F}$ is diagonal, and deduce $\mathcal{C}_n' = \mathcal{C}_n$.

(c) Verify Theorem 22.5.5 for $A = \mathcal{C}_n$.

Hint for (b): first show that a matrix commuting with every diagonal matrix is diagonal, by testing against the matrix units $\mathbf{E}_{kk}$.

Solution.

(a) First, $\mathcal{C}_n$ acts semisimply on $\mathbb{C}^n$. By Theorem 11.9.1 (b) the adjoint of a circulant is a circulant, so if U is $\mathcal{C}_n$-invariant and $\mathbf{x} \in U^\perp$, then for every $\mathbf{C} \in \mathcal{C}_n$ and $\mathbf{u} \in U$ we have $\langle \mathbf{C}\mathbf{x}, \mathbf{u}\rangle = \langle \mathbf{x}, \mathbf{C}^*\mathbf{u}\rangle = 0$, because $\mathbf{C}^*\mathbf{u} \in U$; so $U^\perp$ is an invariant complement. Second, as an abstract algebra $\mathcal{C}_n \cong \mathbb{C}[\mathbb{Z}/n\mathbb{Z}]$ by Theorem 22.9.8, and by Theorem 22.9.7 its Wedderburn form is the product of n copies of $\mathbb{C}$; all the blocks of Theorem 22.6.1 are 1×1 because the algebra is commutative.

(b) First the hint. Suppose $\mathbf{Y} \in M_n(\mathbb{C})$ commutes with every diagonal matrix. Taking $\mathbf{D} = \mathbf{E}_{kk}$, the matrix $\mathbf{Y}\mathbf{E}_{kk}$ has k-th column equal to the k-th column of $\mathbf{Y}$ and zeros elsewhere, while $\mathbf{E}_{kk}\mathbf{Y}$ has k-th row equal to the k-th row of $\mathbf{Y}$ and zeros elsewhere. Equating them forces $y_{jk} = 0$ for $j \neq k$ and $y_{kj} = 0$ for $j \neq k$. Letting k run, $\mathbf{Y}$ is diagonal.
Now let $\mathbf{X}$ commute with every circulant and put $\mathbf{Y} = \mathbf{F}^*\mathbf{X}\mathbf{F}$. By Corollary 11.9.5 (c) the circulants are exactly the matrices $\mathbf{F}\mathbf{D}\mathbf{F}^*$ with $\mathbf{D}$ diagonal, and

$$\mathbf{X}(\mathbf{F}\mathbf{D}\mathbf{F}^*) = (\mathbf{F}\mathbf{D}\mathbf{F}^*)\mathbf{X} \iff \mathbf{Y}\mathbf{D} = \mathbf{D}\mathbf{Y},$$

after multiplying by $\mathbf{F}^*$ on the left and $\mathbf{F}$ on the right and using $\mathbf{F}^*\mathbf{F} = \mathbf{I}$ (Theorem 11.9.3). So $\mathbf{X}$ commutes with every circulant exactly when $\mathbf{Y}$ commutes with every diagonal matrix, that is exactly when $\mathbf{Y}$ is diagonal, that is exactly when $\mathbf{X} \in \mathcal{C}_n$. Hence $\mathcal{C}_n' = \mathcal{C}_n$.

(c) By (b), $\mathcal{C}_n'' = (\mathcal{C}_n')' = \mathcal{C}_n' = \mathcal{C}_n$. And $\mathcal{C}_n$ acts semisimply on $\mathbb{C}^n$ by (a) and contains $\mathbf{I}$, so Theorem 22.5.5 applies and predicts exactly this. The example also shows the theorem has content: for the algebra of scalar matrices, which is also semisimple and contains $\mathbf{I}$, the commutant is all of $M_n(\mathbb{C})$ and the double commutant is the scalars again — the same conclusion reached along a very different route.

Chapter 23

Computation and Applications

Chapter 20 closed Part V by naming a debt: "every proof here is an existence or a comparison, and not one of them is an algorithm. That is the subject of Chapter 23." It is the book's largest single debt — twenty-six promises across eighteen files — and it has been accumulating since Chapter 2, where partial pivoting was recommended for a reason the book could not yet give. Twenty chapters have built objects and proved things about them. Not one has said how to produce those objects from data of finite accuracy, in finitely many arithmetic operations, and not one has been able to say what an answer computed that way even means.

This chapter answers three questions in that order. **What does a computed answer mean?** It is the exact answer to a nearby question, and the whole of numerical linear algebra lies in making "nearby" precise: a model of arithmetic, backward error, and the rule that ties the two to Chapter 15's condition number, with Chapter 19's residual bounds supplying the error bars. **How are the objects of this book actually computed?** Elimination with pivoting, least squares by reflections, eigenvalues by iteration — because no finite eigenvalue algorithm can exist — Krylov subspaces, conjugate gradients, the fast Fourier transform and fast multiplication. **What is linear algebra for?** Vibrations, principal components and graphs, each an application in which a theorem already proved does the work.

The chapter is about arithmetic, algorithms and cost. No product, library or language is named anywhere in it: an algorithm here is a rule for producing numbers from numbers, and its cost is a count of arithmetic operations.

23.0.1 Conventions

Seven conventions hold throughout, and each is stated once where it is introduced.

- u **is the unit roundoff** and $\mathrm{fl}(\cdot)$ the rounding map of §01's model, with $\mathcal{R}$ the set of representable numbers and $\gamma_k = ku/(1-ku)$ the accumulated-rounding constant, defined in §01 and used in every section that mentions arithmetic.
- **A flop is one arithmetic operation**, and costs are leading-order counts, written $\frac{2}{3}n^3 + O(n^2)$. The constant matters and the exponent matters more; §§02 and 13 are where that sentence is made quantitative.
- **Perturbations of data are $\Delta\mathbf{A}$ and $\Delta\mathbf{b}$**, and a computed object carries a hat: $\widehat{\mathbf{x}}$, $\widehat{\mathrm{L}}$. Chapters 15, 16 and 19 wrote a perturbation $\mathbf{E}$; $\mathbf{E}$ is kept here for a perturbation whose size is given, and Δ for one produced by an algorithm.

- $\kappa(\mathbf{A})$ **always means Chapter 15 §08's condition number** (Definition 15.8.1). Chapter 19 §11's condition number of a simple eigenvalue does not appear in this chapter, so the two never have to be told apart.
- **Iteration indices are superscripts in parentheses**, $\mathbf{x}^{(k)}$, $\mathbf{A}^{(k)}$, leaving subscripts free for coordinates.
- $|\mathbf{A}|$ **is the entrywise absolute value** ($|a_{ij}|$), as in Chapter 18, and $\mathbf{A} \le \mathbf{B}$ the entrywise order. This is a local override of Chapter 12's $|\mathbf{A}| = (\mathbf{A}^*\mathbf{A})^{1/2}$, which does not appear in this chapter.
- **New symbols**, each defined at its first use: the growth factor g_n (§02), the Krylov space $\mathcal{K}_k(\mathbf{A}, \mathbf{b})$ and the Ritz values (§06), the energy norm $\|\cdot\|_{\mathbf{A}}$ and the Chebyshev polynomials T_k (§07, the same polynomials as Chapter 10 §10), the mass and stiffness matrices $\mathbf{M}$ and $\mathbf{K}$ (§09), the data matrix $\mathbf{X}$ with its centered form $\mathbf{X}_c$ and sample covariance $\mathbf{S}$ (§10), the graph Laplacian and its reduced form (§11, following Chapter 2 §07), the unnormalized Fourier matrix $\mathbf{W}_n = \sqrt{n}\,\mathbf{F}_n$ (§12), and the arithmetic cost $M(n)$ with the exponent ω (§13). Two letters are reused, each with a warning where it happens: Ł is the flowed matrix of §08 and the Laplacian of §11, and $\mathbf{K}$ is §09's stiffness matrix, not Chapter 18 §09's second-difference matrix $\mathbf{K}_n$.

23.0.2 What the chapter assumes

Every earlier chapter assumed only field axioms, and Part V added a short list of facts from analysis. This chapter adds assumptions of a different kind, and both are stated as definitions so that the reader can see exactly where mathematics stops.

Floating-point arithmetic is not a theorem of linear algebra. It is a model of a machine. A machine stores finitely many numbers and rounds every result to one of them, and the statement that it does so with a small relative error is a description of a device, not a fact to be proved. So §01 states it as a **definition**, Definition 23.1.1, in the register this book uses for definitions: a finite set of representable numbers, a rounding map fl, and the requirement

$$\mathrm{fl}(x \odot y) = (x \odot y)(1 + \delta), \qquad |\delta| \le u,$$

for $\odot \in \{+, -, \times, \div\}$ and for the square root, with overflow and underflow excluded by assumption. Everything after §01 is a theorem **about that model**. The model is an idealization: the arithmetic in common use satisfies it for those five operations, with u about 10^{-16}, and every rounding claim in this chapter is a consequence of it and of nothing else.

Section 9 does the same for a piece of physics. Newton's second law and Hooke's law are not theorems either, so Definition 23.9.1 names them as clauses (P1) and (P2), says that Hooke's law holds only for small displacements and that no real system is free of friction, and every statement about vibrations is then a theorem about that idealization. Nothing outside §09 uses it.

No new analysis is imported. The list remains Chapter 15's facts **(A1)–(A6)** — completeness, monotone convergence, compactness of closed bounded sets, the extreme value theorem, the intermediate value theorem and the mean value theorem — together with the algebra of limits. Each is named again where it is used. **Chapter 20's quoted fact (A7), the Nevanlinna–Pick characterization behind Loewner's theorem, is not used anywhere in this chapter**, and neither is any consequence of it that Chapter 20 marked as resting on it.

23.0.3 What is quoted and not proved

Several classical results in this subject have proofs longer than the sections that need them. The book's practice is to prove everything or to name the result at its point of use and say plainly that it is not proved. Here is the complete list, section by section; each item is flagged again in the section that quotes it.

- **§02** — that Chapter 2's ordering of elimination, which updates the whole trailing block at each step, satisfies the same backward error bound as the ordering §02 displays. The section also declines to quantify the seam between that bound, which is about the factors the model computes, and the growth bound, which is about exact elimination. Separately, and not a quoted theorem at all: partial pivoting is **not** shown to be backward stable, and §02 says so rather than tidying it.
- **§03** — Wilkinson's accumulated backward error for a complete Householder factorization, of which §03 proves the one-reflection case; and the rates at which classical and modified Gram–Schmidt lose orthogonality, $u\kappa_2(\mathbf{A})^2$ and $u\kappa_2(\mathbf{A})$.
- **§04** — that Rayleigh quotient iteration converges at a quadratic rate, not a cubic one, for a general diagonalizable matrix. The cubic Hermitian rate is proved.
- **§05** — the theorem of Abel and Ruffini, quoted from Chapter 10 §08, which is the reason every eigenvalue method in this chapter iterates; and the general convergence theorem of the QR algorithm, of which §05 proves the first column and hence the whole 2×2 case.
- **§06** — the Kaniel–Paige–Saad estimate for the extreme Ritz values, of which §06 proves a clean special case; and the analysis of the loss of orthogonality in Lanczos, which §06 describes and names without proving.
- **§08** — the differentiability of $t \mapsto \mathbf{Q}(t)$, which the continuous form of the Toda statement rests on. The discrete form, that the QR iterates sit on the flow at integer times, is proved.
- **§10** — not a quoted theorem but a missing subject. Chapter 12 §10 promised an argument that a sample says something about a population, and that is statistics, which this book does not develop. Section 10 proves everything deterministic, supplies the finite-population reading, and says plainly where it stops.
- **§13** — the recursive form of Strassen's error bound; Winograd's lower bound of seven multiplications for the 2×2 product; the equality of the two definitions of ω, through all arithmetic operations and through multiplications alone; every bound on ω below $\log_2 7$; and Laderman's twenty-three-product identity for 3×3 matrices, which an exercise hands to the reader.

Nothing in this book is proved from any of them. Every theorem in the chapter either proves its own case or carries what it needs as an explicit hypothesis, and since all of these enter the book here, no earlier chapter can rest on them either. The one place a quoted result is used at all is exercise C1 (b) of §13, where Laderman's identity is given to the reader as a hypothesis and the deduction from it is the reader's own.

23.0.4 What you need

This chapter draws on almost the whole book. Chapters 4, 13, 14, 21 and 22 are the exceptions: duality, bilinear forms, tensor products, affine and projective geometry, and algebras and representations are not used here. Chapter 20 supplies the sentence the chapter answers, but none of its theorems.

- **Chapter 0 §06 and §09** — the complex numbers §07 and §12 work in, and the definition

of the matrix product with its three views and the trace, which between them supply every operation count in the chapter: Theorem 0.6.2, Theorem 0.6.4, Example (Roots of Unity), Definition 0.9.9, Example (A product of square matrices), Theorem 0.9.2, Theorem 0.9.6.

- **Chapter 1 §06** — basis extension, which §06 uses to finish an orthonormal list, and "a subspace of the full dimension is the whole space", which §11 uses to identify a column space: Theorem 1.6.5, Theorem 1.6.8.
- **Chapter 2** — the invertibility criteria, rank, elimination and the LU factorization, and the incidence matrix of a network that §11 turns into the Laplacian: Theorem 2.4.4, Theorem 2.5.7, Theorem 2.5.5, Lemma 2.6.3, Lemma 2.6.1, Lemma 2.6.2, Theorem 2.6.4, Theorem 2.6.5, Example (An invertible matrix with no LU factorization), Definition 2.7.1, Proposition 2.7.4, Corollary 2.7.5, Exercise (C3: Networks in several pieces).
- **Chapter 3 §07** — similarity, the relation every eigenvalue iteration in §§04–08 preserves: Definition 3.7.2.
- **Chapter 5 §01** — that a polynomial over an infinite field is determined by the function it defines, which is how §08 turns an equality of values into an equality of characteristic polynomials: Theorem 5.1.5.
- **Chapter 6** — determinants, almost all of them for §11: the alternating properties, the definition with the triangular and transpose rules, multiplicativity and the invertibility criterion, Laplace expansion and the adjugate identity, minors and rank, and the Gram determinant that §11 turns into the matrix-tree theorem. Section 6 also uses the tridiagonal recurrence and the Vandermonde determinant, and §§05, 07 and 08 the characteristic polynomial: Theorem 6.2.1, Definition 6.4.1, Theorem 6.4.5, Theorem 6.4.6, Theorem 6.5.4, Theorem 6.5.2, Theorem 6.6.1, Theorem 6.6.2, Theorem 6.7.1, Corollary 6.7.3, Exercise (C1: Counting spanning trees), Theorem 6.8.3, Theorem 6.8.1, Theorem 6.10.2, Theorem 6.10.3.
- **Chapter 7** — block multiplication, which is what makes both fast algorithms recurse, and Schur complements, which are what elimination is: Theorem 7.1.1, Definition 7.3.1, Theorem 7.3.1, Theorem 7.3.2.
- **Chapter 8** — diagonalization for §04, the eigenvalues on the diagonal of a triangular form for §05, and Cayley–Hamilton for §08: Theorem 8.4.1, Theorem 8.7.4, Theorem 8.6.1.
- **Chapter 9** — cyclic subspaces, which are Krylov subspaces under another name, and the matrix exponential, which §08 flows along and §09 solves with: Definition 9.5.1, Definition 9.5.4, Definition 9.5.2, Definition 9.5.3, Proposition 9.5.1, Theorem 9.5.2, Theorem 9.5.6, Definition 9.9.2, Theorem 9.9.4, Corollary 9.9.5, Theorem 9.9.6, Example (A Second-Order Equation with a Repeated Root).
- **Chapter 10** — the chapter's largest single source: inner products and Pythagoras, orthonormal bases and Gram–Schmidt, projections and best approximation, least squares, self-adjointness and isometries, reflections and rotations with the QR factorization and Hessenberg form, Parseval's identity, and the orthogonal polynomials behind the three-term recurrence: Theorem 10.1.5, Corollary 10.1.6, Theorem 10.1.3, Theorem 10.1.4, Definition 10.1.3, Theorem 10.2.2, Theorem 10.2.1, Definition 10.3.2, Definition 10.3.3, Theorem 10.3.2, Theorem 10.3.5, Theorem 10.4.2, Corollary 10.4.4, Proposition 10.6.7, Definition 10.7.2, Proposition 10.7.4, Theorem 10.7.3, Definition 10.8.1, Proposition 10.8.2, Theorem 10.8.3, Theorem 10.8.1, Theorem 10.8.4, Definition 10.8.2, Theorem 10.8.5, Theorem 10.9.2, Definition 10.10.1, Proposition 10.10.1, Theorem 10.10.3.
- **Chapter 11** — the spectral theorem in both forms, and the circulants and the discrete Fourier transform that §§11 and 12 rest on: Corollary 11.4.3, Corollary 11.5.2, Definition 11.9.1, Theorem 11.9.4, Corollary 11.9.5, Theorem 11.9.3, Theorem 11.9.6, Example (The Fourier matrix of size four), Exercise (B1: Eigenvalues of small circulants).
- **Chapter 12** — positive definiteness and Cholesky, simultaneous congruence, which is exactly §09's basis of normal modes, the Loewner order, the singular value decomposition

with low-rank approximation for §10, and the pseudoinverse: Definition 12.1.1, Theorem 12.1.5, Theorem 12.1.4, Proposition 12.1.2, Theorem 12.2.3, Example (A Cholesky Factorization, and One That Fails), Definition 12.4.1, Theorem 12.4.2, Theorem 12.4.1, Example (A pencil that does not commute), Definition 12.5.1, Definition 12.8.1, Theorem 12.8.1, Definition 12.10.1, Theorem 12.10.3, Corollary 12.10.4, Definition 12.11.1.

- **Chapter 15** — norms and operator norms, the derivative of a matrix-valued function, and above all the condition number and the theorem that bounds a relative error by it: Lemma 15.1.1, Theorem 15.3.3, Theorem 15.3.2, Definition 15.6.1, Lemma 15.6.4, Theorem 15.6.5, Theorem 15.6.6, Definition 15.8.1, Proposition 15.8.2, Theorem 15.8.3, Theorem 15.8.4.
- **Chapter 16** — the Rayleigh quotient and its critical points, the min–max description of the eigenvalues, Weyl's inequalities, interlacing, and the variational description of the singular values: Definition 16.1.1, Proposition 16.1.1, Proposition 16.1.2, Proposition 16.1.3, Theorem 16.2.3, Corollary 16.2.4, Corollary 16.3.6, Lemma 16.3.5, Theorem 16.4.2, Corollary 16.4.3, Lemma 16.4.5, Theorem 16.9.4, Corollary 16.9.5.
- **Chapter 17** — two small facts, one from each end of the chapter: the coset description of an affine hull, which §10 minimizes over, and the logarithm of a positive definite matrix, which §08 needs to know which matrices its theorem covers: Proposition 17.1.4, Lemma 17.11.1.
- **Chapter 18** — the cyclic permutation that defeats the power method, the Google matrix and the PageRank rate that §04 explains, and the second-difference matrix that §09's uniform chain turns out to be: Example (The Cyclic Permutation), Theorem 18.8.2, Proposition 18.8.3, Proposition 18.9.6.
- **Chapter 19** — the perturbation bounds that turn a residual into an error bar, which is what makes every iteration in this chapter stoppable: Theorem 19.4.4, Theorem 19.6.1, Theorem 19.6.2.

23.0.5 Roadmap

- **Floating point and backward error.** The model, the constant γ_k, the backward error of an inner product, and the three words the chapter runs on: backward stable, forward error, mixed stability. Then the rule, made a theorem: forward error at most condition number times backward error.
- **Elimination, pivoting and cost.** One step of elimination is a Schur complement of a 1×1 pivot. The cost is $\frac{2}{3}n^3$, and half that for Cholesky. A triangular solve is backward stable, and so is the factorization, up to a growth factor that partial pivoting bounds by 2^{n-1} — a bound that is attained, which is why the section stops short of calling partial pivoting stable.
- **Least squares in practice.** The sensitivity of the least-squares solution involves the residual as well as $\kappa_2(\mathbf{A})$. Forming the normal equations loses twice the digits; the reflection route loses them once, because one reflection is backward stable, and classical Gram–Schmidt loses orthogonality at a rate this section states with credit.
- **The power method.** Repeated multiplication finds the dominant eigenvector at rate $|\lambda_2/\lambda_1|$, the Rayleigh quotient squares that for Hermitian matrices, a shift and an inverse pick out any eigenvalue, and updating the shift from the Rayleigh quotient makes the convergence cubic. It all fails when two eigenvalues share a modulus.
- **The QR algorithm.** Factor and reverse, repeatedly. The iterates are orthogonal iteration applied to the powers of the matrix, which is where the convergence comes from; Hessenberg form brings the cost of a step down to about $6n^2$ flops; and a shift is what turns slow convergence into fast.

- **Krylov subspaces.** The right home for an iteration that can afford only one matrix–vector product at a time. Gram–Schmidt inside that space is the Arnoldi process and gives a Hessenberg matrix, with a three-term recurrence — the Lanczos process — when the matrix is Hermitian; the eigenvalues of the small matrix interlace the large one's, and Chapter 19's bounds apply to them verbatim. In floating point the three-term economy costs orthogonality, and the section says so.
- **Steepest descent and conjugate gradients.** Solving $\mathbf{Ax} = \mathbf{b}$ by minimizing a quadratic. Steepest descent converges like $(\kappa - 1)/(\kappa + 1)$; conjugate gradients minimizes over the whole Krylov space and converges like $(\sqrt{\kappa} - 1)/(\sqrt{\kappa} + 1)$. The square root is the point, and Chebyshev polynomials, small on an interval and large just outside it, are where it comes from.
- **Lax pairs and the Toda flow.** The chapter's one piece of pure mathematics: a differential equation whose flow preserves the spectrum, and which the QR iterates sit on at integer times. That the flow's time-one map *is* a step of the algorithm is derived, but only after granting a differentiability this book has not set up. An algorithm and a differential equation can be the same object seen at two resolutions.
- **Vibrations.** Masses and springs give $\mathbf{M}\ddot{\mathbf{x}} = -\mathbf{K}\mathbf{x}$, the substitution $\mathbf{x} = e^{i\omega t}\mathbf{v}$ gives a generalized eigenproblem, and Chapter 12 gives the $\mathbf{M}$-orthonormal basis of normal modes. Stiffening raises every frequency, adding mass lowers them, and pinning a mass interlaces them.
- **Principal components.** The best-fitting k-dimensional affine subspace of a finite set of points is spanned by the leading singular vectors of the centered data matrix, and "variance explained" is a theorem rather than a convention. The covariance matrix is never formed, for §03's reason, and the inference from a sample to a population is handed back to statistics.
- **Graph Laplacians.** $\mathrm{L} = \mathbf{N}\mathbf{N}^{\top}$ for the incidence matrix of Chapter 2 §07. The multiplicity of the eigenvalue 0 counts components, the second smallest eigenvalue measures connectivity and the signs of its eigenvector split the graph, and the determinant of a reduced Laplacian counts spanning trees, which completes Chapter 6 §07.
- **The fast Fourier transform.** The Fourier matrix factors into a permutation, two half-size copies of itself and a diagonal factor. Solving the resulting recurrence gives $O(n \log n)$, and with it fast convolution, fast polynomial multiplication and fast circulant solves.
- **Fast matrix multiplication.** Two 2×2 matrices multiply with seven products instead of eight, and the recursion gives $O(n^{\log_2 7})$. The exponent ω is at least 2, which is proved; everything known about it below $\log_2 7$ is stated with credit and not proved. Strassen's algorithm satisfies a norm error bound but no entrywise one, and a small entry really can come out with every digit wrong. The section closes the chapter.

23.0.6 Named moves

- **State the machine as a definition, then prove theorems about it.** When a subject rests on something that is not mathematics, isolate it in one definition, say what kind of statement it is, and derive the rest. Everything in this chapter that mentions rounding is a consequence of Definition 23.1.1 alone, and §09 treats its two physical laws the same way.
- **Measure an answer by a change in the data that makes it exact.** The forward error is what one wants and cannot see; the backward error is what one can bound. Prove the backward statement and let the condition number convert it.
- **Count the operations, and solve the recurrence exactly.** An asymptotic order hides the constant that decides whether an algorithm is worth using. Every cost in this

chapter is a closed form or an explicit leading term.

- **A residual is an error bar.** Chapter 19's perturbation bounds turn a quantity the algorithm already has into a certificate, which is what allows an iteration to know when to stop.
- **Iterate in a subspace, not along a direction.** The Krylov space is generated by the one operation an iteration can afford, and it is large enough to contain the answer to a polynomial approximation problem whose solution is the algorithm.
- **A conserved spectrum comes from a commutator.** If $\dot{\mathrm{Ł}} = [\mathbf{B}, \mathrm{Ł}]$, then $\mathrm{Ł}(t)$ is a similarity orbit and its eigenvalues do not move; differentiating a conjugation is the whole proof.
- **A fast algorithm is a factorization.** Factor the linear map (the Fourier matrix) or the bilinear map (the matrix product) into cheap pieces and recursive calls, then count the calls against the size reduction.

23.1 Floating Point and Backward Error

Chapter 15 ended with a number and a warning. The number was $\kappa(\mathbf{A})$, which bounds how much a relative error in the data can be magnified on the way to the answer. The warning was that κ says nothing about arithmetic: it "describes a problem", and an error bound of its shape "only becomes a statement about a computation once one knows how large a perturbation the computation itself introduces". That chapter closed the door with a sentence we now have to walk through: "Conditioning bounds what *any* method can promise; whether a given method keeps that promise is stability, and it is Chapter 23's subject."

This section builds the two things that were missing. First a **model** of machine arithmetic — an assumption, stated plainly as one, because floating-point arithmetic is not a theorem of linear algebra. Then the vocabulary that turns the model into verdicts about algorithms: forward error, backward error, and stability.

23.1.1 Two answers to one question

Chapter 15 §08 left a small experiment on the reader's desk. The system was

$$\begin{aligned} 10^{-15}x_1 + x_2 &= 1, \\ x_1 + x_2 &= 2, \end{aligned}$$

whose coefficient matrix has $\kappa_\infty < 5$: by every measure of Chapter 15 this problem is as well behaved as a problem can be, and its exact solution is $(1, 1)$ to fourteen places. Eliminating x_1 with the first equation as the pivot row, and rounding to twelve significant decimal digits at every step, returns $(0, 1)$. Exchanging the two equations first, and rounding in exactly the same way, returns $(1, 1)$.

Two algorithms, one problem, one arithmetic, and one of the two answers has no correct digit in it. Nothing in Chapter 15 can tell the two apart, because κ never mentions a method. Section 2 works that example in the model below and says exactly what the exchange achieved. This section builds the language it will be said in.

23.1.2 A model of machine arithmetic

A machine holds finitely many numbers. It cannot hold $1/3$, it cannot hold $\sqrt{2}$, and between any two numbers it does hold there are infinitely many it does not. So the result of an arithmetic operation on two stored numbers is usually not a stored number, and the machine must replace it by a neighbor.

We could try to describe which numbers a particular machine stores and exactly how it rounds. That would be a description of a machine, not mathematics, and it would be obsolete before the ink dried. What is wanted instead is the *one property* of rounding that every later argument uses, elevated into an assumption.

Every operation is performed exactly and then moved to the nearest stored number, so each operation multiplies its exact answer by something within u of 1.

Definition 23.1.1 — The floating-point model

A **floating-point model** consists of a finite set $\mathcal{R} \subseteq \mathbb{R}$ of **representable numbers** with $0, 1 \in \mathcal{R}$ and $-\mathcal{R} = \mathcal{R}$, a map $\mathrm{fl}\colon \mathbb{R} \to \mathcal{R}$ sending each real number to **a nearest** element of $\mathcal{R}$, and a real number $u > 0$ called the **unit roundoff**, subject to the following.

(FP1) **(Rounding.)** For every $t \in \mathbb{R}$ in range, $\mathrm{fl}(t) = t(1+\delta)$ for some δ with $|\delta| \le u$.

(FP2) **(Arithmetic.)** For $x, y \in \mathcal{R}$ and $\odot \in \{+, -, \times, \div\}$ with $y \neq 0$ when $\odot$ is $\div$, the computed value of $x \odot y$ is $\mathrm{fl}(x \odot y)$; the computed value of $\sqrt{x}$ for $x \in \mathcal{R}$, $x \ge 0$, is $\mathrm{fl}(\sqrt{x}\,)$. Hence

$$\mathrm{fl}(x \odot y) = (x \odot y)(1+\delta), \qquad |\delta| \le u,$$

and likewise $\mathrm{fl}(\sqrt{x}) = \sqrt{x}\,(1+\delta)$ with $|\delta| \le u$.

(FP3) **(No overflow or underflow.)** Every quantity occurring in a computation we analyze is assumed to be **in range**, so that (FP1) applies to it.

Clause by clause. "A nearest element" is a mild requirement, and the only use we make of it is the observation that $|t| \le 1$ forces $|\mathrm{fl}(t)| \le 1$, because $1 \in \mathcal{R}$. (FP1) is the whole content of the word *roundoff*: the error made in storing a real number is **relative**, of size at most u, and that is essentially the only thing we will ever know about fl. (FP2) says an operation is as accurate as storing its answer would be — the machine does not do anything stupid in between. The displayed identity is what every proof in this chapter actually uses, and it is worth reading aloud: *the computed product is the exact product times* $1+\delta$. (FP3) is an honest exclusion. Numbers too large or too small for $\mathcal{R}$ break (FP1) completely, and analyzing them is a separate subject; we assume the problem away and say so each time it matters.

This is a definition, not a theorem. Nothing in Chapters 1 to 20 implies it, and nothing in this chapter proves it. It is an idealization of a machine, in the way that a frictionless plane is an idealization of a table. The arithmetic in common use satisfies it for the four operations and the square root, with u a little over 10^{-16}; a decimal machine carrying t significant digits satisfies it with $u = \frac{1}{2} \cdot 10^{1-t}$. Every statement in this chapter that mentions rounding is a theorem **about the model**, and carries exactly as much authority as the model does.

Example. (The model we compute in)

Throughout this chapter, a worked number comes from the **six-digit decimal model**: $\mathcal{R}$ is the set of numbers $\pm d_1.d_2d_3d_4d_5d_6 \times 10^e$ with digits d_i, $d_1 \neq 0$ and e in some fixed finite range, together with 0; and fl rounds to the nearest such number. (The range of e is what (FP3) lets us stop thinking about.) What is u, and what is $\mathrm{fl}(99999996)$?

Solution. Two consecutive representable numbers of the same exponent e differ by 10^{e-5}, and a number t with that exponent has $|t| \geq 10^e$. Rounding to the nearest moves t by at most half the gap, so

$$|\mathrm{fl}(t) - t| \leq \tfrac{1}{2} \cdot 10^{e-5} \leq \tfrac{1}{2} \cdot 10^{-5}|t|,$$

which is (FP1) with $u = \frac{1}{2} \cdot 10^{-5} = 5 \times 10^{-6}$.

For $\mathrm{fl}(99999996)$: the number is 9.9999996×10^7, and the two neighbors with six digits are 9.99999×10^7 and 1.00000×10^8. The second is nearer, so $\mathrm{fl}(99999996) = 10^8$. Note what happened: eight digits went in, six came out, and the two digits that were lost were the only two that distinguished 99999996 from 10^8.

Warning. **A model with an absolute error bound would be a different, and false, model.** Suppose we had written $\mathrm{fl}(x + y) = (x + y) + \delta$ with $|\delta| \leq u$. Then $\mathrm{fl}(10^6 + 1)$ would have to be within $u = 5 \times 10^{-6}$ of $10^6 + 1$, whereas a six-digit machine returns 10^6, an absolute error of 1. The error a machine makes is proportional to the size of the number it is storing; a machine is accurate in *ratio*, never in *amount*. Confusing the two is the commonest mistake in the subject, and (FP1) exists to prevent it.

Quick check. In the six-digit model, is $\mathrm{fl}(x + y) = x + y$ possible when x and y are representable and both non-zero? Is $\mathrm{fl}(x - y) = x - y$ possible when $x \neq y$?

Solution. Yes to both, and easily. $1 + 2 = 3$ is representable, so the first addition is exact. For the second, $10^8 - 99999.9 = 99900000.1$, which is *not* representable, so that particular subtraction is inexact; but $1.00001 - 1.00000 = 10^{-5}$ is representable exactly, so that subtraction is exact. The model never claims an operation *is* inexact. It claims only a bound on how inexact it can be. That both extremes occur is what makes the subject interesting: the second subtraction is performed exactly, and it is nevertheless the shape of subtraction that destroys answers, as the last example of this section will show.

23.1.3 Accumulated rounding: the constant γ_k

A single operation costs a factor $1 + \delta$. An algorithm performs many, and the factors pile up: an answer typically carries a product like $(1 + \delta_1)(1 + \delta_2) \cdots (1 + \delta_k)$, sometimes with an inverted factor where a division occurred. Carrying such products around is unbearable, so we bound them once and for all. The constant that results is used in every remaining section of this chapter.

Lemma 23.1.1 — Accumulated rounding

Let $k \geq 1$ and let $\delta_1, \dots, \delta_k$ satisfy $|\delta_i| \leq u$, and let $\rho_1, \dots, \rho_k \in \{+1, -1\}$. If $ku < 1$, then

$$\prod_{i=1}^{k} (1+\delta_i)^{\rho_i} = 1 + \theta \qquad \text{with} \qquad |\theta| \leq \gamma_k \coloneqq \frac{ku}{1-ku}.$$

Idea. Induction on k, with the two signs treated as two cases. The only thing to watch is that the recursion for γ_k survives division, where the denominator $1-u$ costs something; the definition $\gamma_k = ku/(1-ku)$ is exactly the bound that absorbs that cost.

Proof. Note first that $ku < 1$ forces $ju < 1$ for $j \leq k$, so every γ_j with $j \leq k$ is defined and positive, and $\gamma_1 \leq \gamma_2 \leq \cdots \leq \gamma_k$.

Base case $k = 1$. If $\rho_1 = +1$, then $\theta = \delta_1$ and $|\theta| \leq u \leq u/(1-u) = \gamma_1$. If $\rho_1 = -1$, then

$$\theta = \frac{1}{1+\delta_1} - 1 = \frac{-\delta_1}{1+\delta_1}, \qquad |\theta| \leq \frac{u}{1-u} = \gamma_1,$$

where $1 + \delta_1 \geq 1 - u > 0$ because $u < 1$.

Inductive step. Suppose the product of the first $k-1$ factors is $1 + \theta'$ with $|\theta'| \leq \gamma_{k-1}$, and write $\delta = \delta_k$.

If $\rho_k = +1$, then $1 + \theta = (1+\theta')(1+\delta)$, so $\theta = \theta' + \delta + \theta'\delta$ and

$$\begin{aligned} |\theta| &\leq \gamma_{k-1} + u + \gamma_{k-1}u \\ &= \frac{(k-1)u + u\big(1-(k-1)u\big) + (k-1)u^2}{1-(k-1)u} = \frac{ku}{1-(k-1)u}, \end{aligned}$$

and $1 - (k-1)u \geq 1 - ku > 0$, so this is at most $ku/(1-ku) = \gamma_k$.

If $\rho_k = -1$, then $1+\theta = (1+\theta')/(1+\delta)$, so $\theta = (\theta'-\delta)/(1+\delta)$ and $|\theta| \leq (\gamma_{k-1}+u)/(1-u)$. It remains to check that this is at most γ_k. Clearing the positive denominators $1-(k-1)u$, $1-u$ and $1-ku$, the inequality $(\gamma_{k-1}+u)/(1-u) \leq \gamma_k$ is equivalent to

$$u\big(k-(k-1)u\big)(1-ku) \leq ku\big(1-ku+(k-1)u^2\big),$$

and expanding both sides gives $k - k^2u - (k-1)u + k(k-1)u^2$ on the left against $k - k^2u + k(k-1)u^2$ on the right, after dividing by $u > 0$. The left side is the right side minus $(k-1)u$, which is at least 0, so the left side is at most the right side and the inequality holds. This proves the lemma.

■

Remark. Read γ_k as "about ku". Indeed if $ku \leq 0.01$ then $\gamma_k \leq ku/0.99 < 1.02\,ku$. The denominator is there only so that the induction above closes; it is never the point of a bound. We will also use, without further comment, that $\gamma_j \leq \gamma_k$ for $j \leq k$, and we set $\gamma_0 = 0$, which is what the formula gives and what the empty product deserves.

23.1.4 The first backward error analysis

Here is the simplest algorithm in the book: add up n products. What comes out is not $\mathbf{x}^{\top}\mathbf{y}$. But it is *exactly* $\mathbf{x}^{\top}\mathbf{y}$ for a slightly different $\mathbf{x}$ — and that turns out to be the useful thing to say.

Theorem 23.1.2 — Backward Error of an Inner Product

Let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ have representable entries, let $nu < 1$, and let the inner product be computed in the model of Definition 23.1.1 in the natural order,

$$s_1 = \mathrm{fl}(x_1 y_1), \qquad s_k = \mathrm{fl}\big(s_{k-1} + \mathrm{fl}(x_k y_k)\big) \quad (k = 2, \dots, n).$$

Then there is a vector $\Delta\mathbf{x} \in \mathbb{R}^n$ with

$$s_n = (\mathbf{x} + \Delta\mathbf{x})^{\top}\mathbf{y} \qquad \text{and} \qquad |\Delta x_i| \le \gamma_n |x_i| \ \text{ for every } i.$$

Idea. Unroll the recursion and see which rounding factors touch which term. The term $x_k y_k$ picks up one factor from its own multiplication and one from each addition it takes part in afterwards, so no term collects more than n factors. Lemma 23.1.1 converts "at most n factors" into "$1+\theta$ with $|\theta| \le \gamma_n$", and a factor attached to $x_k y_k$ can be blamed on x_k alone.

Proof. By (FP2) there are numbers δ_k and ε_k, all of modulus at most u, with

$$\mathrm{fl}(x_k y_k) = x_k y_k (1+\delta_k) \quad (1 \le k \le n),$$
$$s_k = \big(s_{k-1} + \mathrm{fl}(x_k y_k)\big)(1+\varepsilon_k) \quad (2 \le k \le n).$$

An induction on m gives

$$s_m = \sum_{k=1}^{m} x_k y_k (1+\delta_k) \prod_{j=\max(k,2)}^{m} (1+\varepsilon_j),$$

the empty product being 1: for $m = 1$ this is $s_1 = x_1 y_1(1+\delta_1)$, and the step from $m-1$ to m multiplies every existing term by $1+\varepsilon_m$ and adds the new term $x_m y_m(1+\delta_m)(1+\varepsilon_m)$, which is what the formula says.

Take $m = n$ and count factors in the k-th term. For $k = 1$ there are $1 + (n-1) = n$ of them; for $k \ge 2$ there are $1 + (n-k+1) = n-k+2 \le n$. Every factor has the form $1+\delta$ with $|\delta| \le u$, and $nu < 1$, so Lemma 23.1.1 (with all $\rho_i = +1$) gives numbers θ_k with

$$s_n = \sum_{k=1}^{n} x_k y_k (1+\theta_k), \qquad |\theta_k| \le \gamma_n.$$

Put $\Delta x_k = x_k \theta_k$. Then $|\Delta x_k| \le \gamma_n |x_k|$ and $s_n = \sum_k (x_k + \Delta x_k) y_k = (\mathbf{x} + \Delta\mathbf{x})^{\top}\mathbf{y}$. This proves the theorem.

■

The conclusion is worth staring at. The computed number is not close to $\mathbf{x}^{\top}\mathbf{y}$ — if $\mathbf{x}^{\top}\mathbf{y}$ happens to be tiny compared with $\sum_k |x_k y_k|$, it can be wrong in every digit. What the theorem says is

different and stronger in kind: *the computed number is an inner product, exactly, of data within a relative γ_n of the given data.* The algorithm has not solved a nearby problem approximately; it has solved a nearby problem exactly.

> *Remark.* The same proof, with the roles of $\mathbf{x}$ and $\mathbf{y}$ exchanged, gives $s_n = \mathbf{x}^\top(\mathbf{y} + \Delta\mathbf{y})$ with $|\Delta\mathbf{y}| \le \gamma_n|\mathbf{y}|$ entrywise. What it does **not** give is a perturbation of both at once with half the constant, and it does not give a bound on $|s_n - \mathbf{x}^\top\mathbf{y}|$ relative to $|\mathbf{x}^\top\mathbf{y}|$. Exercise (C1: When backward stability says nothing) makes the last point precise. For complex $\mathbf{x}, \mathbf{y}$ the operations $+$, $\times$ are themselves built from several real operations, so the model must be applied to those; the resulting bound has the same shape with a modestly larger constant, and we do not prove it here or use it.

23.1.5 Forward error, backward error, stability

We can now name what Theorem 23.1.2 did, and the alternative it declined to do. Fix a **problem**: a map $f\colon D \to \mathbb{R}^m$ from data to answers, where D is a set of admissible data in some $\mathbb{R}^N$. The set D always consists of **real** data and is never cut down to the representable ones: for the problems of this chapter it is all of $\mathbb{R}^N$, or all invertible matrices, and it has to be, because the perturbed datum $\mathbf{a} + \Delta\mathbf{a}$ below must lie in it. An **algorithm** for f is a map $\widehat{f}$ — defined at the representable data, and sending each of them to whatever the computation actually returns in the model, rounding and all. Two numbers measure how the second differs from the first.

Definition 23.1.2 — Forward and backward error

Let f be a problem, $\widehat{f}$ an algorithm for it, and $\mathbf{a} \in D$ a representable datum with $f(\mathbf{a}) \neq \mathbf{0}$. The **forward error** of $\widehat{f}$ at $\mathbf{a}$ is the relative error in the answer,

$$\frac{\|\widehat{f}(\mathbf{a}) - f(\mathbf{a})\|}{\|f(\mathbf{a})\|}.$$

The **backward error** of $\widehat{f}$ at $\mathbf{a}$ is the smallest relative perturbation of the data that accounts for the computed answer exactly,

$$\inf\Big\{ \frac{\|\Delta\mathbf{a}\|}{\|\mathbf{a}\|} \;:\; \mathbf{a} + \Delta\mathbf{a} \in D \text{ and } f(\mathbf{a} + \Delta\mathbf{a}) = \widehat{f}(\mathbf{a}) \Big\},$$

with the convention that it is ∞ when no such $\Delta\mathbf{a}$ exists.

The forward error is what a user wants to know and can almost never compute, since it needs $f(\mathbf{a})$. The backward error is what an analyst can bound, because bounding it only requires *exhibiting* one $\Delta\mathbf{a}$, which a proof like the one above hands over for free. An algorithm whose backward error is always as small as the arithmetic allows is the best one can hope for.

A backward stable algorithm returns the exact answer to a question you might as well have asked.

Definition 23.1.3 — Backward stability

Let $f\colon D \to \mathbb{R}^m$ be a problem. An algorithm $\widehat{f}$ for f, running in a floating-point model with unit roundoff u, is **backward stable** if there is a constant c, depending only on

the dimensions of the data and **not** on the data itself or on u, such that for every representable $\mathbf{a} \in D$ there exists $\Delta\mathbf{a} \in \mathbb{R}^N$ with

$$\mathbf{a} + \Delta\mathbf{a} \in D, \qquad \widehat{f}(\mathbf{a}) = f(\mathbf{a} + \Delta\mathbf{a}), \qquad \|\Delta\mathbf{a}\| \le c\,u\,\|\mathbf{a}\|.$$

The small words carry the weight. **For every a**: one lucky datum proves nothing. c **independent of the data**: a "constant" allowed to grow with $\|\mathbf{a}\|$ or with κ would make the definition vacuous. c **independent of** u: the bound must improve when the arithmetic does. The constant is allowed to depend on n, and in practice always does — γ_n is about nu, not u — which is why "backward stable" is a statement about a *family* of algorithms indexed by size, and why nobody worries much about a factor of n.

By Theorem 23.1.2, the natural inner product algorithm is backward stable as an algorithm in $\mathbf{x}$ for the problem $\mathbf{x} \mapsto \mathbf{x}^{\top}\mathbf{y}$ with $\mathbf{y}$ fixed, on the domain $D = \mathbb{R}^n$. Take $c = 1.02\,n$, which depends on the dimension alone. Indeed the entrywise bound $|\Delta\mathbf{x}| \le \gamma_n|\mathbf{x}|$ implies $\|\Delta\mathbf{x}\| \le \gamma_n\|\mathbf{x}\|$ in each of the norms $\|\cdot\|_1$, $\|\cdot\|_2$, $\|\cdot\|_\infty$, and $\gamma_n \le 1.02\,nu$ in every model with $nu \le 0.01$, by the remark after Lemma 23.1.1. (Restricting to such models is how a bound stated with γ_n is turned into one with a constant independent of u, and we do it silently from here on.)

Some algorithms are not backward stable and are not bad either: they perturb the data a little *and* the answer a little, and neither perturbation alone accounts for the result. The weaker notion that covers them is worth naming, so that we never have to claim more than we have proved.

Definition 23.1.4 — Mixed forward-backward stability

An algorithm $\widehat{f}$ for $f\colon D \to \mathbb{R}^m$ is **mixed forward-backward stable** if there is a constant c, depending only on the dimensions, such that for every representable $\mathbf{a} \in D$ there are $\Delta\mathbf{a}$ and $\Delta\mathbf{y}$ with $\mathbf{a} + \Delta\mathbf{a} \in D$ and

$$\widehat{f}(\mathbf{a}) = f(\mathbf{a} + \Delta\mathbf{a}) + \Delta\mathbf{y}, \qquad \|\Delta\mathbf{a}\| \le cu\|\mathbf{a}\|, \qquad \|\Delta\mathbf{y}\| \le cu\|f(\mathbf{a} + \Delta\mathbf{a})\|.$$

Backward stability is the special case $\Delta\mathbf{y} = \mathbf{0}$, so it is the stronger statement of the two. A mixed stable algorithm does **not** satisfy the hypothesis of the next theorem: its $\Delta\mathbf{y}$ contributes a further term to the forward error, and we do not estimate that term anywhere in this chapter. Where a method in this chapter is only mixed stable, we say so, and we claim nothing more about it than the definition gives.

Warning. **Backward stable does not mean accurate, and inaccurate does not mean unstable.** A backward stable algorithm commits to nothing about the forward error except what the *problem* allows, and for an ill-conditioned problem that is very little. Conversely, an algorithm can return an accurate answer on one datum by luck while being backward unstable. The two words describe different objects: conditioning belongs to f, stability belongs to $\widehat{f}$. Chapter 15 §08 promised exactly this: "Chapter 23 draws the distinction properly, defines backward stability, and proves which of the algorithms in this book have it." Definition 23.1.3 is the definition; the proofs occupy Sections 2 and 3, and the next theorem is the only bridge between the two sides.

23.1.6 Multiplying the two together

The rule of thumb everyone quotes is *forward error* $\lesssim$ *condition number* $\times$ *backward error*. For linear systems it is not a rule of thumb at all. It is Theorem 15.8.3 with a different reading of the same symbols.

Theorem 23.1.3 — Forward Error from Backward Error

Let $\mathbf{A} \in M_n(\mathbb{C})$ be invertible, $\mathbf{b} \neq \mathbf{0}$, and $\mathbf{A}\mathbf{x} = \mathbf{b}$. Let $\widehat{\mathbf{x}}$ be any vector which is the exact solution of a perturbed system,

$$(\mathbf{A} + \Delta\mathbf{A})\widehat{\mathbf{x}} = \mathbf{b}, \qquad \frac{\|\Delta\mathbf{A}\|}{\|\mathbf{A}\|} \leq \eta,$$

and suppose $r \coloneqq \kappa(\mathbf{A})\,\eta < 1$. Then $\mathbf{A} + \Delta\mathbf{A}$ is invertible and

$$\frac{\|\widehat{\mathbf{x}} - \mathbf{x}\|}{\|\mathbf{x}\|} \leq \frac{r}{1 - r} = \frac{\kappa(\mathbf{A})\eta}{1 - \kappa(\mathbf{A})\eta}.$$

In particular, if $\eta = cu$ is admissible — as it is when the algorithm producing $\widehat{\mathbf{x}}$ is backward stable with constant c **for the problem $\mathbf{A} \mapsto \mathbf{A}^{-1}\mathbf{b}$ with $\mathbf{b}$ held fixed**, so that only $\mathbf{A}$ is perturbed — and if $\kappa(\mathbf{A})cu \leq \frac{1}{2}$, then the forward relative error is at most $2\kappa(\mathbf{A})cu$.

Idea. There is nothing to do: backward stability says the computed answer solves a perturbed system exactly, and Chapter 15 already bounded the effect of perturbing $\mathbf{A}$. The content of the theorem is the *translation*, not the estimate.

Proof. Since $\|\Delta\mathbf{A}\|/\|\mathbf{A}\| \leq \eta$, we have $\kappa(\mathbf{A})\|\Delta\mathbf{A}\|/\|\mathbf{A}\| \leq r < 1$, so Theorem 15.8.3 (b), applied with $\mathbf{E} = \Delta\mathbf{A}$, says that $\mathbf{A} + \Delta\mathbf{A}$ is invertible and that

$$\frac{\|\widehat{\mathbf{x}} - \mathbf{x}\|}{\|\mathbf{x}\|} \leq \frac{r'}{1 - r'}, \qquad r' \coloneqq \kappa(\mathbf{A})\frac{\|\Delta\mathbf{A}\|}{\|\mathbf{A}\|} \leq r.$$

The function $s \mapsto s/(1-s)$ is increasing on $[0, 1)$, since its derivative $(1-s)^{-2}$ is positive there, so $r'/(1 - r') \leq r/(1 - r)$. For the last claim put $\eta = cu$; then $r = \kappa(\mathbf{A})cu \leq \frac{1}{2}$ gives $1 - r \geq \frac{1}{2}$ and $r/(1 - r) \leq 2r$. This proves the theorem.

■

Remark. **When the right-hand side is perturbed too.** A solver for $\mathbf{A}\mathbf{x} = \mathbf{b}$ normally perturbs the pair $(\mathbf{A}, \mathbf{b})$, returning $\widehat{\mathbf{x}} \neq \mathbf{0}$ with

$$(\mathbf{A} + \Delta\mathbf{A})\widehat{\mathbf{x}} = \mathbf{b} + \Delta\mathbf{b}, \qquad \|\Delta\mathbf{A}\|_2 \leq cu\|\mathbf{A}\|_2, \qquad \|\Delta\mathbf{b}\|_2 \leq cu\|\mathbf{b}\|_2,$$

which is not literally the hypothesis above. One absorption repairs that. Put $\Delta\mathbf{A}' = \Delta\mathbf{A} - \Delta\mathbf{b}\,\widehat{\mathbf{x}}^*/\|\widehat{\mathbf{x}}\|_2^2$; then $(\mathbf{A} + \Delta\mathbf{A}')\widehat{\mathbf{x}} = \mathbf{b} + \Delta\mathbf{b} - \Delta\mathbf{b} = \mathbf{b}$, and the subtracted matrix is an outer product, of 2-norm $\|\Delta\mathbf{b}\|_2/\|\widehat{\mathbf{x}}\|_2$. So Theorem 23.1.3 applies in the 2-norm with

$$\eta = cu\Big(1 + \frac{\|\mathbf{b}\|_2}{\|\mathbf{A}\|_2\|\widehat{\mathbf{x}}\|_2}\Big) \leq cu\Big(1 + \frac{\|\mathbf{x}\|_2}{\|\widehat{\mathbf{x}}\|_2}\Big),$$

the last step because $\|\mathbf{b}\|_2 = \|\mathbf{A}\mathbf{x}\|_2 \leq \|\mathbf{A}\|_2\|\mathbf{x}\|_2$. That is a small multiple of cu as soon

> as the computed $\widehat{\mathbf{x}}$ is not much shorter than $\mathbf{x}$, and it is how every later appeal to the theorem for a linear solver is to be read.

Reading the bound in digits. Suppose the arithmetic has $u \approx 10^{-16}$ and the algorithm is backward stable with a modest c. The bound then reads: relative forward error at most about $\kappa(\mathbf{A}) \cdot 10^{-16}$. Taking logarithms, the computed answer may be wrong from about the $\big(16 - \log_{10}\kappa(\mathbf{A})\big)$-th significant digit onward. This is the origin of the sentence "a stable solve loses about $\log_{10}\kappa$ decimal digits". Two cautions, both real. It is an upper bound, so the loss may be smaller — Chapter 15 §08's warning that "the condition number bounds the error; it does not produce it" applies verbatim. And it is a statement about $\kappa(\mathbf{A})$ for the *problem as posed*: an algorithm that quietly poses a different problem pays that problem's condition number instead.

That last point is the whole of Chapter 15 §08's remaining ledger. Its third unpaid item read: "**Hence the comparison of the two algorithms** — that a stable implementation of the QR route loses about $\log_{10}\kappa_2(\mathbf{A})$ decimal digits while forming and solving the normal equations loses about $2\log_{10}\kappa_2(\mathbf{A})$ — is still Chapter 23's to prove." The theorem above supplies the first half of the sentence for any backward stable method. Section 3 supplies the second half and the two algorithms, using Chapter 15's own Theorem 15.8.4 for the square.

> *Quick check.* An algorithm for $\mathbf{Ax} = \mathbf{b}$ is backward stable, $\kappa(\mathbf{A}) = 10^8$, and $u = 10^{-16}$. A user reports that the computed $\widehat{\mathbf{x}}$ has only eight correct digits and concludes that the algorithm is broken. What is wrong with the conclusion?

> *Solution.* Nothing at all is wrong with the algorithm: Theorem 23.1.3 — applied after absorbing any perturbation of $\mathbf{b}$ into $\Delta\mathbf{A}$, as in the remark following it — predicts a relative forward error of about $\kappa(\mathbf{A})u = 10^{-8}$, up to the modest constant c, which is exactly eight correct digits. The loss is charged to the problem, not to the method. Chapter 15 §08 put it as sharply as it can be put: with data of limited accuracy, an ill-conditioned answer *is not determined* to more digits than that, whatever anybody computes with.

23.1.7 Cancellation, and where the damage really happens

Backward stability is a property of a whole algorithm, and algorithms are usually wrecked in one place. That place is almost always a subtraction of two nearly equal numbers. The following example is the standard one, and it repays being done digit by digit.

Example. (Two ways to solve a quadratic)

In the six-digit decimal model of Example (The model we compute in), find the two roots of

$$x^2 - 10^4 x + 1 = 0$$

by the quadratic formula $x_\pm = \tfrac{1}{2}\big(10^4 \pm \sqrt{10^8 - 4}\big)$, and then again with the smaller root computed as $x_- = 1/x_+$. Compare with the exact roots.

Solution. The exact roots. Their sum is 10^4 and their product is 1. Now $9999.9998^2 = 10^8 - 4 + 4 \times 10^{-8}$, which is just above $10^8 - 4$, so $\sqrt{10^8 - 4} = 9999.99979999\ldots$ and

$$x_+ = 9999.99989999\ldots, \qquad x_- = \frac{1}{x_+} = 1.0000000100\ldots \times 10^{-4}.$$

The formula, step by step. Each line is one operation of the model.

- $\mathrm{fl}(10^4 \times 10^4) = 10^8$, exactly representable, no error.
- $\mathrm{fl}(10^8 - 4) = \mathrm{fl}(99999996) = 1.00000 \times 10^8$, by Example (The model we compute in). **Here the two informative digits are lost**, and the relative error committed is about 4×10^{-8}, comfortably inside $u = 5 \times 10^{-6}$. The model is behaving perfectly.
- $\mathrm{fl}(\sqrt{10^8}) = 10^4$, exactly.
- $\mathrm{fl}(10^4 + 10^4) = 2 \times 10^4$ and $\mathrm{fl}(2 \times 10^4 \div 2) = 10^4$: the computed x_+ is 10^4, with relative error 10^{-8}. Excellent.
- $\mathrm{fl}(10^4 - 10^4) = 0$, exactly, and $\mathrm{fl}(0 \div 2) = 0$: the computed x_- is $\mathbf{0}$.

The repair. Compute $x_+ = 10^4$ as above, then $\mathrm{fl}(1 \div 10^4) = 10^{-4}$, whose relative error against $1.00000001 \times 10^{-4}$ is 10^{-8}.

What to conclude. The second route loses nothing; the first returns a root with no correct digit, indeed with no digits at all. And notice **where** the damage was done. The fatal subtraction $10^4 - 10^4$ was performed **exactly**: both operands were representable and so was their difference. The error was already present, manufactured four lines earlier when 99999996 was rounded to 10^8, and the subtraction merely deleted the digits the two operands had in common, which was all of them. Cancellation does not create error. It *exposes* error, by deleting the digits that were correct and promoting the ones that were not.

Warning. **A small residual is not a small error, and a small error is not a small residual.** For a computed solution $\widehat{\mathbf{x}}$ of $\mathbf{A}\mathbf{x} = \mathbf{b}$ with $\widehat{\mathbf{x}} \neq \mathbf{0}$, put $\mathbf{r} = \mathbf{b} - \mathbf{A}\widehat{\mathbf{x}}$ and

$$\Delta\mathbf{A} = \frac{\mathbf{r}\,\widehat{\mathbf{x}}^*}{\|\widehat{\mathbf{x}}\|_2^2}, \qquad \text{so that} \qquad (\mathbf{A} + \Delta\mathbf{A})\widehat{\mathbf{x}} = \mathbf{A}\widehat{\mathbf{x}} + \mathbf{r} = \mathbf{b},$$

and $\|\Delta\mathbf{A}\|_2 = \|\mathbf{r}\|_2 / \|\widehat{\mathbf{x}}\|_2$: Cauchy–Schwarz gives $\leq$, and $\Delta\mathbf{A}\widehat{\mathbf{x}} = \mathbf{r}$ attains it — the computation is the one in the proof of Theorem 19.4.4, with $\mathbf{b}$ in place of $\mu\widehat{\mathbf{x}}$. So a small relative residual *is* a small backward error, and nothing more: by Theorem 23.1.3 the forward error may still be $\kappa(\mathbf{A})$ times as large. In the other direction, an accurate $\widehat{\mathbf{x}}$ for a badly scaled $\mathbf{A}$ can have a residual far larger than one expects. Chapter 19 §04's Theorem 19.4.4 is the eigenvalue version of exactly this move, and that section named the technique: "An error analysis of this kind, which measures an answer by a change in the data that makes it exact, is a **backward error analysis**. Chapter 23 builds on it."

23.1.8 Exercises

23.1.8.1 A. Check your understanding

Exercise A1.

(a) State the three clauses of Definition 23.1.1, and say which one is an exclusion rather than an assumption about accuracy.

(b) Define the unit roundoff, and give its value for a decimal model carrying t significant digits.

(c) Define the forward error and the backward error of an algorithm at a datum, and say which of the two a user can usually measure.

(d) Decide whether each statement is correct, with a reason: (i) "a backward stable algorithm returns an answer with small forward error"; (ii) "if the computed $\widehat{\mathbf{x}}$ has a tiny residual, then $\widehat{\mathbf{x}}$ is close to $\mathbf{x}$".

(e) Why is Definition 23.1.1 called a model rather than a theorem?

Solution.

(a) (FP1) rounding is relative, with error at most u; (FP2) each operation returns the rounding of its exact result, so $\mathrm{fl}(x \odot y) = (x \odot y)(1+\delta)$ with $|\delta| \le u$; (FP3) no overflow or underflow. (FP3) is the exclusion: it does not say the arithmetic is good, it says we decline to analyze the case where it is not.

(b) u is the bound in (FP1): $|\mathrm{fl}(t) - t| \le u|t|$ for every in-range t. For a decimal model with t significant digits, $u = \frac{1}{2} \cdot 10^{1-t}$ (Example (The model we compute in) does the case $t = 6$).

(c) See Definition 23.1.2. The forward error is $\|\widehat{f}(\mathbf{a}) - f(\mathbf{a})\|/\|f(\mathbf{a})\|$, the backward error the smallest $\|\Delta\mathbf{a}\|/\|\mathbf{a}\|$ with $f(\mathbf{a}+\Delta\mathbf{a}) = \widehat{f}(\mathbf{a})$. A user can usually measure neither directly, but the backward error is the one an analyst can *bound*, because a bound needs only one exhibited $\Delta\mathbf{a}$; computing the forward error needs the exact answer, which is what the computation was for.

(d) (i) Incorrect. It returns an answer with small *backward* error; the forward error is then at most about κ times that, by Theorem 23.1.3 (after absorbing any perturbation of $\mathbf{b}$, as the remark after that theorem does), and for large κ that is no guarantee at all. (ii) Incorrect, for the same reason: a small residual is a small backward error (see the warning above), which bounds the forward error only after multiplication by $\kappa(\mathbf{A})$.

(e) Because it is an assumption about a physical machine, not a consequence of anything proved earlier in the book. Nothing in Chapters 1 to 20 mentions rounding. Everything this chapter proves about arithmetic is a theorem *about the model*, true of any machine that satisfies it and silent about one that does not.

23.1.8.2 B. Practice

Exercise B1: The γ calculus.

Assume $(j+k)u < 1$.

(a) Prove that $1 + \gamma_k = 1/(1-ku)$.

(b) Hence prove that $\gamma_j + \gamma_k + \gamma_j\gamma_k \le \gamma_{j+k}$.

(c) Explain in one sentence why (b) is the statement one needs when two separately analyzed computations are performed one after the other.

Solution.

(a) $1+\gamma_k = 1 + ku/(1-ku) = \big((1-ku)+ku\big)/(1-ku) = 1/(1-ku)$.

(b) Using (a) twice,

$$1+\gamma_j+\gamma_k+\gamma_j\gamma_k = (1+\gamma_j)(1+\gamma_k) = \frac{1}{(1-ju)(1-ku)}.$$

Now $(1-ju)(1-ku) = 1-(j+k)u+jku^2 \geq 1-(j+k)u > 0$, and inverting reverses the inequality between positive numbers, so the right-hand side is at most $1/\big(1-(j+k)u\big) = 1+\gamma_{j+k}$. Subtracting 1 gives the claim.

(c) If one stage multiplies the exact answer by $1+\theta_1$ with $|\theta_1| \leq \gamma_j$ and the next by $1+\theta_2$ with $|\theta_2| \leq \gamma_k$, the combined factor is $1+\theta_1+\theta_2+\theta_1\theta_2$, and (b) says the total is still of the form $1+\theta$ with $|\theta| \leq \gamma_{j+k}$ — the counts simply add.

Exercise B2: Summation.

Let $x_1, \dots, x_n$ be representable, let $nu < 1$, and let s_n be computed by $s_1 = x_1$, $s_k = \mathrm{fl}(s_{k-1} + x_k)$.

(a) Prove that $s_n = \sum_{k=1}^{n} x_k(1+\theta_k)$ with $|\theta_k| \leq \gamma_{n-1}$.

(b) Deduce $|s_n - \sum_k x_k| \leq \gamma_{n-1}\sum_k |x_k|$, and explain why this is **not** a bound on the relative error of s_n.

(c) Give three representable numbers in the six-digit model for which the computed sum has relative error larger than u.

Solution.

(a) By (FP2), $s_k = (s_{k-1}+x_k)(1+\varepsilon_k)$ for $2 \leq k \leq n$, with $|\varepsilon_k| \leq u$. Unrolling as in the proof of Theorem 23.1.2,

$$s_n = \sum_{k=1}^{n} x_k \prod_{j=\max(k,2)}^{n} (1+\varepsilon_j).$$

The $k=1$ and $k=2$ terms carry $n-1$ factors and the rest carry fewer, so Lemma 23.1.1 gives $|\theta_k| \leq \gamma_{n-1}$.

(b) Subtract $\sum_k x_k$ and use the triangle inequality: $|s_n - \sum_k x_k| = |\sum_k x_k\theta_k| \leq \gamma_{n-1}\sum_k |x_k|$. It is not a relative error bound because the right-hand side involves $\sum_k |x_k|$, not $|\sum_k x_k|$, and the two differ by an arbitrarily large factor when the x_k have mixed signs and cancel.

(c) Take $x_1 = 1$, $x_2 = 10^{-7}$, $x_3 = -1$, summed in that order. Then $\mathrm{fl}(1+10^{-7}) = 1$, since $1+10^{-7}$ lies strictly between the representable neighbors 1 and 1.00001 and is nearer the first; and $\mathrm{fl}(1-1) = 0$. The computed sum is 0, the true sum is 10^{-7}, and the relative error is 1. This is (b) at work: $\sum|x_k| = 2$ while $|\sum x_k| = 10^{-7}$.

Exercise B3: The model by hand.

Work in the six-digit decimal model.

(a) Compute $\mathrm{fl}(1/3)$ and verify (FP1) for it.

(b) Compute the two sides of $\mathrm{fl}\big(\mathrm{fl}(a+b)+c\big)$ and $\mathrm{fl}\big(a+\mathrm{fl}(b+c)\big)$ for $a=10^5$, $b=1$, $c=1$, and say what this shows about the model.

Solution.

(a) $1/3 = 3.333333\overline{3}\times 10^{-1}$, so $\mathrm{fl}(1/3) = 0.333333$ and $|\mathrm{fl}(1/3) - 1/3| = \frac{1}{3}\times 10^{-6}$. Dividing by $1/3$ gives a relative error of 10^{-6}, which is at most $u = 5\times 10^{-6}$.

(b) Left: $\mathrm{fl}(10^5+1) = 100001$ exactly (six digits), and $\mathrm{fl}(100001+1) = 100002$. Right: $\mathrm{fl}(1+1) = 2$, and $\mathrm{fl}(10^5+2) = 100002$. Here the two agree. Change a to 10^6: left gives $\mathrm{fl}(10^6+1) = 10^6$, then $\mathrm{fl}(10^6+1) = 10^6$; right gives $\mathrm{fl}(1+1) = 2$, then $\mathrm{fl}(10^6+2) = 10^6$ as well, since 1000002 rounds to 1.00000×10^6. Try $a = 10^6$, $b = c = 3$: left is 10^6 then 10^6; right is 6 then $\mathrm{fl}(1000006) = 1.00001\times 10^6$. The two differ. **Floating-point addition is commutative but not associative**, so the *order* of a summation is part of the algorithm, not an irrelevance — which is why Theorem 23.1.2 names the order it analyzes.

23.1.8.3 C. Going deeper

Exercise C1: When backward stability says nothing.

Let $\mathbf{x},\mathbf{y}\in\mathbb{R}^n$ and let s_n be the computed inner product of Theorem 23.1.2.

(a) Prove that $|s_n - \mathbf{x}^{\top}\mathbf{y}| \le \gamma_n |\mathbf{x}|^{\top}|\mathbf{y}|$, where $|\cdot|$ is entrywise.

(b) Deduce that if all $x_i y_i \ge 0$ then the *relative* error of s_n is at most γ_n.

(c) Give $\mathbf{x},\mathbf{y}\in\mathbb{R}^3$ with representable entries, in the six-digit model, for which the relative error of s_n is at least 1. Explain why this does not contradict Theorem 23.1.2.

Solution.

(a) By the theorem's proof, $s_n = \sum_k x_k y_k(1+\theta_k)$ with $|\theta_k|\le\gamma_n$, so

$$|s_n - \mathbf{x}^{\top}\mathbf{y}| = \Big|\sum_k x_k y_k \theta_k\Big| \le \gamma_n \sum_k |x_k||y_k| = \gamma_n |\mathbf{x}|^{\top}|\mathbf{y}|.$$

(b) If every $x_k y_k \ge 0$ then $|\mathbf{x}|^{\top}|\mathbf{y}| = \sum_k x_k y_k = \mathbf{x}^{\top}\mathbf{y}$, so (a) reads $|s_n - \mathbf{x}^{\top}\mathbf{y}| \le \gamma_n\, \mathbf{x}^{\top}\mathbf{y}$, which is the relative bound (and $\mathbf{x}^{\top}\mathbf{y} > 0$ unless every term vanishes, in which case $s_n = 0$ too).

(c) Take $\mathbf{x} = (1, 10^{-7}, -1)$ and $\mathbf{y} = (1,1,1)$, all representable. Each product $x_k y_k$ is computed exactly, so $\delta_1 = \delta_2 = \delta_3 = 0$. Then $s_1 = 1$; next $s_2 = \mathrm{fl}(1 + 10^{-7}) = 1$, which is $(1+10^{-7})(1+\varepsilon_2)$ with

$$\varepsilon_2 = \frac{-10^{-7}}{1+10^{-7}}, \qquad |\varepsilon_2| < 10^{-7} < u;$$

finally $s_3 = \mathrm{fl}(1-1) = 0$, exactly, so $\varepsilon_3 = 0$ serves. The true value is $\mathbf{x}^{\top}\mathbf{y} = 10^{-7}$, so the forward relative error is 1.

There is no contradiction. Following the proof, $\theta_1 = \theta_2 = \varepsilon_2$ and $\theta_3 = 0$, all of modulus below $u \le \gamma_3$, and indeed

$$(1+\varepsilon_2) + 10^{-7}(1+\varepsilon_2) - 1 = (1+10^{-7})(1+\varepsilon_2) - 1 = 0 = s_3.$$

So the backward perturbation $\Delta\mathbf{x} = (\varepsilon_2, 10^{-7}\varepsilon_2, 0)$ is of relative size about 10^{-7} in every coordinate: the algorithm solved a neighboring problem exactly. What made the answer worthless is the *problem*, not the method: here $|\mathbf{x}|^\top|\mathbf{y}| = 2 + 10^{-7}$ while $\mathbf{x}^\top\mathbf{y} = 10^{-7}$, so part (a)'s bound is twenty million times the quantity being computed. This is the same phenomenon as Example (Two ways to solve a quadratic), seen through the backward error.

Exercise C2: An unstable way to compute a variance.

Given $x_1, \dots, x_N$ with mean $\overline{x} = \frac{1}{N}\sum_i x_i$, the quantity $S = \sum_i (x_i - \overline{x})^2$ can be computed in one pass as $S = \sum_i x_i^2 - \frac{1}{N}\left(\sum_i x_i\right)^2$, or in two passes by forming $\overline{x}$ first.

(a) Verify the identity $\sum_i (x_i - \overline{x})^2 = \sum_i x_i^2 - \frac{1}{N}(\sum_i x_i)^2$.

(b) In the six-digit model, run both routes on $x = (10000, 10001, 10002)$, showing every operation, and compare with the exact value $S = 2$.

(c) Say which route is to be preferred and why, in the vocabulary of this section.

Solution.

(a) Expand: $\sum_i (x_i - \overline{x})^2 = \sum_i x_i^2 - 2\overline{x}\sum_i x_i + N\overline{x}^2$. Since $\sum_i x_i = N\overline{x}$, the last two terms are $-2N\overline{x}^2 + N\overline{x}^2 = -N\overline{x}^2 = -\frac{1}{N}(\sum_i x_i)^2$.

(b) *One pass.* The squares are 10^8, 100020001, 100040004; rounding each to six digits gives 1.00000×10^8, 1.00020×10^8 and 1.00040×10^8, and accumulating gives $\mathrm{fl}(1.00000\times10^8 + 1.00020\times10^8) = 2.00020\times10^8$ and then 3.00060×10^8. The sum $\sum_i x_i = 30003$ is exact, its square is 900180009, which rounds to 9.00180×10^8, and dividing by 3 gives 3.00060×10^8. Subtracting: $\mathrm{fl}(3.00060\times10^8 - 3.00060\times10^8) = \mathbf{0}$. *Two passes.* $\overline{x} = \mathrm{fl}(30003/3) = 10001$, exactly. The deviations $-1, 0, 1$ are computed exactly, their squares are $1, 0, 1$, and the sum is $\mathbf{2}$, the exact answer.

(c) The two-pass route. The one-pass route subtracts two nine-digit numbers that agree in their first six digits, so in a six-digit model it commits catastrophic cancellation and returns 0; worse, 0 is not the value of S for *any* small relative perturbation of the data. Indeed $S(\mathbf{x} + \Delta\mathbf{x}) = 0$ forces the three perturbed entries to be equal, say to v; and for $\mathbf{x} = (10000, 10001, 10002)$ the largest of $|x_i - v|$ is at least 1, whatever v is, because $x_3 - x_1 = 2$. So every $\Delta\mathbf{x}$ that accounts for the computed answer has

$$\frac{\|\Delta\mathbf{x}\|_\infty}{\|\mathbf{x}\|_\infty} \ge \frac{1}{10002} > 19\,u,$$

whereas Definition 23.1.3 allows cu. One datum bounds the constant rather than disposing of it — what this shows exactly is that no $c \le 19$ will serve for the one-pass route — but the mechanism is general, and it is the one Example (Two ways to solve a quadratic) identified. The two-pass route performs the subtraction $x_i - \overline{x}$ *first*, while the operands are still exactly representable, and nothing is ever lost. Same identity, same arithmetic, different algorithm — which is precisely the distinction between a problem and a method.

23.2 Elimination, Pivoting and Cost

Chapter 2 solved $\mathbf{Ax} = \mathbf{b}$ by elimination and packaged the work as $\mathbf{A} = \mathbf{LU}$ or $\mathbf{PA} = \mathbf{LU}$. It said nothing about how much arithmetic that costs, and almost nothing about what rounding does to it — only a remark, about a two-by-two matrix with a tiny corner entry, ending: "Chapter 23 makes this precise." Chapter 7 left a second note: "Chapter 23 reads Gaussian elimination itself as a sequence of Schur complements of 1×1 pivots." Chapter 12 left a third, that Cholesky "does about half the arithmetic of a general LU factorization" and needs no pivoting.

This section pays all three. Section 1 supplied the model and the word *backward stable*; here that word is applied to the oldest algorithm in the book. Throughout, matrices are **real**, since the representable numbers of Definition 23.1.1 are real, and $|\mathbf{M}|$ denotes the entrywise absolute value ($|m_{ij}|$), with $|\mathbf{M}| \le |\mathbf{N}|$ read entrywise.

23.2.1 Elimination is a sequence of Schur complements

Chapter 7 built a machine for one block elimination: if $\mathbf{M} = \left(\begin{smallmatrix}\mathbf{A} & \mathbf{B}\\ \mathbf{C} & \mathbf{D}\end{smallmatrix}\right)$ with $\mathbf{A}$ invertible, then subtracting $\mathbf{CA}^{-1}$ times the first block row from the second leaves $\left(\begin{smallmatrix}\mathbf{A} & \mathbf{B}\\ \mathbf{0} & \mathbf{M/A}\end{smallmatrix}\right)$, where $\mathbf{M/A} = \mathbf{D} - \mathbf{CA}^{-1}\mathbf{B}$ is the Schur complement (Definition 7.3.1, Theorem 7.3.1). Gaussian elimination is that machine run with a 1×1 block, $n-1$ times. Saying so exactly is the cleanest description of the algorithm there is, and it is what makes block versions of it possible.

Theorem 23.2.1 — Elimination Produces Schur Complements

Let $\mathbf{A} \in M_n(F)$ and $1 \le k \le n-1$, and suppose the first k steps of elimination without row swaps (Chapter 2 §06) are carried out with **non-zero pivots**, producing $\mathbf{A}^{(k)}$. Partition

$$\mathbf{A} = \begin{pmatrix}\mathbf{A}_k & \mathbf{B}\\ \mathbf{C} & \mathbf{D}\end{pmatrix}, \qquad \mathbf{A}^{(k)} = \begin{pmatrix}\mathbf{V} & \mathbf{B}'\\ \mathbf{0} & \mathbf{S}\end{pmatrix},$$

with $\mathbf{A}_k, \mathbf{V} \in M_k(F)$, the zero block being what the first k steps created. Then $\mathbf{A}_k$ is invertible and

$$\mathbf{S} = \mathbf{A}/\mathbf{A}_k = \mathbf{D} - \mathbf{C}\,\mathbf{A}_k^{-1}\mathbf{B}.$$

In particular, for $k = 1$ and $a_{11} \neq 0$, one step of elimination replaces the trailing $(n-1) \times (n-1)$ block by the Schur complement of the 1×1 pivot block.

Idea. The first k steps multiply $\mathbf{A}$ on the left by a unit lower triangular matrix whose columns $k+1, \dots, n$ are those of the identity — that is exactly what Lemma 2.6.3 (c) says, and it is the whole point. Such a matrix has block form $\left(\begin{smallmatrix}\mathbf{L}_{11} & \mathbf{0}\\ \mathbf{L}_{21} & \mathbf{I}\end{smallmatrix}\right)$. Multiply that by the partitioned $\mathbf{A}^{(k)}$, match the four blocks against $\mathbf{A}$, and the $\mathbf{L}_{11}$ cancels out of the bottom-right block, leaving the Schur complement.

Proof. Write $\boldsymbol{\ell}_j$ for the j-th multiplier vector, whose first j entries are zero, and recall from Chapter 2 §06 that step j multiplies on the left by $\mathbf{G}_j(-\boldsymbol{\ell}_j)$, with inverse $\mathbf{G}_j(\boldsymbol{\ell}_j)$

by Lemma 2.6.3 (b). Hence $\mathbf{A} = Ł_k \mathbf{A}^{(k)}$ where, by Lemma 2.6.3 (c),

$$Ł_k = \mathbf{G}_1(\boldsymbol{\ell}_1) \cdots \mathbf{G}_k(\boldsymbol{\ell}_k) = \mathbf{I} + \sum_{j=1}^{k} \boldsymbol{\ell}_j \mathbf{e}_j^\top.$$

Only columns $1, \ldots, k$ of $Ł_k$ differ from those of $\mathbf{I}$, so partitioning $Ł_k$ as $\mathbf{A}$ is partitioned gives

$$Ł_k = \begin{pmatrix} Ł_{11} & \mathbf{0} \\ Ł_{21} & \mathbf{I}_{n-k} \end{pmatrix},$$

with $Ł_{11} \in M_k(F)$ unit lower triangular, hence invertible by Lemma 2.6.1 (b).

By Theorem 7.1.1,

$$\begin{pmatrix} \mathbf{A}_k & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{pmatrix} = \begin{pmatrix} Ł_{11} & \mathbf{0} \\ Ł_{21} & \mathbf{I} \end{pmatrix} \begin{pmatrix} \mathbf{V} & \mathbf{B}' \\ \mathbf{0} & \mathbf{S} \end{pmatrix} = \begin{pmatrix} Ł_{11}\mathbf{V} & Ł_{11}\mathbf{B}' \\ Ł_{21}\mathbf{V} & Ł_{21}\mathbf{B}' + \mathbf{S} \end{pmatrix}.$$

Comparing blocks: $\mathbf{A}_k = Ł_{11}\mathbf{V}$, $\mathbf{B} = Ł_{11}\mathbf{B}'$, $\mathbf{C} = Ł_{21}\mathbf{V}$ and $\mathbf{D} = Ł_{21}\mathbf{B}' + \mathbf{S}$.

Now $\mathbf{V}$ is upper triangular with the first k pivots on its diagonal, and those are non-zero by hypothesis, so $\mathbf{V}$ is invertible by Lemma 2.6.2. Therefore $\mathbf{A}_k = Ł_{11}\mathbf{V}$ is invertible, and $\mathbf{A}_k^{-1} = \mathbf{V}^{-1}Ł_{11}^{-1}$. Hence

$$\mathbf{C}\,\mathbf{A}_k^{-1}\mathbf{B} = (Ł_{21}\mathbf{V})(\mathbf{V}^{-1}Ł_{11}^{-1})(Ł_{11}\mathbf{B}') = Ł_{21}\mathbf{B}',$$

and so $\mathbf{S} = \mathbf{D} - Ł_{21}\mathbf{B}' = \mathbf{D} - \mathbf{C}\mathbf{A}_k^{-1}\mathbf{B} = \mathbf{A}/\mathbf{A}_k$. This proves the theorem.

■

Example. (Two steps, two Schur complements)

Let

$$\mathbf{A} = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 7 & 5 \\ -1 & 4 & 8 \end{pmatrix}.$$

Carry out two steps of elimination without row swaps, then compute $\mathbf{A}/\mathbf{A}_1$ and $\mathbf{A}/\mathbf{A}_2$ directly from Definition 7.3.1, and check Theorem 23.2.1 in both cases.

Solution. The elimination. The first multipliers are $\ell_{21} = 2/1 = 2$ and $\ell_{31} = -1/1 = -1$; subtracting ℓ_{i1} times row 1 from row i gives $\mathbf{A}^{(1)}$. The second multiplier is $\ell_{32} = 6/3 = 2$, and row 3 becomes $(0, 0, 11 - 2(-1)) = (0, 0, 13)$:

$$\mathbf{A}^{(1)} = \begin{pmatrix} 1 & 2 & 3 \\ 0 & 3 & -1 \\ 0 & 6 & 11 \end{pmatrix}, \qquad \mathbf{A}^{(2)} = \begin{pmatrix} 1 & 2 & 3 \\ 0 & 3 & -1 \\ 0 & 0 & 13 \end{pmatrix}.$$

The Schur complement of the 1×1 *block.* Here $\mathbf{A}_1 = (1)$, $\mathbf{B} = \begin{pmatrix} 2 & 3 \end{pmatrix}$, $\mathbf{C} = \begin{pmatrix} 2 & -1 \end{pmatrix}^\top$

and $\mathbf{D} = \left(\begin{smallmatrix} 7 & 5 \\ 4 & 8 \end{smallmatrix}\right)$, so

$$\mathbf{A}/\mathbf{A}_1 = \mathbf{D} - \mathbf{C}\mathbf{A}_1^{-1}\mathbf{B} = \begin{pmatrix} 7 & 5 \\ 4 & 8 \end{pmatrix} - \begin{pmatrix} 2 \\ -1 \end{pmatrix}\begin{pmatrix} 2 & 3 \end{pmatrix} = \begin{pmatrix} 7 & 5 \\ 4 & 8 \end{pmatrix} - \begin{pmatrix} 4 & 6 \\ -2 & -3 \end{pmatrix} = \begin{pmatrix} 3 & -1 \\ 6 & 11 \end{pmatrix},$$

which is exactly the trailing block of $\mathbf{A}^{(1)}$.

The Schur complement of the 2×2 block. Now $\mathbf{A}_2 = \left(\begin{smallmatrix} 1 & 2 \\ 2 & 7 \end{smallmatrix}\right)$, with $\det \mathbf{A}_2 = 3$ and $\mathbf{A}_2^{-1} = \frac{1}{3}\left(\begin{smallmatrix} 7 & -2 \\ -2 & 1 \end{smallmatrix}\right)$, while $\mathbf{C} = \begin{pmatrix} -1 & 4 \end{pmatrix}$ and $\mathbf{B} = \begin{pmatrix} 3 & 5 \end{pmatrix}^{\top}$. Then

$$\mathbf{C}\mathbf{A}_2^{-1} = \tfrac{1}{3}\begin{pmatrix} -15 & 6 \end{pmatrix} = \begin{pmatrix} -5 & 2 \end{pmatrix},$$
$$\mathbf{A}/\mathbf{A}_2 = 8 - \begin{pmatrix} -5 & 2 \end{pmatrix}\begin{pmatrix} 3 \\ 5 \end{pmatrix} = 8 - (-5) = 13,$$

the trailing 1×1 block of $\mathbf{A}^{(2)}$. Both readings agree with Theorem 23.2.1, and as an arithmetic check the pivots $1, 3, 13$ multiply to 39, which is $\det \mathbf{A}$ — the corollary below says why that is no coincidence.

Two consequences come out for free. The first identifies the pivots with ratios of minors, which is how Chapter 12 §01 wrote them in Sylvester's criterion.

Corollary 23.2.2 — Pivots Are Ratios of Leading Minors

Let $\mathbf{A} \in M_n(F)$, let $1 \le k \le n-1$, and write $\mathbf{A}_j$ for the leading principal $j \times j$ submatrix of $\mathbf{A}$, with $\det \mathbf{A}_0 := 1$.

(a) If the first k pivots of elimination without row swaps are non-zero, then $\mathbf{A}_1, \dots, \mathbf{A}_k$ are invertible and the j-th pivot equals $\det \mathbf{A}_j / \det \mathbf{A}_{j-1}$ for $j \le k$.

(b) Conversely, if $\mathbf{A}_1, \dots, \mathbf{A}_{n-1}$ are invertible then elimination without row swaps succeeds on $\mathbf{A}$ with non-zero pivots, and $\mathbf{A} = \mathbf{L}\mathbf{U}$ by Theorem 2.6.4.

Proof.

(a) Invertibility of $\mathbf{A}_1, \dots, \mathbf{A}_k$ is Theorem 23.2.1 applied with $1, \dots, k$ in place of k. For $j = 1$ the pivot is $a_{11} = \det \mathbf{A}_1 / \det \mathbf{A}_0$, as claimed. For $2 \le j \le k$, the j-th pivot is the (j, j) entry of $\mathbf{A}^{(j-1)}$, which by the theorem (with $j-1$ in place of k) is the $(1,1)$ entry of $\mathbf{A}/\mathbf{A}_{j-1}$. That entry is a_{jj} minus row j of $\mathbf{C}$ times $\mathbf{A}_{j-1}^{-1}$ times column j of $\mathbf{B}$, so it involves only rows and columns $1, \dots, j$ of $\mathbf{A}$: it equals the 1×1 matrix $\mathbf{A}_j/\mathbf{A}_{j-1}$. By Theorem 7.3.2 (a), $\det \mathbf{A}_j = \det \mathbf{A}_{j-1} \cdot \det(\mathbf{A}_j/\mathbf{A}_{j-1})$, which is the claim.

(b) We show by induction on j that the j-th pivot is non-zero, for $j = 1, \dots, n-1$. For $j = 1$ the pivot is $a_{11} = \det \mathbf{A}_1 \neq 0$. Let $2 \le j \le n-1$ and suppose the first $j-1$ pivots are non-zero. Then Theorem 23.2.1 applies with $j-1$ in place of k, and the calculation in (a) identifies the j-th pivot as $\det \mathbf{A}_j / \det \mathbf{A}_{j-1}$, which is non-zero because $\mathbf{A}_j$ and $\mathbf{A}_{j-1}$ are invertible (Theorem 6.5.2). So elimination never stops, and Theorem 2.6.4 gives $\mathbf{A} = \mathbf{L}\mathbf{U}$.

∎

Quick check. The matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ has no LU factorization (Example (An invertible matrix with no LU factorization)). Which hypothesis of Corollary 23.2.2 (b) fails, and what does Theorem 23.2.1 say about it?

Solution. $\mathbf{A}_1 = (0)$ is not invertible, so (b) does not apply. Theorem 23.2.1 does not apply either: it assumes the first pivot is non-zero, and here it is 0, so the Schur complement $\mathbf{A}/\mathbf{A}_1$ is not even defined — Definition 7.3.1 requires the pivot block to be invertible. This is the whole content of Chapter 2's "elimination stops": there is no Schur complement to form.

23.2.2 What elimination costs

A **flop** is one arithmetic operation: one addition, subtraction, multiplication or division, or one square root. Counting flops is crude — it ignores which operations are slow and how data moves — but it captures how the work grows with n. We quote leading terms, writing $\frac{2}{3}n^3 + O(n^2)$ and meaning it. **The constant matters and the exponent matters more**: halving the constant is worth having, but a smaller exponent overtakes it at some size and stays ahead forever.

Proposition 23.2.3 — The Cost of Elimination

Counting each of the five operations as one flop, and counting only arithmetic on matrix and vector entries:

(a) Elimination without row swaps on $\mathbf{A} \in M_n(\mathbb{R})$ costs

$$\frac{n(n-1)(4n+1)}{6} = \tfrac{2}{3}n^3 - \tfrac{1}{2}n^2 - \tfrac{1}{6}n$$

flops, that is $\frac{2}{3}n^3 + O(n^2)$.

(b) Forward substitution with a unit lower triangular $\mathbf{L}$ costs $n^2 - n$ flops and back substitution with an upper triangular $\mathbf{U}$ costs n^2, so solving $\mathbf{Ax} = \mathbf{b}$ from a factorization costs $2n^2 - n$ flops.

(c) The Cholesky recursion of Chapter 12 §02 on a positive definite $\mathbf{A} \in M_n(\mathbb{R})$ costs

$$\frac{n(n+1)(2n+1)}{6} = \tfrac{1}{3}n^3 + \tfrac{1}{2}n^2 + \tfrac{1}{6}n$$

flops, that is $\frac{1}{3}n^3 + O(n^2)$, of which n are square roots.

Proof.

(a) At step k the algorithm computes $n-k$ multipliers, one division each, and then replaces each of the $(n-k)^2$ entries of the trailing block by $a_{ij} - \ell_{ik}a_{kj}$, two flops each. The entries below the pivot are set to zero without arithmetic. So the cost is

$$\sum_{k=1}^{n-1}\Big[(n-k) + 2(n-k)^2\Big] = \sum_{j=1}^{n-1}\big(j + 2j^2\big) = \frac{(n-1)n}{2} + \frac{(n-1)n(2n-1)}{3},$$

using $\sum_{j\le m} j = m(m+1)/2$ and $\sum_{j\le m} j^2 = m(m+1)(2m+1)/6$ with $m = n-1$. Putting the two terms over 6 gives $n(n-1)\big(3+2(2n-1)\big)/6 = n(n-1)(4n+1)/6$.

(b) Forward substitution computes $x_i = b_i - \sum_{j<i} \ell_{ij} x_j$ with no division, since $\ell_{ii} = 1$: that is $2(i-1)$ flops, and $\sum_{i\le n} 2(i-1) = n(n-1)$. Back substitution computes $x_i = \big(b_i - \sum_{j>i} u_{ij} x_j\big)/u_{ii}$, which is $2(n-i)+1$ flops, and $\sum_{i\le n}\big(2(n-i)+1\big) = n(n-1)+n = n^2$.

(c) Column j of the recursion computes $\ell_{jj} = \big(a_{jj} - \sum_{k<j} \ell_{jk}^2\big)^{1/2}$, costing $2(j-1)$ flops for the sum and one square root, and then $\ell_{ij} = \big(a_{ij} - \sum_{k<j} \ell_{ik}\ell_{jk}\big)/\ell_{jj}$ for each of the $n-j$ rows below, costing $2(j-1)+1$ flops each. The total is

$$\sum_{j=1}^{n} (n-j+1)\big(2j-1\big) = \sum_{i=1}^{n} i\,(2n-2i+1)$$
$$= (2n+1)\frac{n(n+1)}{2} - 2\cdot\frac{n(n+1)(2n+1)}{6},$$

substituting $i = n-j+1$; the two terms combine to $n(n+1)(2n+1)\big(\tfrac12 - \tfrac13\big) = n(n+1)(2n+1)/6$.

■

Comparing (a) and (c): $\frac13 n^3$ against $\frac23 n^3$. This is Chapter 12 §02's "Cholesky does about half the arithmetic of a general LU factorization", now a count rather than a claim, for the reason that section gave — the recursion produces one triangular factor instead of two. Part (b) says the factorization is the expensive part: solving m systems with the same $\mathbf{A}$ costs $\frac23 n^3 + 2mn^2$, not m times $\frac23 n^3$.

23.2.3 One row at a time

Every algorithm below computes its entries the same way: accumulate a sum of products into a running total, then possibly divide. Analyzing that pattern once saves doing it three times.

Lemma 23.2.4 — One Row of Substitution

Let $m \ge 0$, let $t_1, \dots, t_m$, $y_1, \dots, y_m$, c and $d \ne 0$ be representable, and suppose

$$s_0 = c, \qquad s_p = \mathrm{fl}\big(s_{p-1} - \mathrm{fl}(t_p y_p)\big) \quad (p = 1, \dots, m), \qquad z = \mathrm{fl}(s_m/d)$$

are computed in the model of Definition 23.1.1, with $(m+1)u < 1$. Then there are $\theta_0, \dots, \theta_m$ with

$$c = d\,z\,(1+\theta_0) + \sum_{p=1}^{m} t_p y_p (1+\theta_p), \qquad |\theta_p| \le \gamma_{m+1} \ \text{ for all } p.$$

If the final division is omitted, so that $z = s_m$, the same identity holds with $d = 1$ and $|\theta_p| \le \gamma_m$.

Idea. Unroll the recursion, then divide the whole identity by the product of the accumulation factors. Dividing is the trick: it moves those factors onto c's neighbors as **inverse**

factors, which is exactly what Lemma 23.1.1 was stated to allow.

Proof. By (FP2) there are $\delta_p, \varepsilon_p, \eta$, all of modulus at most u, with $\mathrm{fl}(t_p y_p) = t_p y_p(1+\delta_p)$, $s_p = \big(s_{p-1} - t_p y_p(1+\delta_p)\big)(1+\varepsilon_p)$, and $z = (s_m/d)(1+\eta)$. Induction on m gives

$$s_m = c\prod_{p=1}^{m}(1+\varepsilon_p) - \sum_{p=1}^{m} t_p y_p (1+\delta_p)\prod_{q=p}^{m}(1+\varepsilon_q),$$

the case $m=0$ being $s_0 = c$, and the step from $m-1$ to m multiplying everything by $1+\varepsilon_m$ and subtracting the new term.

Each $1+\varepsilon_p$ is non-zero, since $|\varepsilon_p| \le u < 1$, so we may divide the identity by $\prod_{p\le m}(1+\varepsilon_p)$ and rearrange:

$$c = s_m \prod_{p=1}^{m}(1+\varepsilon_p)^{-1} + \sum_{p=1}^{m} t_p y_p (1+\delta_p)\prod_{q=1}^{p-1}(1+\varepsilon_q)^{-1}.$$

From $z = (s_m/d)(1+\eta)$ we get $s_m = d\,z\,(1+\eta)^{-1}$. So the first term is $d\,z$ times a product of $m+1$ factors of the form $(1+\delta)^{\pm 1}$ with $|\delta| \le u$, which by Lemma 23.1.1 is $1+\theta_0$ with $|\theta_0| \le \gamma_{m+1}$. The p-th term of the sum carries $1 + (p-1) = p \le m$ such factors, so it is $t_p y_p(1+\theta_p)$ with $|\theta_p| \le \gamma_p \le \gamma_{m+1}$.

If the division is omitted, the first term carries only the m inverse factors, so $|\theta_0| \le \gamma_m$, and the rest of the argument is unchanged. This proves the lemma. ∎

23.2.4 Solving a triangular system

Here is the cleanest backward error analysis in the subject, and the model for every other one in this chapter. Note in advance what it does **not** assume: nothing about the size of the diagonal entries of $\mathbf{T}$, nothing about its conditioning, and no pivoting of any kind.

Theorem 23.2.5 — Backward Error of a Triangular Solve

Let $\mathbf{T} \in M_n(\mathbb{R})$ be lower triangular with representable entries and non-zero diagonal, let $\mathbf{b} \in \mathbb{R}^n$ be representable, and let $nu < 1$. Let $\widehat{\mathbf{x}}$ be computed by forward substitution in the model: for each i, the products $t_{ij}\widehat{x}_j$ are subtracted from b_i one at a time in increasing order of j, and the result is divided by t_{ii} — that is, exactly the computation of Lemma 23.2.4 with $m = i-1$. Then there is a lower triangular $\Delta\mathbf{T}$ with

$$(\mathbf{T}+\Delta\mathbf{T})\widehat{\mathbf{x}} = \mathbf{b} \qquad \text{and} \qquad |\Delta t_{ij}| \le \gamma_i\,|t_{ij}| \le \gamma_n\,|t_{ij}| \quad (j \le i).$$

The same statement, with γ_{n+1-i} in place of γ_i, holds for back substitution with an upper triangular $\mathbf{T}$.

Idea. Row i *is* the pattern of Lemma 23.2.4, with $c = b_i$, the $m = i-1$ products $t_{ij}\widehat{x}_j$,

and the final division by t_{ii}. The lemma hands back an identity in which every coefficient of $\widehat{x}_j$ is t_{ij} times something within γ_i of 1; that "something minus one", times t_{ij}, is Δt_{ij}.

Proof. Fix i. The quantities $\widehat{x}_1, \dots, \widehat{x}_{i-1}$ are already computed, hence representable, so Lemma 23.2.4 applies with $m = i-1$, $c = b_i$, $t_p = t_{ip}$, $y_p = \widehat{x}_p$, $d = t_{ii}$ and $z = \widehat{x}_i$. Since $m+1 = i \le n$ and $nu < 1$, it gives $\theta_0, \dots, \theta_{i-1}$ of modulus at most γ_i with

$$b_i = t_{ii}\widehat{x}_i(1+\theta_0) + \sum_{j<i} t_{ij}\widehat{x}_j(1+\theta_j).$$

Define $\Delta t_{ii} = t_{ii}\theta_0$, $\Delta t_{ij} = t_{ij}\theta_j$ for $j < i$, and $\Delta t_{ij} = 0$ for $j > i$. Then $\Delta\mathbf{T}$ is lower triangular, $|\Delta t_{ij}| \le \gamma_i |t_{ij}| \le \gamma_n |t_{ij}|$ since $\gamma_i \le \gamma_n$, and the display says precisely that row i of $(\mathbf{T}+\Delta\mathbf{T})\widehat{\mathbf{x}}$ equals b_i. As i was arbitrary, $(\mathbf{T}+\Delta\mathbf{T})\widehat{\mathbf{x}} = \mathbf{b}$.

For back substitution, row i has $n-i$ products instead of $i-1$, so the lemma applies with $m = n-i$ and the bound is γ_{n+1-i}. This proves the theorem. ∎

This is as strong as a backward error statement gets. The perturbation is bounded **entrywise**, and entrywise *relative to the entries of* $\mathbf{T}$ *itself*: a zero entry of $\mathbf{T}$ is not perturbed at all, and a tiny entry is perturbed only in its own last digits. So a triangular solve is backward stable in the sense of Definition 23.1.3 — with the constant $c = 1.02\,n$ in any model with $nu \le 0.01$, since $\gamma_n \le 1.02\,nu$ there — whatever $\kappa(\mathbf{T})$ may be.

Warning. **Backward stable is not accurate, and this theorem is where the point bites hardest.** Theorem 23.2.5 holds for every non-singular triangular $\mathbf{T}$. It does not say $\widehat{\mathbf{x}}$ is near $\mathbf{x}$. By Theorem 23.1.3 the forward error can be about $\kappa(\mathbf{T})\gamma_n$, and triangular matrices can be spectacularly ill-conditioned. Take the $n \times n$ matrix $\mathbf{T}$ with 1 on the diagonal and -1 everywhere above it. Its row sums of moduli are $n, n-1, \dots, 1$, so $\|\mathbf{T}\|_\infty = n$. Its inverse has 1 on the diagonal and 2^{j-i-1} in position (i,j) for $j > i$: back substitution on $\mathbf{T}\mathbf{x} = \mathbf{e}_j$ gives $x_j = 1$ and $x_i = \sum_{p>i} x_p$ for $i < j$, and each partial sum of $1, 1, 2, 4, \dots$ is the next term. Hence $\|\mathbf{T}^{-1}\|_\infty = 1 + (1 + 2 + \cdots + 2^{n-2}) = 2^{n-1}$ and $\kappa_\infty(\mathbf{T}) = n2^{n-1}$, so for $n = 60$ a backward stable solve can still return nonsense. Stability is a promise about the *data*, and a promise about the data is worth only what the conditioning of the problem makes it worth.

23.2.5 The factorization itself

For the factorization we analyze the ordering that computes each entry of Ł and $\mathbf{U}$ by one accumulation. In exact arithmetic it produces the same factors as Chapter 2's row operations — for invertible $\mathbf{A}$ this is Theorem 2.6.5 — but it groups the arithmetic differently, and rounding notices the difference.

Algorithm. **Elimination, one entry at a time.** Input: $\mathbf{A} \in M_n(\mathbb{R})$. Set $\ell_{ii} = 1$. For $i = 1, 2, \dots, n$:

- for $j = i, \dots, n$, put $u_{ij} = a_{ij} - \sum_{k<i} \ell_{ik} u_{kj}$;
- if $u_{ii} = 0$, stop; otherwise for $r = i+1, \dots, n$, put $\ell_{ri} = \big(a_{ri} - \sum_{k<i} \ell_{rk} u_{ki}\big)/u_{ii}$.

Theorem 23.2.6 — Backward Error of a Factorization

Let $\mathbf{A} \in M_n(\mathbb{R})$ have representable entries, let $nu < 1$, and suppose the algorithm above runs to completion in the model of Definition 23.1.1, producing $\widehat{\mathrm{L}}$ and $\widehat{\mathbf{U}}$. Then

$$\widehat{\mathrm{L}}\widehat{\mathbf{U}} = \mathbf{A} + \Delta\mathbf{A} \qquad \text{with} \qquad |\Delta\mathbf{A}| \le \gamma_n \, |\widehat{\mathrm{L}}| \, |\widehat{\mathbf{U}}|$$

entrywise.

Idea. Each entry is one application of Lemma 23.2.4: the entries of $\mathbf{U}$ with no division, the entries of L with one. In both cases the lemma returns a_{ij} as a sum of the products $\widehat{\ell}_{ip}\widehat{u}_{pj}$, each with its own factor $1+\theta_p$. Collecting the terms is exactly forming the (i,j) entry of $\widehat{\mathrm{L}}\widehat{\mathbf{U}}$, and the θ_p are what is left over.

Proof. *Case $i \le j$.* The computation of $\widehat{u}_{ij}$ is Lemma 23.2.4 with $m = i-1$, $c = a_{ij}$, $t_p = \widehat{\ell}_{ip}$, $y_p = \widehat{u}_{pj}$, no division and $z = \widehat{u}_{ij}$. Writing θ_i for the θ_0 of the lemma, and using $\widehat{\ell}_{ii} = 1$,

$$a_{ij} = \sum_{p=1}^{i} \widehat{\ell}_{ip}\widehat{u}_{pj}(1+\theta_p), \qquad |\theta_p| \le \gamma_{i-1}.$$

(For $i = 1$ the sum has one term and $\theta_1 = 0$.) Since $\widehat{\ell}_{ip} = 0$ for $p > i$, the sum without the θ_p is $(\widehat{\mathrm{L}}\widehat{\mathbf{U}})_{ij}$. Hence

$$\left|a_{ij} - (\widehat{\mathrm{L}}\widehat{\mathbf{U}})_{ij}\right| = \left|\sum_{p\le i} \widehat{\ell}_{ip}\widehat{u}_{pj}\theta_p\right| \le \gamma_{i-1} \sum_{p\le i} |\widehat{\ell}_{ip}||\widehat{u}_{pj}| = \gamma_{i-1}\big(|\widehat{\mathrm{L}}||\widehat{\mathbf{U}}|\big)_{ij},$$

the last equality again because $\widehat{\ell}_{ip} = 0$ for $p > i$.

Case $i > j$. The computation of $\widehat{\ell}_{ij}$ is Lemma 23.2.4 with $m = j-1$, $c = a_{ij}$, $t_p = \widehat{\ell}_{ip}$, $y_p = \widehat{u}_{pj}$, $d = \widehat{u}_{jj}$ and $z = \widehat{\ell}_{ij}$. Writing θ_j for θ_0,

$$a_{ij} = \sum_{p=1}^{j} \widehat{\ell}_{ip}\widehat{u}_{pj}(1+\theta_p), \qquad |\theta_p| \le \gamma_j.$$

Since $\widehat{u}_{pj} = 0$ for $p > j$, the sum without the θ_p is again $(\widehat{\mathrm{L}}\widehat{\mathbf{U}})_{ij}$, and the same estimate gives $|a_{ij} - (\widehat{\mathrm{L}}\widehat{\mathbf{U}})_{ij}| \le \gamma_j(|\widehat{\mathrm{L}}||\widehat{\mathbf{U}}|)_{ij}$.

In both cases the constant is at most γ_n. This proves the theorem. ∎

Remark. **What is proved and what is not.** The theorem is about the ordering displayed above. Chapter 2's ordering, which updates the whole trailing block at each step, satisfies the same bound $|\Delta\mathbf{A}| \le \gamma_n|\widehat{\mathrm{L}}||\widehat{\mathbf{U}}|$; the proof is a different induction of comparable length, and **we do not give it here**. Nothing later in this chapter uses it. Also, the theorem assumes the algorithm completes, which in the model means every computed $\widehat{u}_{ii}$ is non-zero; it says nothing about what happens when one of them is zero, or about the case where a pivot is non-zero only by a rounding accident. One more seam will appear below: the growth bound for partial pivoting, proved in the next subsection, concerns the **exact** elimination in Chapter 2's ordering, whereas the bound just proved

> concerns the factors this ordering computes in the model. In exact arithmetic, and for invertible $\mathbf{A}$, the two orderings produce the same $\mathbf{L}$ and $\mathbf{U}$, by Theorem 2.6.5; in the model they agree only to within rounding, and we do not quantify that here. Nothing below is allowed to cross that seam quietly. Eq. 23.2.1, proved next, measures growth in the **computed** factors, which is a quantity one can read off after the fact; the a priori bound 2^{n-1} of Theorem 23.2.8 is a statement about exact elimination. The three places that put the two together — the warning after Example (A matrix that really grows) and the solutions to A1 and B3 — say that they are doing so, and each of them uses the combination only to show that even its most favorable reading proves nothing.

The bound is useless until we know how big $|\widehat{\mathbf{L}}||\widehat{\mathbf{U}}|$ is, and *that* is not controlled by $\mathbf{A}$. It is controlled by what the algorithm does to $\mathbf{A}$, which is why elimination needs a pivoting rule at all. The quantity to watch has a name.

Definition 23.2.1 — Growth factor

Let elimination — with whatever pivoting rule is in force — be run on $\mathbf{A} \in M_n(\mathbb{R})$, producing an upper factor $\mathbf{U}$. The **growth factor** of that run is

$$g_n := \frac{\max_{i,j}|u_{ij}|}{\max_{i,j}|a_{ij}|},$$

the largest entry in modulus the algorithm produces, relative to the largest entry in modulus it was given. For a run in the model, $\mathbf{U}$ means the computed $\widehat{\mathbf{U}}$.

> *Remark.* The classical definition takes the maximum over **every** intermediate matrix $\mathbf{A}^{(0)} = \mathbf{A}, \mathbf{A}^{(1)}, \dots, \mathbf{A}^{(n-1)} = \mathbf{U}$ of the row-operation ordering, not only over $\mathbf{U}$. That quantity is at least g_n, so any upper bound proved for it bounds g_n too, and it is what the growth theorem of the next subsection actually estimates. The ratio above is the form the backward error bound needs.

Suppose a pivoting rule keeps every multiplier at most 1 in modulus — the next subsection exhibits one, for the algorithm above as well as for Chapter 2's ordering. Then $|\widehat{\ell}_{ip}| \le 1$, so for all i, j

$$\big(|\widehat{\mathbf{L}}||\widehat{\mathbf{U}}|\big)_{ij} \le \sum_p |\widehat{u}_{pj}| \le n \max_{p,q}|\widehat{u}_{pq}| = n\, g_n \max_{p,q}|a_{pq}|,$$

and Theorem 23.2.6 becomes

$$\max_{i,j}|\Delta a_{ij}| \;\le\; n\,\gamma_n\, g_n \max_{i,j}|a_{ij}|. \tag{23.2.1}$$

Since γ_n is about nu, the relative backward error is about $n^2 g_n u$. The dimensional factor n^2 is pessimistic and nobody minds it. **Everything therefore depends on** g_n — and on nothing else.

23.2.6 Pivoting

Proposition 23.2.7 — Partial Pivoting Bounds the Multipliers

Run elimination with **partial pivoting**: at step k, before eliminating, exchange row k with a row $r \geq k$ for which $|a_{rk}^{(k-1)}|$ is largest. Then every multiplier satisfies $|\ell_{ik}| \leq 1$, in exact arithmetic; and in the model $|\widehat{\ell}_{ik}| \leq 1$ as well.

Proof. After the exchange, the pivot $a_{kk}^{(k-1)}$ has the largest modulus in its column among rows $k, \ldots, n$. If it is zero then the whole column is zero, every multiplier is set to 0, and there is nothing to prove. Otherwise $|a_{ik}^{(k-1)}| \leq |a_{kk}^{(k-1)}|$ for $i > k$, so $|\ell_{ik}| = |a_{ik}^{(k-1)}/a_{kk}^{(k-1)}| \leq 1$.

In the model, $\widehat{\ell}_{ik} = \mathrm{fl}(x)$ for a real x with $|x| \leq 1$. Both 1 and -1 lie in $\mathcal{R}$, by Definition 23.1.1, and the one with the sign of x is at distance $1 - |x|$ from x; since $\mathrm{fl}(x)$ is a **nearest** element of $\mathcal{R}$, also $|\mathrm{fl}(x) - x| \leq 1 - |x|$. If $|\mathrm{fl}(x)|$ were greater than 1 we would get $|\mathrm{fl}(x) - x| \geq |\mathrm{fl}(x)| - |x| > 1 - |x|$, a contradiction. So $|\widehat{\ell}_{ik}| \leq 1$.

■

Remark. **The same rule, one entry at a time.** The proposition is stated for Chapter 2's ordering, which has the column entries $a_{rk}^{(k-1)}$ in hand at step k. In the entry-at-a-time algorithm those entries appear as the candidate numerators $a_{ri} - \sum_{k<i} \widehat{\ell}_{rk}\widehat{u}_{ki}$ with $r \geq i$, and partial pivoting there means: form all of them, exchange rows i and r so that the largest of them in modulus becomes $\widehat{u}_{ii}$, and only **then** divide. The proof above applies word for word, with the candidate numerator in place of $a_{rk}^{(k-1)}$ — it uses nothing about those numbers except that the divisor is the largest of them in modulus — so every multiplier of that ordering satisfies $|\widehat{\ell}_{ri}| \leq 1$ too. That is what licenses the hypothesis under which Eq. 23.2.1 was derived for the computed factors of Theorem 23.2.6.

Theorem 23.2.8 — Growth Under Partial Pivoting

In exact arithmetic, elimination with partial pivoting on any $\mathbf{A} \in M_n(\mathbb{R})$ has growth factor $g_n \leq 2^{n-1}$.

Idea. One step replaces an entry by itself minus a multiple, of modulus at most 1, of another entry. Two numbers of modulus at most M cannot make more than $2M$. Repeat $n - 1$ times.

Proof. Write $M_k = \max_{i,j} |a_{ij}^{(k)}|$, and let $\mathbf{B} = (b_{ij})$ be $\mathbf{A}^{(k-1)}$ after the row exchange of step k; an exchange only permutes entries, so $\max_{i,j} |b_{ij}| = M_{k-1}$. Every entry of $\mathbf{A}^{(k)}$ is either an entry of $\mathbf{B}$ (the rows $1, \ldots, k$ are left alone, and the entries below the pivot are set to 0) or of the form

$$a_{ij}^{(k)} = b_{ij} - \ell_{ik} b_{kj}, \qquad \left|a_{ij}^{(k)}\right| \leq |b_{ij}| + |\ell_{ik}||b_{kj}| \leq 2M_{k-1},$$

using $|\ell_{ik}| \leq 1$ from Proposition 23.2.7. Hence $M_k \leq 2M_{k-1}$ for every k, and by induction

$M_k \le 2^k M_0$. The intermediate matrices are $\mathbf{A}^{(0)}, \dots, \mathbf{A}^{(n-1)}$, so

$$\max_{i,j,k} \left|a_{ij}^{(k)}\right| = \max_{0 \le k \le n-1} M_k \le 2^{n-1} M_0,$$

which is $g_n \le 2^{n-1}$. This proves the theorem.

■

Remark. One expects the same argument in the model to give $M_k \le 2(1+u)^2 M_{k-1}$, the subtraction and the multiplication each contributing a factor $1+\delta$, and hence $g_n \le \left(2(1+u)^2\right)^{n-1}$, which for any u worth using is 2^{n-1} in all but the last digits. **We have not written that induction out**, and nothing in this section cites it: Theorem 23.2.8, the exact-arithmetic statement, is the only growth bound we have, and the passages that carry it over to a computed factorization say that they are doing so.

Quick check. Run elimination on $\left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)$ without row swaps, and again with partial pivoting, and compute g_2 each time. Does partial pivoting make the growth factor smaller?

Solution. Without a swap the multiplier is 3 and $u_{22} = 4 - 3 \cdot 2 = -2$, so $\mathbf{U} = \left(\begin{smallmatrix} 1 & 2 \\ 0 & -2 \end{smallmatrix}\right)$ and $g_2 = 2/4 = \frac{1}{2}$. With partial pivoting the rows are exchanged, the multiplier is $\frac{1}{3}$ and $u_{22} = 2 - \frac{1}{3} \cdot 4 = \frac{2}{3}$, so $\mathbf{U} = \left(\begin{smallmatrix} 3 & 4 \\ 0 & 2/3 \end{smallmatrix}\right)$ and $g_2 = 4/4 = 1$. Pivoting made the growth factor *larger*, and $g_n < 1$ is perfectly possible. Partial pivoting does not minimize growth; it bounds the multipliers, and Theorem 23.2.8 turns that into a worst-case bound — here $2^1 = 2$, which both runs respect.

The bound 2^{n-1} is dreadful, and it is attained.

Example. (A matrix that really grows)

Let $\mathbf{Y}_n \in M_n(\mathbb{R})$ have 1 on the diagonal, -1 strictly below it, 0 strictly above it except in the last column, and 1 throughout the last column. For $n = 4$,

$$\mathbf{Y}_4 = \begin{pmatrix} 1 & 0 & 0 & 1 \\ -1 & 1 & 0 & 1 \\ -1 & -1 & 1 & 1 \\ -1 & -1 & -1 & 1 \end{pmatrix}.$$

Run elimination with partial pivoting on $\mathbf{Y}_4$ and on $\mathbf{Y}_5$, and compute the growth factor of each.

Solution. The runs below are in exact arithmetic, so the factors are Ł and $\mathbf{U}$, with no hats. Every entry of $\mathbf{Y}_n$ has modulus 1, so g_n is simply the largest modulus of an entry of the resulting $\mathbf{U}$.

Step 1 on $\mathbf{Y}_4$. Column 1 is $(1, -1, -1, -1)$; all four entries have modulus 1, so the largest is already in place and no exchange is made. The multipliers are -1, so each lower row has row 1 **added** to it. Rows $2, 3, 4$ become $(0, 1, 0, 2)$, $(0, -1, 1, 2)$, $(0, -1, -1, 2)$: the last column has doubled.

Step 2. Column 2 below the diagonal is $(-1, -1)$ against the pivot 1; again no exchange, multipliers -1. Rows $3, 4$ become $(0, 0, 1, 4)$ and $(0, 0, -1, 4)$.

Step 3. Multiplier -1 again; row 4 becomes $(0,0,0,8)$. So

$$\mathbf{U} = \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 8 \end{pmatrix}, \qquad g_4 = \frac{8}{1} = 8 = 2^3.$$

For $n = 5$ the same three observations repeat once more: no exchange is ever made, every multiplier is -1, and the last column runs $1, 2, 4, 8, 16$ down the diagonal of $\mathbf{U}$, giving $g_5 = 16 = 2^4$.

Every entry of $\mathbf{Y}_n$ is ± 1, and partial pivoting does exactly what it is told; for these two sizes the bound of Theorem 23.2.8 is attained, not approached. The same three observations run by induction for every n, and Exercise (C2: The growth bound is attained for every n) carries that induction out.

Warning. **Partial pivoting is not proved stable by anything in this chapter.** Eq. 23.2.1 bounds the backward error by $n\gamma_n g_n \max_{i,j}|a_{ij}|$, where g_n is the growth in the **computed** factors, and the only bound we have on growth is Theorem 23.2.8's 2^{n-1}, for the **exact** elimination; the remark after Theorem 23.2.6 records that gap and we have not closed it. Grant it anyway, and the resulting backward error bound is about $n^2 2^{n-1} u$, which for $n = 60$ exceeds 1 and says nothing at all — so even the optimistic reading proves nothing. What is true in practice is that g_n is almost always a small multiple of 1 — but "almost always" is a statement about the matrices people meet, not a theorem, and Example (A matrix that really grows), with Exercise (C2: The growth bound is attained for every n) for general n, shows there is no theorem to be had. Partial pivoting is used because it is cheap and because its failures are rare and constructed, not because it is backward stable in the sense of Definition 23.1.3. That is an honest summary of the state of the subject, and the reader should not accept a tidier one.

23.2.7 The example Chapter 2 promised

Chapter 2 §06 ended its discussion of pivoting with a two-by-two matrix and a promise: after describing how $\left(\begin{smallmatrix} \varepsilon & 1 \\ 1 & 1 \end{smallmatrix}\right)$ makes elimination produce a computed $\mathbf{LU}$ whose $(2,2)$ entry is 0 instead of 1, it wrote "Swapping the rows first gives the harmless multiplier ε. Chapter 23 makes this precise." Here it is, made precise.

Example. (The tiny pivot, in the model)

Work in the six-digit decimal model of Example (The model we compute in), where $u = 5 \times 10^{-6}$, and take

$$\mathbf{A} = \begin{pmatrix} \varepsilon & 1 \\ 1 & 1 \end{pmatrix}, \qquad \mathbf{b} = \begin{pmatrix} 1 \\ 2 \end{pmatrix}, \qquad \varepsilon = 10^{-8}.$$

Factor and solve without an exchange, then with one. In each case compute $\widehat{\mathbf{L}}\widehat{\mathbf{U}}$ exactly and report the backward error.

Solution. The exact answer. Subtracting the first equation's ε-multiple, $(1-\varepsilon)x_1 = 1$, so

$$\mathbf{x} = \left(\frac{1}{1-\varepsilon},\ \frac{1-2\varepsilon}{1-\varepsilon}\right) = (1.00000001\ldots,\ 0.99999999\ldots).$$

Also $\kappa_\infty(\mathbf{A}) = 4/(1-\varepsilon) < 5$, exactly as in Chapter 15 §08: the problem is well conditioned.

Without the exchange. The multiplier is $\mathrm{fl}(1/\varepsilon) = 10^8$, and

$$\widehat{u}_{22} = \mathrm{fl}\big(1 - \mathrm{fl}(10^8 \cdot 1)\big) = \mathrm{fl}(1 - 10^8) = \mathrm{fl}(-99999999) = -10^8,$$

the last step by rounding to six digits. Forward substitution gives $\widehat{y}_1 = 1$ and $\widehat{y}_2 = \mathrm{fl}(2 - 10^8) = -10^8$; back substitution gives $\widehat{x}_2 = \mathrm{fl}(-10^8/-10^8) = 1$ and then

$$\widehat{x}_1 = \mathrm{fl}\big((1-1)/\varepsilon\big) = 0.$$

The computed answer is $(0, 1)$ — Chapter 15 §08's $(0, 1)$, reproduced here in a model rather than by hand-waving about digits. Multiplying the computed factors *exactly*,

$$\begin{aligned}\widehat{\mathrm{L}}\widehat{\mathrm{U}} &= \begin{pmatrix} 1 & 0 \\ 10^8 & 1 \end{pmatrix}\begin{pmatrix} 10^{-8} & 1 \\ 0 & -10^8 \end{pmatrix} \\ &= \begin{pmatrix} 10^{-8} & 1 \\ 1 & 0 \end{pmatrix} = \mathbf{A} + \Delta\mathbf{A}, \qquad \Delta\mathbf{A} = \begin{pmatrix} 0 & 0 \\ 0 & -1 \end{pmatrix}.\end{aligned}$$

So $\|\Delta\mathbf{A}\|_\infty / \|\mathbf{A}\|_\infty = \frac{1}{2}$. The backward error is not $O(u)$; it is $O(1)$. This factorization is **not** backward stable, and it is not even close.

With the exchange. Partial pivoting compares $|\varepsilon|$ with 1 and swaps, so we factor $\mathbf{PA} = \left(\begin{smallmatrix} 1 & 1 \\ \varepsilon & 1 \end{smallmatrix}\right)$ with $\mathbf{Pb} = (2, 1)$. The multiplier is $\mathrm{fl}(\varepsilon/1) = \varepsilon$, and $\widehat{u}_{22} = \mathrm{fl}(1 - \mathrm{fl}(\varepsilon \cdot 1)) = \mathrm{fl}(1 - 10^{-8}) = 1$, since $1 - 10^{-8}$ lies between the representable neighbors 0.999999 and 1 and is far nearer the second. Forward substitution gives $\widehat{y}_1 = 2$ and $\widehat{y}_2 = \mathrm{fl}(1 - \mathrm{fl}(2\varepsilon)) = \mathrm{fl}(1 - 2 \times 10^{-8}) = 1$; back substitution gives $\widehat{x}_2 = 1$ and $\widehat{x}_1 = \mathrm{fl}((2-1)/1) = 1$. The computed answer is $(1, 1)$, whose relative error against the exact $\mathbf{x}$ is about 10^{-8}, far *better* than u. Multiplying the computed factors exactly,

$$\begin{aligned}\widehat{\mathrm{L}}\widehat{\mathrm{U}} &= \begin{pmatrix} 1 & 0 \\ 10^{-8} & 1 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & 1 \\ 10^{-8} & 1 + 10^{-8} \end{pmatrix} = \mathbf{PA} + \Delta\mathbf{A}, \qquad \Delta\mathbf{A} = \begin{pmatrix} 0 & 0 \\ 0 & 10^{-8} \end{pmatrix},\end{aligned}$$

so $\|\Delta\mathbf{A}\|_\infty / \|\mathbf{A}\|_\infty = 5 \times 10^{-9}$, comfortably below u. This factorization is backward stable.

What the exchange achieved. Exactly what Eq. 23.2.1 predicts. Without it the growth factor is $g_2 = 10^8$: an entry of modulus 10^8 is created out of a matrix whose largest entry is 1, and creating it destroys the information in $a_{22} = 1$, which lies beneath its last digit. With the exchange, Proposition 23.2.7 keeps the multiplier at $\varepsilon \le 1$, $g_2 = 1$, and nothing large is ever made. Note what was **not** the problem: $\kappa_\infty(\mathbf{A}) < 5$ throughout. Chapter 15 §08 said so: "Conditioning bounds what *any* method can promise; whether a given method keeps that promise is stability."

23.2.8 Cholesky needs no pivoting

For a positive definite matrix the whole difficulty disappears, and the reason is a one-line inequality about the entries of the factor. Chapter 12 §02 asserted it — "it needs no pivoting: the recursion above never divides by something that positive definiteness allows to be zero" — and left the arithmetic half here.

Theorem 23.2.9 — Cholesky Does Not Grow

Let $\mathbf{A} \in M_n(\mathbb{R})$ be symmetric positive definite with representable entries, and let $Ł$ be its Cholesky factor, $\mathbf{A} = Ł Ł^{\top}$ with $\ell_{ii} > 0$ (Theorem 12.2.3).

(a) $|\ell_{ij}| \le \sqrt{a_{ii}}$ for all $j \le i$, and

$$\big(|Ł||Ł^{\top}|\big)_{ik} \le \sqrt{a_{ii}a_{kk}} \le \max_{p,q}|a_{pq}| \qquad \text{for all } i,k.$$

(b) Suppose $(n+1)u < 1$ and the recursion of Chapter 12 §02 runs to completion in the model, producing $\widehat{Ł}$. Then

$$\widehat{Ł}\widehat{Ł}^{\top} = \mathbf{A} + \Delta\mathbf{A}, \qquad |\Delta\mathbf{A}| \le \gamma_{n+1}\,|\widehat{Ł}|\,|\widehat{Ł}^{\top}|.$$

(c) If moreover $\gamma_{n+1} < 1$, then

$$\max_{i,j}|\Delta a_{ij}| \le \frac{\gamma_{n+1}}{1-\gamma_{n+1}} \max_{i,j}|a_{ij}|.$$

Idea. For (a): the rows of $Ł$ have known lengths, because $(Ł Ł^{\top})_{ii} = a_{ii}$ *is* the squared length of row i. An entry is no longer than its row, and Cauchy–Schwarz compares two rows. For (b): each off-diagonal entry is Lemma 23.2.4 again, and the diagonal entry is the same lemma followed by a square root, which contributes two more factors. For (c): part (b) bounds the row lengths of $\widehat{Ł}$ in terms of $\mathbf{A}$, and then (a)'s argument runs again on $\widehat{Ł}$.

Proof.

(a) Row i of $Ł$ has $\sum_p \ell_{ip}^2 = (Ł Ł^{\top})_{ii} = a_{ii}$, so every single term satisfies $\ell_{ij}^2 \le a_{ii}$. By the Cauchy–Schwarz inequality (Theorem 10.1.5) applied to the rows i and k of $|Ł|$,

$$\big(|Ł||Ł^{\top}|\big)_{ik} = \sum_p |\ell_{ip}||\ell_{kp}| \le \Big(\sum_p \ell_{ip}^2\Big)^{1/2}\Big(\sum_p \ell_{kp}^2\Big)^{1/2} = \sqrt{a_{ii}a_{kk}}.$$

Finally $\sqrt{a_{ii}a_{kk}} \le \max_p a_{pp}$, and $\max_p a_{pp} = \max_{p,q}|a_{pq}|$: the diagonal entries are positive (take $\mathbf{x} = \mathbf{e}_p$ in Definition 12.1.1), and $|a_{pq}| = |(Ł Ł^{\top})_{pq}| \le (|Ł||Ł^{\top}|)_{pq} \le \sqrt{a_{pp}a_{qq}} \le \max_p a_{pp}$, the middle step by the display just proved.

(b) Fix $i > j$. The computation $\widehat{\ell}_{ij} = \mathrm{fl}\big((a_{ij} - \sum_{k<j}\widehat{\ell}_{ik}\widehat{\ell}_{jk})/\widehat{\ell}_{jj}\big)$ is Lemma 23.2.4 with $m = j-1$ and $d = \widehat{\ell}_{jj}$, so, writing θ_j for θ_0,

$$a_{ij} = \sum_{p=1}^{j} \widehat{\ell}_{ip}\widehat{\ell}_{jp}(1+\theta_p), \qquad |\theta_p| \le \gamma_j \le \gamma_{n+1}.$$

Since $\widehat{\ell}_{jp} = 0$ for $p > j$, the sum without the θ_p is $(\widehat{\mathrm{L}}\widehat{\mathrm{L}}^{\top})_{ij}$, so

$$\left|a_{ij} - (\widehat{\mathrm{L}}\widehat{\mathrm{L}}^{\top})_{ij}\right| \le \gamma_{n+1} \sum_{p \le j} |\widehat{\ell}_{ip}||\widehat{\ell}_{jp}| = \gamma_{n+1}\big(|\widehat{\mathrm{L}}||\widehat{\mathrm{L}}^{\top}|\big)_{ij}.$$

For $i = j$, let $\widehat{s}$ be the value accumulated before the square root, so $\widehat{\ell}_{jj} = \mathrm{fl}(\sqrt{\widehat{s}}) = \sqrt{\widehat{s}}(1+\eta)$ with $|\eta| \le u$, and $\widehat{s} = \widehat{\ell}_{jj}^{\,2}(1+\eta)^{-2}$. By the **proof** of Lemma 23.2.4 with $m = j-1$ and no division — we need not just the size of θ_0' but its shape, and the proof produces $1+\theta_0'$ as the product of the $j-1$ factors $(1+\varepsilon_p)^{-1}$ —

$$a_{jj} = \widehat{s}\,(1+\theta_0') + \sum_{p<j} \widehat{\ell}_{jp}^{\,2}(1+\theta_p), \qquad |\theta_0'|, |\theta_p| \le \gamma_{j-1}.$$

Substituting $\widehat{s}$, the first term is $\widehat{\ell}_{jj}^{\,2}$ times a product of $(j-1)+2 \le n+1$ factors of the form $(1+\delta)^{\pm 1}$, which by Lemma 23.1.1 is $1+\theta_j$ with $|\theta_j| \le \gamma_{n+1}$. So again $a_{jj} = \sum_{p \le j} \widehat{\ell}_{jp}\widehat{\ell}_{jp}(1+\theta_p)$ with all $|\theta_p| \le \gamma_{n+1}$, and the displayed estimate follows as before. Since $\widehat{\mathrm{L}}$ is lower triangular, the entries with $i < j$ are the transposes of these, and $\Delta\mathbf{A}$ is symmetric.

(c) The diagonal case of (b) reads $|a_{ii} - (\widehat{\mathrm{L}}\widehat{\mathrm{L}}^{\top})_{ii}| \le \gamma_{n+1}(\widehat{\mathrm{L}}\widehat{\mathrm{L}}^{\top})_{ii}$, because $(|\widehat{\mathrm{L}}||\widehat{\mathrm{L}}^{\top}|)_{ii} = \sum_p \widehat{\ell}_{ip}^{\,2} = (\widehat{\mathrm{L}}\widehat{\mathrm{L}}^{\top})_{ii}$. Hence $(\widehat{\mathrm{L}}\widehat{\mathrm{L}}^{\top})_{ii}(1-\gamma_{n+1}) \le a_{ii}$, that is

$$\sum_p \widehat{\ell}_{ip}^{\,2} \le \frac{a_{ii}}{1-\gamma_{n+1}}.$$

Cauchy–Schwarz as in (a), now for $\widehat{\mathrm{L}}$, gives $(|\widehat{\mathrm{L}}||\widehat{\mathrm{L}}^{\top}|)_{ik} \le \sqrt{a_{ii}a_{kk}}/(1-\gamma_{n+1}) \le \max_{p,q}|a_{pq}|/(1-\gamma_{n+1})$. Substituting into (b) gives (c). This proves the theorem.

■

Compare (c) with Eq. 23.2.1. For a general matrix the backward error carried the factor g_n, which partial pivoting bounds only by 2^{n-1}, sharply. Here the same quantity is bounded by the largest entry of $\mathbf{A}$ itself, with **no growth factor and no pivoting**: the Cholesky recursion is unconditionally backward stable. The reason sits entirely in part (a) — the rows of the factor cannot be longer than the diagonal of $\mathbf{A}$ allows — and that is a fact about positive definiteness, not about arithmetic. Chapter 12 §02 called positive definiteness "the one structural hypothesis under which elimination is unconditionally safe"; this is the proof.

Warning. **Part (a) bounds $|\ell_{ij}|$ by $\sqrt{a_{ii}}$, the diagonal entry of its own row, not of its column.** The column version is false. For

$$\mathbf{A} = \begin{pmatrix} 0.01 & 0.09 \\ 0.09 & 100 \end{pmatrix},$$

which is positive definite since $0.01 > 0$ and $\det \mathbf{A} = 1 - 0.0081 > 0$ (Theorem 12.1.5 (d)), the factor is $\ell_{11} = 0.1$, $\ell_{21} = 0.9$, and $|\ell_{21}| = 0.9$ is nine times $\sqrt{a_{11}} = 0.1$. It is at most $\sqrt{a_{22}} = 10$, as (a) requires. An entry of L can be far larger than the pivot it was divided by; what it cannot exceed is the size of its own row.

23.2.9 Exercises

23.2.9.1 A. Check your understanding

Exercise A1.

(a) Define a flop and the growth factor g_n.

(b) State the partial pivoting rule, and say what Proposition 23.2.7 gets from it.

(c) State the leading term of the flop count for an LU factorization, for two triangular solves and for Cholesky.

(d) Decide whether each statement is correct, with a reason: (i) "a triangular solve needs pivoting when the diagonal entries are small"; (ii) "elimination with partial pivoting is backward stable"; (iii) "a backward stable factorization gives an accurate solution".

(e) In one sentence, what does Theorem 23.2.1 say about the trailing block after k steps?

Solution.

(a) A flop is one arithmetic operation — an addition, subtraction, multiplication, division or square root. The growth factor is $g_n = \max_{i,j}|u_{ij}| / \max_{i,j}|a_{ij}|$, the largest entry in modulus the elimination produces relative to the largest in modulus it was given (Definition 23.2.1); the classical version maximizes over every intermediate matrix as well, and is at least as large.

(b) At step k, exchange row k with the row $r \geq k$ maximizing $|a_{rk}^{(k-1)}|$. The consequence is $|\ell_{ik}| \leq 1$ for every multiplier, in exact arithmetic and in the model.

(c) $\frac{2}{3}n^3$, $2n^2$ and $\frac{1}{3}n^3$ respectively (Proposition 23.2.3); the third is half the first.

(d) (i) Incorrect. Theorem 23.2.5 holds for every non-singular triangular matrix, with no hypothesis on the diagonal and no pivoting. (ii) Incorrect as stated. The only growth bound available is Theorem 23.2.8's $g_n \leq 2^{n-1}$, proved for the exact elimination, and Example (A matrix that really grows) shows it is attained; even granting its transfer to the computed factors — the gap recorded in the remark after Theorem 23.2.6 — the resulting backward error bound $n^2 2^{n-1} u$ is vacuous for moderate n. (iii) Incorrect. It gives an accurate solution only when the problem is well conditioned; Theorem 23.1.3 supplies the missing factor $\kappa(\mathbf{A})$.

(e) It is the Schur complement $\mathbf{A}/\mathbf{A}_k$ of the leading $k \times k$ block — so elimination is the repeated formation of Schur complements of 1×1 pivots.

23.2.9.2 B. Practice

Exercise B1: A Schur complement by two routes.

Let

$$\mathbf{A} = \begin{pmatrix} 2 & 1 & -1 \\ 4 & 5 & -1 \\ -2 & 8 & 2 \end{pmatrix}.$$

(a) Carry out one step of elimination without row swaps and read off the trailing 2×2 block.

(b) Compute $\mathbf{A}/\mathbf{A}_1 = \mathbf{D} - \mathbf{C}a_{11}^{-1}\mathbf{B}$ directly from Definition 7.3.1 and check that the two agree.

(c) Carry out the second step and verify Corollary 23.2.2 (a) by computing $\det \mathbf{A}_1$, $\det \mathbf{A}_2$ and $\det \mathbf{A}_3$.

Solution.

(a) The multipliers are $\ell_{21} = 4/2 = 2$ and $\ell_{31} = -2/2 = -1$. Subtracting gives rows $(0, 3, 1)$ and $(0, 9, 1)$, so the trailing block is $\left(\begin{smallmatrix} 3 & 1 \\ 9 & 1 \end{smallmatrix}\right)$.

(b) Here $\mathbf{A}_1 = (2)$, $\mathbf{B} = (1, -1)$, $\mathbf{C} = (4, -2)^{\top}$, $\mathbf{D} = \left(\begin{smallmatrix} 5 & -1 \\ 8 & 2 \end{smallmatrix}\right)$, so

$$\mathbf{C}a_{11}^{-1}\mathbf{B} = \tfrac{1}{2}\begin{pmatrix} 4 \\ -2 \end{pmatrix}\begin{pmatrix} 1 & -1 \end{pmatrix} = \begin{pmatrix} 2 & -2 \\ -1 & 1 \end{pmatrix}, \qquad \mathbf{A}/\mathbf{A}_1 = \begin{pmatrix} 3 & 1 \\ 9 & 1 \end{pmatrix},$$

which agrees with (a), as Theorem 23.2.1 says it must.

(c) The second multiplier is $9/3 = 3$, and the second step turns $(0, 9, 1)$ into $(0, 0, 1 - 3) = (0, 0, -2)$. So the pivots are $2, 3, -2$. Now $\det \mathbf{A}_1 = 2$, $\det \mathbf{A}_2 = 10 - 4 = 6$, and $\det \mathbf{A} = 2(10 + 8) - 1(8 - 2) + (-1)(32 + 10) = 36 - 6 - 42 = -12$. The ratios are $2/1 = 2$, $6/2 = 3$ and $-12/6 = -2$: the pivots, as claimed.

Exercise B2: Growth, with and without a swap.

Let $\mathbf{A} = \begin{pmatrix} 10^{-4} & 1 \\ 1 & 1 \end{pmatrix}$, and work in the six-digit decimal model.

(a) Factor $\mathbf{A}$ without an exchange, compute g_2, and compute $\widehat{\mathrm{L}}\widehat{\mathbf{U}}$ exactly.

(b) Do the same after exchanging the rows.

(c) Compare the two backward errors with the bound of Eq. 23.2.1.

Solution.

(a) The multiplier is $\mathrm{fl}(1/10^{-4}) = 10^4$, and $\widehat{u}_{22} = \mathrm{fl}(1 - 10^4) = -9999.00$, which is exactly representable. So

$$\widehat{\mathrm{L}}\widehat{\mathbf{U}} = \begin{pmatrix} 1 & 0 \\ 10^4 & 1 \end{pmatrix}\begin{pmatrix} 10^{-4} & 1 \\ 0 & -9999 \end{pmatrix} = \begin{pmatrix} 10^{-4} & 1 \\ 1 & 1 \end{pmatrix} = \mathbf{A},$$

so here $\Delta\mathbf{A} = \mathbf{0}$: with six digits, $1 - 10^4$ is *not* rounded, and nothing is lost. The growth factor is $g_2 = 9999/1 = 9999$.

(b) After the exchange the multiplier is 10^{-4} and $\widehat{u}_{22} = \mathrm{fl}(1 - 10^{-4}) = 0.999900$, again exact, so $\widehat{\mathrm{L}}\widehat{\mathbf{U}} = \mathbf{PA}$ exactly and $g_2 = 1$.

(c) Both backward errors are zero, so both satisfy the bound. For $n = 2$ the entry-at-a-time algorithm and Chapter 2's row operations perform the very same three operations, so Eq. 23.2.1 applies to these runs as it stands, with g_2 read off the computed factors. The point is the *bound*, not the outcome: in (a) it is $2\gamma_2 g_2 \approx 4 \times 9999\,u \approx 0.2$, which permits a catastrophe, while in (b) it is about $4u$, which does not. Large growth does not force a large backward error; it removes the

guarantee that there is none, and Example (The tiny pivot, in the model) shows what happens when the permission is taken up.

Exercise B3: The Cholesky entry bound.

Let $\mathbf{A} = \begin{pmatrix} 4 & -2 & 6 \\ -2 & 5 & -1 \\ 6 & -1 & 26 \end{pmatrix}$, whose Cholesky factor was computed in Example (A Cholesky Factorization, and One That Fails) to be Ł with rows $(2,0,0)$, $(-1,2,0)$, $(3,1,4)$.

(a) Check Theorem 23.2.9 (a) entry by entry.

(b) Compute $|Ł||Ł^\top|$ and check that every entry is at most $\max_{p,q}|a_{pq}|$.

(c) What would the bound of Eq. 23.2.1 require if $\mathbf{A}$ were factored by general elimination with partial pivoting instead?

Solution.

(a) The bound is $|\ell_{ij}| \le \sqrt{a_{ii}}$. Row 1: $2 \le \sqrt{4} = 2$, with equality. Row 2: $1, 2 \le \sqrt{5} \approx 2.236$. Row 3: $3, 1, 4 \le \sqrt{26} \approx 5.099$. All hold, and the row sums of squares are $4, 5, 26$, which are a_{11}, a_{22}, a_{33} exactly.

(b) $|Ł|$ has rows $(2,0,0)$, $(1,2,0)$, $(3,1,4)$, so

$$|Ł||Ł^\top| = \begin{pmatrix} 4 & 2 & 6 \\ 2 & 5 & 5 \\ 6 & 5 & 26 \end{pmatrix}.$$

The largest entry of $\mathbf{A}$ in modulus is 26, and every entry above is at most 26 — indeed the (i,k) entry is at most $\sqrt{a_{ii}a_{kk}}$: for instance $5 \le \sqrt{5 \cdot 26} \approx 11.4$.

(c) It would require knowing g_3 for the computed factors, and the only bound available is Theorem 23.2.8's exact-arithmetic $2^2 = 4$; granting the transfer between the two (the remark after Theorem 23.2.6), Eq. 23.2.1 permits $\max|\Delta a_{ij}| \le 3\gamma_3 \cdot 4 \cdot 26 = 12\gamma_3 \cdot 26$. Theorem 23.2.9 (c) permits $\big(\gamma_4/(1-\gamma_4)\big) \cdot 26$ instead: the factor $3g_3 = 12$ disappears entirely, and the price is the step from γ_3 to $\gamma_4/(1-\gamma_4)$, which is about $\frac{4}{3}\gamma_3$. No pivoting is needed to get it.

23.2.9.3 C. Going deeper

Exercise C1: Column diagonal dominance needs no pivoting.

Call $\mathbf{A} \in M_n(\mathbb{R})$ **strictly column diagonally dominant** if $|a_{jj}| > \sum_{i \ne j}|a_{ij}|$ for every j.

(a) Show that partial pivoting makes no exchange at the first step.

(b) Show that $\mathbf{A}/\mathbf{A}_1$ is again strictly column diagonally dominant, and that each of its column sums $\sum_{i \ge 2}|a'_{ij}|$ is at most the corresponding column sum $\sum_{i \ge 1}|a_{ij}|$ of $\mathbf{A}$.

(c) Deduce that elimination without any exchanges succeeds and that $g_n < 2$.

Hint: for (c), bound every entry of every $\mathbf{A}^{(k)}$ by a column sum of $\mathbf{A}$.

Solution.

(a) Column 1 satisfies $|a_{11}| > \sum_{i\geq 2}|a_{i1}| \geq |a_{i1}|$ for each $i \geq 2$, so the entry of largest modulus in column 1 is already a_{11}, and it is non-zero.

(b) Write $a'_{ij} = a_{ij} - (a_{i1}/a_{11})a_{1j}$ for $i, j \geq 2$. For the column sums, the triangle inequality gives

$$\sum_{i\geq 2}|a'_{ij}| \leq \sum_{i\geq 2}|a_{ij}| + \frac{|a_{1j}|}{|a_{11}|}\sum_{i\geq 2}|a_{i1}| \leq \sum_{i\geq 2}|a_{ij}| + |a_{1j}| = \sum_{i\geq 1}|a_{ij}|,$$

using $\sum_{i\geq 2}|a_{i1}| < |a_{11}|$. For dominance, fix $j \geq 2$. Then

$$\sum_{\substack{i\geq 2\\ i\neq j}}|a'_{ij}| \leq \sum_{\substack{i\geq 2\\ i\neq j}}|a_{ij}| + \frac{|a_{1j}|}{|a_{11}|}\sum_{\substack{i\geq 2\\ i\neq j}}|a_{i1}| < \big(|a_{jj}| - |a_{1j}|\big) + \frac{|a_{1j}|}{|a_{11}|}\big(|a_{11}| - |a_{j1}|\big),$$

where the two strict bounds are column-j and column-1 dominance. The right side equals $|a_{jj}| - |a_{1j}||a_{j1}|/|a_{11}|$, which is at most $|a_{jj} - a_{j1}a_{1j}/a_{11}| = |a'_{jj}|$ by the reverse triangle inequality. So $\sum_{i\geq 2, i\neq j}|a'_{ij}| < |a'_{jj}|$.

(c) By (a) and (b) and induction, every Schur complement $\mathbf{A}^{(k)}$ restricted to its active block is strictly column diagonally dominant, so no exchange is ever made and no pivot is zero. By (b) and induction, the column sums of the active blocks never increase, so every entry of every $\mathbf{A}^{(k)}$ is bounded by $\max_j \sum_i |a_{ij}|$ — and the rows that have been frozen into $\mathbf{U}$ were bounded the same way when they were created. Finally, dominance gives $\sum_i |a_{ij}| < 2|a_{jj}| \leq 2\max_{p,q}|a_{pq}|$, so $g_n < 2$. Hence such matrices need no pivoting at all.

Exercise C2: The growth bound is attained for every n.

Let $\mathbf{Y}_n$ be the matrix of Example (A matrix that really grows): $y_{ii} = 1$, $y_{ij} = -1$ for $i > j$, $y_{in} = 1$ for all i, and $y_{ij} = 0$ for $j > i$ with $j < n$.

(a) Prove that partial pivoting makes no exchange at any step, and that every multiplier equals -1.

(b) Prove by induction on k that after k steps the active trailing block is again of the form $\mathbf{Y}_{n-k}$, except that its last column is 2^k times the all-ones vector.

(c) Deduce $g_n = 2^{n-1}$, and explain why this does not contradict the practical success of partial pivoting.

Solution.

(a) and (b) together, by induction. At step $k = 1$, column 1 is $(1, -1, \ldots, -1)$, every entry of modulus 1, so the pivot $y_{11} = 1$ is already of largest modulus and no exchange is made; the multipliers are $-1/1 = -1$. Subtracting -1 times row 1 from row i adds row 1 to row i. Row 1 is $(1, 0, \ldots, 0, 1)$, so for $i \geq 2$ the entries in columns $2, \ldots, n-1$ are unchanged, the entry in column 1 becomes 0, and the entry in column n becomes $1 + 1 = 2$. The trailing $(n-1) \times (n-1)$ block therefore has 1 on its diagonal, -1 below, 0 above except in the last column, and 2 throughout its last column: it is $\mathbf{Y}_{n-1}$ with the last column doubled. Since doubling one column changes neither which entry of a column has largest modulus nor the ratios within

the other columns, the same applies at every subsequent step, and after k steps the active block is $\mathbf{Y}_{n-k}$ with last column 2^k times the all-ones vector.

(b) Every entry of $\mathbf{Y}_n$ has modulus 1, so $M_0 = 1$. By (b) the largest entry ever created is the (n, n) entry after step $n-1$, namely 2^{n-1}. So $g_n = 2^{n-1}$, meeting Theorem 23.2.8 exactly.

This does not contradict anything practical: $\mathbf{Y}_n$ is a constructed matrix, and the theorem only says the *worst case* is 2^{n-1}. What the example does destroy is the hope of a theorem: no bound better than 2^{n-1} can be proved for partial pivoting, so any claim that partial pivoting is backward stable is a claim about the matrices one meets, not about all matrices. That is why Theorem 23.2.9 matters — it is a genuine theorem, for a class of matrices identified in advance.

23.3 Least Squares in Practice

Chapter 10 solved the least-squares problem twice. Section 4 of that chapter produced the normal equations $\mathbf{A}^*\mathbf{A}\mathbf{x} = \mathbf{A}^*\mathbf{b}$ (Theorem 10.4.2), and Section 8 rewrote them, once a $\mathbf{QR}$ factorization was available, as the triangular system $\mathbf{R}\mathbf{x} = \mathbf{Q}^*\mathbf{b}$. It then recommended the second route and postponed the reason: "forming $\mathbf{A}^*\mathbf{A}$ squares the sensitivity of the problem to rounding, while (†) never forms that product at all. Chapter 23 makes 'sensitivity' precise and proves the comparison; here we record only the practice."

Chapter 15 supplied half of the reason. Its Theorem 15.8.4 proved $\kappa_2(\mathbf{A}^*\mathbf{A}) = \kappa_2(\mathbf{A})^2$ and then listed what was still missing: the conditioning of the fitting problem itself, which involves the residual; the arithmetic, which needed a model; and the comparison of the two algorithms in digits. Sections 1 and 2 of this chapter built the model and the vocabulary. This section pays the three debts, in that order, and ends with the reason the reflections of Chapter 10 are the right way to produce $\mathbf{Q}$ and $\mathbf{R}$.

Throughout, $F = \mathbb{R}$ or $F = \mathbb{C}$, $\mathbf{A} \in M_{m\times n}(F)$ with $m \geq n$ and $\operatorname{rank}\mathbf{A} = n$, and $\mathbf{b} \in F^m$ is non-zero. By Corollary 10.4.4 there is then exactly one least-squares solution $\mathbf{x}$, and $\mathbf{A}^*\mathbf{A}$ is invertible. All norms are $\|\cdot\|_2$ unless a subscript says otherwise.

23.3.1 How sensitive is the problem?

Before any algorithm is judged, the problem has to be measured. Write

$$\mathbf{r} = \mathbf{b} - \mathbf{A}\mathbf{x}, \qquad \mathbf{A}\mathbf{x} = P_{\operatorname{col}(\mathbf{A})}\mathbf{b},$$

the residual and the projection of Theorem 10.4.2 (b). Since $\mathbf{r} \perp \operatorname{col}(\mathbf{A})$ and $\mathbf{A}\mathbf{x} \in \operatorname{col}(\mathbf{A})$, Pythagoras (Theorem 10.1.3) gives $\|\mathbf{b}\|^2 = \|\mathbf{A}\mathbf{x}\|^2 + \|\mathbf{r}\|^2$. So there is a unique $\theta \in [0, \pi/2]$ with

$$\cos\theta = \frac{\|\mathbf{A}\mathbf{x}\|}{\|\mathbf{b}\|}, \qquad \sin\theta = \frac{\|\mathbf{r}\|}{\|\mathbf{b}\|}, \tag{23.3.1}$$

the angle between $\mathbf{b}$ and the column space of $\mathbf{A}$. It is 0 exactly when the system is consistent and $\pi/2$ exactly when $\mathbf{A}^*\mathbf{b} = \mathbf{0}$, in which case $\mathbf{x} = \mathbf{0}$ and no relative error can be spoken of. **We assume $\theta < \pi/2$ throughout**, so $\mathbf{x} \neq \mathbf{0}$.

One number is now missing from Chapter 15's account, and Eq. 23.3.1 supplies it. Here is the sensitivity of $\mathbf{x}$ to a perturbation of the data.

Theorem 23.3.1 — Conditioning of the Least-Squares Problem

Let $\mathbf{A} \in M_{m\times n}(F)$ have rank $n \le m$, let $\mathbf{b} \neq \mathbf{0}$, let $\mathbf{x}$ be the least-squares solution of $\mathbf{Az} = \mathbf{b}$, and let $\theta < \pi/2$ be as in Eq. 23.3.1. Let $\mathbf{E} \in M_{m\times n}(F)$ and $\mathbf{f} \in F^m$, and for real t near 0 let $\mathbf{x}(t)$ be the least-squares solution of $(\mathbf{A}+t\mathbf{E})\mathbf{z} = \mathbf{b}+t\mathbf{f}$. Then $\mathbf{x}(t)$ is defined and differentiable near $t=0$, with $\mathbf{x}(0)=\mathbf{x}$, and

$$\frac{\|\mathbf{x}'(0)\|}{\|\mathbf{x}\|} \;\le\; \kappa_2(\mathbf{A})\Big(\varepsilon_{\mathbf{A}} + \frac{\varepsilon_{\mathbf{b}}}{\cos\theta}\Big) \;+\; \kappa_2(\mathbf{A})^2\,\varepsilon_{\mathbf{A}}\tan\theta,$$

where $\varepsilon_{\mathbf{A}} = \|\mathbf{E}\|/\|\mathbf{A}\|$ and $\varepsilon_{\mathbf{b}} = \|\mathbf{f}\|/\|\mathbf{b}\|$.

Idea. The least-squares solution is $\mathbf{x}(t) = \mathbf{N}(t)^{-1}\mathbf{A}(t)^*\mathbf{b}(t)$ with $\mathbf{N}(t) = \mathbf{A}(t)^*\mathbf{A}(t)$, which is a differentiable function of t because $\mathbf{N}(0)$ is invertible. Rather than differentiate that formula, differentiate the equation $\mathbf{N}(t)\mathbf{x}(t) = \mathbf{A}(t)^*\mathbf{b}(t)$ it comes from: the product rule gives three terms, two of them combine into $\mathbf{E}^*(\mathbf{b}-\mathbf{Ax}) = \mathbf{E}^*\mathbf{r}$, and the residual appears by itself. Then read every norm off a singular value decomposition: $\|(\mathbf{A}^*\mathbf{A})^{-1}\| = \sigma_n^{-2}$ is where the square comes from, and the only inequality used to finish is $\sigma_1\|\mathbf{x}\| \ge \|\mathbf{Ax}\| = \|\mathbf{b}\|\cos\theta$.

Proof. Write $\mathbf{A}(t) = \mathbf{A}+t\mathbf{E}$, $\mathbf{b}(t) = \mathbf{b}+t\mathbf{f}$ and $\mathbf{N}(t) = \mathbf{A}(t)^*\mathbf{A}(t)$. Every entry of $\mathbf{N}(t)$ is a polynomial in t, so $\mathbf{N}$ is differentiable in the sense of Definition 15.6.1, and $\mathbf{N}(0) = \mathbf{A}^*\mathbf{A}$ is invertible by Corollary 10.4.4 (c). By Theorem 15.6.5, $\mathbf{N}(t)$ is invertible on an open interval around 0 and $t \mapsto \mathbf{N}(t)^{-1}$ is differentiable there. On that interval $\operatorname{rank}\mathbf{A}(t) = n$, again by Corollary 10.4.4, so Theorem 10.4.2 has the unique solution

$$\mathbf{x}(t) = \mathbf{N}(t)^{-1}\mathbf{A}(t)^*\mathbf{b}(t),$$

differentiable by Lemma 15.6.4. (Conjugation is applied entrywise and commutes with differentiation in the real variable t, so $(\mathbf{A}(t)^*)' = \mathbf{E}^*$.)

Differentiate the identity $\mathbf{N}(t)\mathbf{x}(t) = \mathbf{A}(t)^*\mathbf{b}(t)$ at $t=0$ with Lemma 15.6.4. Since $\mathbf{N}'(0) = \mathbf{E}^*\mathbf{A} + \mathbf{A}^*\mathbf{E}$,

$$(\mathbf{E}^*\mathbf{A} + \mathbf{A}^*\mathbf{E})\mathbf{x} + \mathbf{A}^*\mathbf{A}\,\mathbf{x}'(0) = \mathbf{E}^*\mathbf{b} + \mathbf{A}^*\mathbf{f}.$$

Move the first bracket across and collect the two terms carrying $\mathbf{E}^*$:

$$\mathbf{A}^*\mathbf{A}\,\mathbf{x}'(0) = \mathbf{E}^*(\mathbf{b}-\mathbf{Ax}) - \mathbf{A}^*(\mathbf{Ex}) + \mathbf{A}^*\mathbf{f} = \mathbf{E}^*\mathbf{r} - \mathbf{A}^*(\mathbf{Ex}) + \mathbf{A}^*\mathbf{f}.$$

Hence

$$\mathbf{x}'(0) = (\mathbf{A}^*\mathbf{A})^{-1}\mathbf{E}^*\mathbf{r} \;-\; (\mathbf{A}^*\mathbf{A})^{-1}\mathbf{A}^*(\mathbf{Ex}) \;+\; (\mathbf{A}^*\mathbf{A})^{-1}\mathbf{A}^*\mathbf{f}. \qquad (*)$$

Now the two norms. Write $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$ as in Theorem 12.8.1, with $\sigma_1 \ge \cdots \ge \sigma_n > 0$. As in the proof of Theorem 15.8.4, $\mathbf{A}^*\mathbf{A} = \mathbf{V}\operatorname{diag}(\sigma_1^2,\dots,\sigma_n^2)\mathbf{V}^*$, so

$$(\mathbf{A}^*\mathbf{A})^{-1} = \mathbf{V}\operatorname{diag}(\sigma_1^{-2},\dots,\sigma_n^{-2})\mathbf{V}^*, \qquad (\mathbf{A}^*\mathbf{A})^{-1}\mathbf{A}^* = \mathbf{V}\mathbf{\Sigma}^{+}\mathbf{U}^*,$$

where $\mathbf{\Sigma}^+$ is the $n \times m$ matrix with $\sigma_1^{-1}, \dots, \sigma_n^{-1}$ on its diagonal — the second identity because $\operatorname{diag}(\sigma_i^{-2})\mathbf{\Sigma}^* = \mathbf{\Sigma}^+$. Unitary factors do not change singular values, rectangular ones included: for unitary $\mathbf{U}_1, \mathbf{V}_1$ of the right sizes, $(\mathbf{U}_1\mathbf{M}\mathbf{V}_1)^*(\mathbf{U}_1\mathbf{M}\mathbf{V}_1) = \mathbf{V}_1^*(\mathbf{M}^*\mathbf{M})\mathbf{V}_1$ is unitarily similar to $\mathbf{M}^*\mathbf{M}$, so the two have the same eigenvalues and Definition 12.8.1 reads the same singular values off them. Hence by Theorem 15.3.3 (c),

$$\|(\mathbf{A}^*\mathbf{A})^{-1}\| = \sigma_n^{-2}, \qquad \|(\mathbf{A}^*\mathbf{A})^{-1}\mathbf{A}^*\| = \sigma_n^{-1}.$$

Applying these to $(*)$ with Theorem 15.3.2 (a),

$$\|\mathbf{x}'(0)\| \;\le\; \frac{\|\mathbf{E}\|\,\|\mathbf{r}\|}{\sigma_n^2} \;+\; \frac{\|\mathbf{E}\|\,\|\mathbf{x}\|}{\sigma_n} \;+\; \frac{\|\mathbf{f}\|}{\sigma_n}.$$

Divide by $\|\mathbf{x}\|$ and use $\|\mathbf{A}\| = \sigma_1$ (Theorem 15.3.3 (c)) and $\kappa_2(\mathbf{A}) = \sigma_1/\sigma_n$ (Definition 15.8.1). The middle term becomes $\|\mathbf{E}\|/\sigma_n = \kappa_2(\mathbf{A})\varepsilon_{\mathbf{A}}$ exactly. For the other two, note that $\sigma_1\|\mathbf{x}\| \ge \|\mathbf{A}\mathbf{x}\| = \|\mathbf{b}\|\cos\theta$, so

$$\frac{\|\mathbf{r}\|}{\sigma_1\|\mathbf{x}\|} \le \frac{\|\mathbf{b}\|\sin\theta}{\|\mathbf{b}\|\cos\theta} = \tan\theta, \qquad \frac{\|\mathbf{b}\|}{\sigma_1\|\mathbf{x}\|} \le \frac{1}{\cos\theta}.$$

Therefore

$$\frac{\|\mathbf{E}\|\|\mathbf{r}\|}{\sigma_n^2\|\mathbf{x}\|} = \frac{\sigma_1^2}{\sigma_n^2}\cdot\frac{\|\mathbf{E}\|}{\sigma_1}\cdot\frac{\|\mathbf{r}\|}{\sigma_1\|\mathbf{x}\|} \le \kappa_2(\mathbf{A})^2\varepsilon_{\mathbf{A}}\tan\theta,$$
$$\frac{\|\mathbf{f}\|}{\sigma_n\|\mathbf{x}\|} = \frac{\sigma_1}{\sigma_n}\cdot\frac{\|\mathbf{f}\|}{\|\mathbf{b}\|}\cdot\frac{\|\mathbf{b}\|}{\sigma_1\|\mathbf{x}\|} \le \frac{\kappa_2(\mathbf{A})\varepsilon_{\mathbf{b}}}{\cos\theta}.$$

Adding the three estimates gives the stated bound. This proves the theorem.

■

What is linearized, and what is not. The theorem itself is exact: it bounds a derivative, and no term has been discarded. What is an approximation is the use one makes of it. Reading it as

$$\frac{\|\Delta\mathbf{x}\|}{\|\mathbf{x}\|} \;\lesssim\; \Big[\kappa_2(\mathbf{A})\big(1+\tfrac{1}{\cos\theta}\big) + \kappa_2(\mathbf{A})^2\tan\theta\Big]\,\varepsilon \tag{23.3.2}$$

for data perturbed by $\|\Delta\mathbf{A}\| \le \varepsilon\|\mathbf{A}\|$ and $\|\Delta\mathbf{b}\| \le \varepsilon\|\mathbf{b}\|$ drops a remainder of size $O(\varepsilon^2)$, exactly as Theorem 15.8.3 (b) drops the factor $1/(1-r)$. For the $\varepsilon \approx 10^{-16}$ of the floating-point model that remainder is invisible, and every statement below that carries a $\lesssim$ is a statement of this kind.

Two readings of the bound matter.

- **When the residual is zero**, $\theta = 0$ and the bound is $2\kappa_2(\mathbf{A})\varepsilon$: the least-squares problem is exactly as sensitive as a square linear system with the same condition number. A square invertible $\mathbf{A}$ is always this case, and Theorem 15.8.3 is recovered.
- **When the residual is large**, the term $\kappa_2(\mathbf{A})^2\tan\theta$ dominates the bound, and what it measures belongs to the *problem*: no algorithm can return an answer more accurate than data of that quality determine. This is the sentence Chapter 15 §08 promised, where the least-squares problem was said to have "a sensitivity that depends on $\kappa_2(\mathbf{A})$, on the residual $\|\mathbf{A}\mathbf{x}^+ - \mathbf{b}\|$ and on the angle between $\mathbf{b}$ and $\operatorname{col}(\mathbf{A})$". Exercise (C1: The squared term is attained) exhibits data on which the $\kappa_2(\mathbf{A})^2\varepsilon_{\mathbf{A}}\tan\theta$ term is attained exactly, so it

is not an artifact of the estimates.

Quick check. Take $m = n$ with $\mathbf{A}$ invertible. What does Eq. 23.3.1 give for θ, and what does Eq. 23.3.2 reduce to? Compare with Theorem 15.8.3.

Solution. For an invertible square $\mathbf{A}$ the system $\mathbf{Az} = \mathbf{b}$ is consistent, so its least-squares solution has residual $\mathbf{r} = \mathbf{0}$ and Eq. 23.3.1 gives $\sin\theta = 0$, that is $\theta = 0$. Then $\cos\theta = 1$ and $\tan\theta = 0$, and Eq. 23.3.2 reads $\|\Delta\mathbf{x}\|/\|\mathbf{x}\| \lesssim 2\kappa(\mathbf{A})\varepsilon$. That is Theorem 15.8.3 (a) and (b) added together, with the factor $1/(1-r)$ replaced by the $O(\varepsilon^2)$ that the linearization discards. The square case carries no κ^2 at all.

23.3.2 Two routes, and the digits they lose

The problem is measured; now the two algorithms. Both are run in the arithmetic of Definition 23.1.1, with u the unit roundoff and $\gamma_k = ku/(1-ku)$ the constant of Lemma 23.1.1.

The **normal-equation route** forms $\mathbf{C} = \mathrm{fl}(\mathbf{A}^*\mathbf{A})$ and $\mathbf{d} = \mathrm{fl}(\mathbf{A}^*\mathbf{b})$ entry by entry as inner products, then solves $\mathbf{Cz} = \mathbf{d}$. The matrix it hands to the solver need **not** be positive definite. The exact $\mathbf{A}^*\mathbf{A}$ is: $\mathbf{x}^*\mathbf{A}^*\mathbf{Ax} = \|\mathbf{Ax}\|^2 > 0$ for $\mathbf{x} \neq \mathbf{0}$, the columns of $\mathbf{A}$ being independent. The computed $\mathbf{C}$ is Hermitian, only one triangle of it being formed, but its eigenvalues are those of $\mathbf{A}^*\mathbf{A}$ displaced by the rounding, and the smallest of them, $\sigma_n(\mathbf{A})^2$, can be displaced past 0 — Example (A matrix where one route survives and the other does not) below exhibits a $\mathbf{C}$ that comes out singular, on which the Cholesky factorization of Theorem 12.2.3 fails outright. **When $\mathbf{C}$ is positive definite** — which it is while the rounding stays below $\sigma_n(\mathbf{A})^2$ — Cholesky, and the analysis Section 2 gives it, apply.

The cost is mn^2 flops to form the product — there are $\frac{1}{2}n(n+1)$ entries to compute, each an inner product of length m costing $2m$ flops — plus $\frac{1}{3}n^3$ for the factorization (Proposition 23.2.3 (c)) and $2n^2$ for the two triangular solves. The **QR route** never forms that product: it computes a factorization $\mathbf{A} = \mathbf{QR}$ by reflections (Theorem 10.8.4), applies $\mathbf{Q}^*$ to $\mathbf{b}$, and solves the triangular system $\mathbf{Rx} = \mathbf{Q}^*\mathbf{b}$ by back substitution, which Theorem 23.2.5 showed to be backward stable. Its cost is $2mn^2 - \frac{2}{3}n^3$ flops by a sum of the same kind as Proposition 23.2.3, which we do not write out: about twice the first when $m \gg n$.

The rule of thumb of Theorem 23.1.3 says: forward relative error $\leq$ condition number $\times$ backward relative error. The two routes solve *different problems*, and that is the whole story. The first solves a square linear system whose matrix is $\mathbf{A}^*\mathbf{A}$, of condition number $\kappa_2(\mathbf{A})^2$ by Theorem 15.8.4. The second solves the least-squares problem itself, of sensitivity given by Theorem 23.3.1. Here is the comparison. Part (a) is Theorem 23.1.3 applied to the system $\mathbf{A}^*\mathbf{Ax} = \mathbf{A}^*\mathbf{b}$, except that here the right-hand side is perturbed as well, so we give the short direct argument instead of appealing to it.

Theorem 23.3.2 — The Normal Equations Lose Twice the Digits

Let $\mathbf{A} \in M_{m\times n}(F)$ have rank $n \leq m$, let $\mathbf{b} \neq \mathbf{0}$, let $\mathbf{x}$ be the least-squares solution and let $\theta < \pi/2$ be as in Eq. 23.3.1. Work in the model of Definition 23.1.1, and suppose $mu \leq \frac{1}{2}$.

(a) **(Normal equations.)** Suppose $\mathbf{C} = \mathrm{fl}(\mathbf{A}^*\mathbf{A})$ and $\mathbf{d} = \mathrm{fl}(\mathbf{A}^*\mathbf{b})$ are formed by inner products, and that $\mathbf{Cz} = \mathbf{d}$ is then solved by a method that is backward

stable in the sense of Definition 23.1.3, so that the computed $\widehat{\mathbf{x}}$ satisfies $(\mathbf{C}+\Delta\mathbf{C})\widehat{\mathbf{x}} = \mathbf{d}+\Delta\mathbf{d}$ with $\|\Delta\mathbf{C}\| \le c_s u\|\mathbf{C}\|$ and $\|\Delta\mathbf{d}\| \le c_s u\|\mathbf{d}\|$. Then there is a constant c, depending only on m, n and c_s and of size $O(mn)$, such that if $c\,u\,\kappa_2(\mathbf{A})^2 < 1$ then

$$\frac{\|\widehat{\mathbf{x}}-\mathbf{x}\|}{\|\mathbf{x}\|} \;\le\; \frac{c\,u\,\kappa_2(\mathbf{A})^2\big(1+\frac{1}{\cos\theta}\big)}{1-c\,u\,\kappa_2(\mathbf{A})^2}.$$

The bound carries $\kappa_2(\mathbf{A})^2$ **even when the residual is zero**.

(b) **(A backward stable least-squares solver.)** Suppose instead that $\widehat{\mathbf{x}}$ is the exact least-squares solution of $(\mathbf{A}+\Delta\mathbf{A})\mathbf{z} = \mathbf{b}+\Delta\mathbf{b}$ for some $\Delta\mathbf{A}, \Delta\mathbf{b}$ with $\|\Delta\mathbf{A}\| \le c'u\|\mathbf{A}\|$ and $\|\Delta\mathbf{b}\| \le c'u\|\mathbf{b}\|$. Then, to first order in u as in Eq. 23.3.2,

$$\frac{\|\widehat{\mathbf{x}}-\mathbf{x}\|}{\|\mathbf{x}\|} \;\lesssim\; c'u\Big[\kappa_2(\mathbf{A})\big(1+\tfrac{1}{\cos\theta}\big) + \kappa_2(\mathbf{A})^2\tan\theta\Big].$$

Idea. For (a), the two sources of error — forming the product, and solving the system — are both perturbations of the *exact* normal equations, and both are bounded by a constant times $u\|\mathbf{A}\|^2$ or $u\|\mathbf{A}\|\|\mathbf{b}\|$. Subtract the exact equations from the perturbed ones and multiply by $(\mathbf{A}^*\mathbf{A})^{-1}$, whose norm is σ_n^{-2}: the two factors of σ_1/σ_n appear there and nowhere else. The one nuisance is that the estimate produces $\|\widehat{\mathbf{x}}\|$ rather than $\|\mathbf{x}\|$; subadditivity of the norm (Corollary 10.1.6) trades one for the other at the cost of the denominator, exactly as in Theorem 15.8.3 (b). For (b) there is nothing to do: the hypothesis says the computed answer is the exact answer to perturbed data, which is what Theorem 23.3.1 measures.

Proof. (a). We argue over $\mathbb{R}$, the field in which Theorem 23.1.2 is stated; over $\mathbb{C}$ each complex multiplication and addition is a bounded number of real ones, and the same argument gives the same bound with a larger constant c. Write $\mathbf{a}_1,\dots,\mathbf{a}_n$ for the columns of $\mathbf{A}$, so that $(\mathbf{A}^*\mathbf{A})_{ij} = \mathbf{a}_i^*\mathbf{a}_j$ and $(\mathbf{A}^*\mathbf{b})_i = \mathbf{a}_i^*\mathbf{b}$, each an inner product of length m. By Theorem 23.1.2, $\mathrm{fl}(\mathbf{a}_i^*\mathbf{a}_j) = (\mathbf{a}_i+\Delta\mathbf{a})^*\mathbf{a}_j$ with $|\Delta\mathbf{a}| \le \gamma_m|\mathbf{a}_i|$ entrywise, so

$$\big|c_{ij} - \mathbf{a}_i^*\mathbf{a}_j\big| \le \gamma_m|\mathbf{a}_i|^{\top}|\mathbf{a}_j| \le \gamma_m\|\mathbf{a}_i\|\|\mathbf{a}_j\|,$$

the last step by Cauchy–Schwarz (Theorem 10.1.5). Summing squares and using $\|\mathbf{M}\| \le \|\mathbf{M}\|_F$ — true because $\|\mathbf{M}\|_F^2 = \mathrm{tr}(\mathbf{M}^*\mathbf{M})$ is the sum of the eigenvalues of $\mathbf{M}^*\mathbf{M}$, hence of the $\sigma_i(\mathbf{M})^2$, while $\|\mathbf{M}\| = \sigma_1(\mathbf{M})$ by Theorem 15.3.3 (c) —

$$\|\mathbf{C}-\mathbf{A}^*\mathbf{A}\| \le \|\mathbf{C}-\mathbf{A}^*\mathbf{A}\|_F \le \gamma_m\Big(\sum_i\|\mathbf{a}_i\|^2\Big) = \gamma_m\|\mathbf{A}\|_F^2 \le n\gamma_m\|\mathbf{A}\|^2.$$

The same argument on $\mathbf{d}$ gives $\|\mathbf{d}-\mathbf{A}^*\mathbf{b}\| \le \gamma_m\|\mathbf{b}\|\|\mathbf{A}\|_F \le \sqrt{n}\,\gamma_m\|\mathbf{A}\|\|\mathbf{b}\|$.

Now add the solver's backward error. Put $\mathbf{\Delta} = (\mathbf{C}+\Delta\mathbf{C})-\mathbf{A}^*\mathbf{A}$ and $\mathbf{h} = (\mathbf{d}+\Delta\mathbf{d})-\mathbf{A}^*\mathbf{b}$. Since $\|\mathbf{C}\| \le (1+n\gamma_m)\|\mathbf{A}\|^2$ and $\|\mathbf{d}\| \le (1+\sqrt{n}\gamma_m)\|\mathbf{A}\|\|\mathbf{b}\|$,

$$\|\mathbf{\Delta}\| \le c\,u\|\mathbf{A}\|^2, \qquad \|\mathbf{h}\| \le c\,u\|\mathbf{A}\|\|\mathbf{b}\|,$$

with $c = 2nm + c_s(1+2nm)$ serving, say, since the hypothesis $mu \le \frac{1}{2}$ gives $\gamma_m \le 2mu$, and $\sqrt{n} \le n$.

The exact solution satisfies $\mathbf{A}^*\mathbf{A}\mathbf{x} = \mathbf{A}^*\mathbf{b}$ and the computed one satisfies $(\mathbf{A}^*\mathbf{A}+\boldsymbol{\Delta})\widehat{\mathbf{x}} = \mathbf{A}^*\mathbf{b}+\mathbf{h}$. Subtracting,

$$\mathbf{A}^*\mathbf{A}(\widehat{\mathbf{x}}-\mathbf{x}) = \mathbf{h}-\boldsymbol{\Delta}\widehat{\mathbf{x}}, \qquad \|\widehat{\mathbf{x}}-\mathbf{x}\| \le \sigma_n^{-2}\big(c\,u\|\mathbf{A}\|\|\mathbf{b}\| + c\,u\|\mathbf{A}\|^2\|\widehat{\mathbf{x}}\|\big),$$

using $\|(\mathbf{A}^*\mathbf{A})^{-1}\| = \sigma_n^{-2}$ from the proof of Theorem 23.3.1. Divide by $\|\mathbf{x}\|$, write $\rho = \|\widehat{\mathbf{x}}-\mathbf{x}\|/\|\mathbf{x}\|$, and use $\sigma_1\|\mathbf{x}\| \ge \|\mathbf{b}\|\cos\theta$ together with $\|\widehat{\mathbf{x}}\| \le \|\mathbf{x}\|(1+\rho)$:

$$\rho \;\le\; c\,u\,\kappa_2(\mathbf{A})^2\Big(\frac{1}{\cos\theta}+1+\rho\Big).$$

Since $c\,u\,\kappa_2(\mathbf{A})^2 < 1$ we may collect the ρ terms and divide, which gives the stated bound. Nothing in the argument used $\mathbf{r}$, so it holds for $\theta = 0$ as it stands.

(b). By hypothesis $\widehat{\mathbf{x}} = \mathbf{x}(1)$ for the family of Theorem 23.3.1 with $\mathbf{E} = \Delta\mathbf{A}$ and $\mathbf{f} = \Delta\mathbf{b}$, and $\varepsilon_{\mathbf{A}}, \varepsilon_{\mathbf{b}} \le c'u$. The stated bound is Eq. 23.3.2 for that family. This proves the theorem.

■

In digits. A relative error of η means about $\log_{10}(1/\eta)$ correct decimal digits, and an arithmetic with unit roundoff $u \approx 10^{-16}$ offers about 16 of them. Part (a) says the normal-equation route returns an answer with relative error about $u\kappa_2(\mathbf{A})^2$: it **loses about** $2\log_{10}\kappa_2(\mathbf{A})$ **digits**, whatever the residual. Part (b) says a backward stable least-squares solver returns an answer with relative error about $u\kappa_2(\mathbf{A})$ when the residual is small, and so **loses about** $\log_{10}\kappa_2(\mathbf{A})$ **digits**.

The comparison Chapter 15 §08 left open has two halves, and only one of them is settled here. The half that is proved is the *implication*: **a** backward stable least-squares solver loses about $\log_{10}\kappa_2(\mathbf{A})$ digits, while forming $\mathbf{A}^*\mathbf{A}$ loses about twice that — and part (a), which carries no stability hypothesis at all, is unconditional.

The half that is **not** proved is that the reflection route of Chapter 10 §08 supplies such a solver. That is the accumulated statement of the remark after Theorem 23.3.3 below, which this book records with credit and does not prove; what Theorem 23.3.3 itself proves is the backward stability of **one** reflection. A further qualification is the content of the next warning.

Warning. **The two-versus-one comparison is a small-residual statement, and the reason is not symmetric.** For a large residual the bound in (b) also carries a $\kappa_2(\mathbf{A})^2$, through the term $\kappa_2(\mathbf{A})^2\tan\theta$. The difference is *where that square comes from.* In (b) it is the sensitivity of the problem, certified by Theorem 23.3.1, and no method whatever can avoid it. In (a) it is manufactured by the algorithm: it is there when $\theta = 0$, where the problem's own sensitivity is only $\kappa_2(\mathbf{A})$. So the honest form of the comparison is: **a backward stable method loses what the problem costs; forming $\mathbf{A}^*\mathbf{A}$ loses $\kappa_2(\mathbf{A})$ times more than that whenever $\tan\theta \lesssim 1/\kappa_2(\mathbf{A})$, and never less.**

Example. (A matrix where one route survives and the other does not)

Let $\varepsilon > 0$ and

$$\mathbf{A} = \begin{pmatrix} 1 & 1 \\ \varepsilon & 0 \\ 0 & \varepsilon \end{pmatrix}, \qquad \mathbf{b} = \begin{pmatrix} 1 \\ 2\varepsilon \\ -\varepsilon \end{pmatrix}.$$

Find $\kappa_2(\mathbf{A})$, the exact least-squares solution and the residual. Then run both routes in the model with $u = 2^{-53}$, for $\varepsilon = 10^{-6}$ and for $\varepsilon = 10^{-9}$, and compare.

Solution. Exact data. $\mathbf{A}^\top\mathbf{A} = \begin{pmatrix} 1+\varepsilon^2 & 1 \\ 1 & 1+\varepsilon^2 \end{pmatrix}$, which sends $(1,1)$ to $(2+\varepsilon^2)(1,1)$ and $(1,-1)$ to $\varepsilon^2(1,-1)$. So its eigenvalues are $2+\varepsilon^2$ and ε^2, the singular values of $\mathbf{A}$ are $\sqrt{2+\varepsilon^2}$ and ε, and

$$\kappa_2(\mathbf{A}) = \frac{\sqrt{2+\varepsilon^2}}{\varepsilon}.$$

Also $\mathbf{A}(2,-1) = (2-1,\ 2\varepsilon,\ -\varepsilon) = \mathbf{b}$, so the system is **consistent**: the least-squares solution is $\mathbf{x} = (2,-1)$ exactly, the residual is $\mathbf{r} = \mathbf{0}$, and $\theta = 0$. By Theorem 23.3.1 the problem's sensitivity is exactly $2\kappa_2(\mathbf{A})$ — there is no κ_2^2 in the problem at all.

$\varepsilon = 10^{-6}$. Here $\kappa_2(\mathbf{A}) = 1.4142136\cdot 10^6$, so $u\kappa_2(\mathbf{A}) = 1.6\cdot 10^{-10}$ and $u\kappa_2(\mathbf{A})^2 = 2.2\cdot 10^{-4}$. Forming the product rounds $1+\varepsilon^2 = 1+10^{-12}$ to 1.0000000000010000889; the last four digits are the rounding, and they are a relative perturbation of about 10^{-4} in the *difference* ε^2 that carries the small eigenvalue. Cholesky and the two triangular solves then return

$$\widehat{\mathbf{x}} = (1.99983348134991,\ -0.99983348134991),$$

a relative error of $\|\widehat{\mathbf{x}}-\mathbf{x}\|/\|\mathbf{x}\| = 1.05\cdot 10^{-4}$ — about four correct digits out of sixteen, and within a factor of 2 of the bound $u\kappa_2(\mathbf{A})^2 = 2.2\cdot 10^{-4}$. (Entry by entry the relative errors are $8.3\cdot 10^{-5}$ and $1.7\cdot 10^{-4}$; it is the 2-norm figure that the theorem bounds.) The reflection route returns $(2,-1)$, every digit correct.

$\varepsilon = 10^{-9}$. Now $\kappa_2(\mathbf{A}) = 1.4142136\cdot 10^9$ and $u\kappa_2(\mathbf{A})^2 = 222$, so part (a) promises nothing at all — and nothing is what it delivers. Since $\varepsilon^2 = 10^{-18}$ is below u, the computed product is

$$\mathbf{C} = \mathrm{fl}(\mathbf{A}^\top\mathbf{A}) = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix},$$

a **singular** matrix: its Cholesky factorization (Theorem 12.2.3) fails at the second pivot, and the route cannot even be run. The reflection route again returns $(2,-1)$.

The bound is an upper bound. For $\varepsilon = 10^{-9}$ the reflection route is entitled to lose $\log_{10}\kappa_2(\mathbf{A}) \approx 9$ digits and in fact loses none: the answer is exactly representable and the arithmetic happens to reach it. Part (b) is a worst case over perturbations, as Theorem 15.8.3 was. Part (a) is an upper bound too, and it is not attained exactly either; what this example shows is that it is not a pessimistic one — the normal-equation route does lose its $2\log_{10}\kappa_2(\mathbf{A})$ digits here, to within a factor of 2 in the error.

Warning. **Forming $\mathbf{A}^*\mathbf{A}$ is not forbidden, it is limited.** If $\kappa_2(\mathbf{A}) = 10^3$ then $u\kappa_2(\mathbf{A})^2 \approx 10^{-10}$, and the normal equations return ten correct digits for half the arithmetic. The rule is quantitative, not moral: the route is safe exactly while $u\kappa_2(\mathbf{A})^2$ is small enough for the purpose, and it collapses — as Example (A matrix where one route survives and the other does not) shows — once $\kappa_2(\mathbf{A})$ approaches $u^{-1/2} \approx 10^8$. What is never acceptable is forming the product without knowing which side of that threshold one is on.

23.3.3 Why the reflection route is the stable one

Part (b) above assumed a backward stable least-squares solver. That hypothesis has to be earned, and earning it is what Chapter 10 §08's reflections are for. The claim to be supported is: applying a Householder reflection by the formula

$$\mathbf{H}_{\mathbf{w}}\mathbf{v} = \mathbf{v} - \frac{2\langle \mathbf{v}, \mathbf{w}\rangle}{\|\mathbf{w}\|^2}\,\mathbf{w} \tag{23.3.3}$$

of Chapter 10 §08 — **applying it, never forming the matrix** — commits a backward error of size u, with no dependence on the conditioning of anything. Here is that statement, proved.

Theorem 23.3.3 — Backward Stability of One Reflection

Work in the model of Definition 23.1.1 over $\mathbb{R}$, and suppose $(10m+16)u \le \frac{1}{4}$. Let $\mathbf{w} \in \mathbb{R}^m$ be non-zero and let $\mathbf{H} = \mathbf{H}_{\mathbf{w}}$ be the reflection of Definition 10.8.1, and suppose $\mathbf{w}$ and the input are stored exactly.

(a) For $\mathbf{v} \in \mathbb{R}^m$, let $\widehat{\mathbf{y}}$ be the vector computed from $\mathbf{v}$ and $\mathbf{w}$ by Eq. 23.3.3. Then

$$\widehat{\mathbf{y}} = \mathbf{H}(\mathbf{v} + \Delta\mathbf{v}), \qquad \|\Delta\mathbf{v}\|_2 \le (10m+16)\,u\,\|\mathbf{v}\|_2.$$

(b) For $\mathbf{A} \in M_{m\times n}(\mathbb{R})$, let $\widehat{\mathbf{B}}$ be the matrix whose columns are computed from those of $\mathbf{A}$ in this way. Then

$$\widehat{\mathbf{B}} = \mathbf{H}(\mathbf{A} + \Delta\mathbf{A}), \qquad \|\Delta\mathbf{A}\|_F \le (10m+16)\,u\,\|\mathbf{A}\|_F.$$

Idea. Three quantities are computed before anything is subtracted: $\|\mathbf{w}\|^2$, the inner product $\langle \mathbf{v}, \mathbf{w}\rangle$, and their quotient β. Each is an inner product or a division, so Theorem 23.1.2 and Lemma 23.1.1 bound them at once, and the crude estimate $|\beta| \le 2\|\mathbf{v}\|/\|\mathbf{w}\|$ — which is Cauchy–Schwarz and nothing more — keeps every error proportional to $\|\mathbf{v}\|$, not to $\|\mathbf{v}\|/\|\mathbf{w}\|$. Then the forward error $\|\widehat{\mathbf{y}} - \mathbf{H}\mathbf{v}\|$ is converted into a backward error for free, because $\mathbf{H}$ is an isometry and its own inverse: $\Delta\mathbf{v} = \mathbf{H}(\widehat{\mathbf{y}} - \mathbf{H}\mathbf{v})$ has exactly the same length. Part (b) is part (a) column by column, since the Frobenius norm adds the columns in squares.

Proof. (a). Write $\nu = \|\mathbf{w}\|_2$, $\beta = 2\langle \mathbf{v}, \mathbf{w}\rangle/\nu^2$, so that $\mathbf{H}\mathbf{v} = \mathbf{v} - \beta\mathbf{w}$, and abbreviate $\gamma_k = ku/(1-ku)$. The hypothesis $(10m+16)u \le \frac{1}{4}$ gives in particular $(m+2)u \le \frac{1}{4}$, so $\gamma_k \le \frac{4}{3}ku \le \frac{1}{3}$ for every $k \le m+2$.

Step 1: the two inner products. The computed $s = \mathrm{fl}(\mathbf{w}^*\mathbf{w})$ is a sum of m non-negative terms w_i^2, each carrying at most m rounding factors, so by Lemma 23.1.1 $s = \sum_i w_i^2(1+\theta_i)$ with $|\theta_i| \le \gamma_m$; as every $w_i^2 \ge 0$ this gives $s = \nu^2(1+\theta)$ with $|\theta| \le \gamma_m$. By Theorem 23.1.2 the computed $p = \mathrm{fl}(\mathbf{v}^*\mathbf{w})$ satisfies $p = \langle \mathbf{v}, \mathbf{w}\rangle + \eta$ with

$$|\eta| \le \gamma_m |\mathbf{v}|^{\top}|\mathbf{w}| \le \gamma_m \|\mathbf{v}\|\nu,$$

by Cauchy–Schwarz (Theorem 10.1.5).

Step 2: the coefficient. The computed $\widehat{\beta}$ is $(2p/s)$ times two rounding factors, so $\widehat{\beta} = (2p/s)(1+\theta_2)$ with $|\theta_2| \le \gamma_2$, by Lemma 23.1.1. Writing $2p/s = (\beta+\zeta)/(1+\theta)$

with $\zeta = 2\eta/\nu^2$ and $|\zeta| \le 2\gamma_m\|\mathbf{v}\|/\nu$,

$$\left|\frac{1+\theta_2}{1+\theta} - 1\right| \le \frac{\gamma_m + \gamma_2}{1-\gamma_m} \le \tfrac{3}{2}(\gamma_m + \gamma_2) \le 2(m+2)u,$$

using $1 - \gamma_m \ge \frac{2}{3}$ and $\gamma_k \le \frac{4}{3}ku$; in particular the factor itself has modulus at most 2. Since $|\beta| \le 2\|\mathbf{v}\|/\nu$ by Cauchy–Schwarz,

$$|\widehat{\beta} - \beta| \le |\beta| \cdot 2(m+2)u + 2|\zeta| \le \frac{\|\mathbf{v}\|}{\nu}\big(4(m+2)u + 6mu\big) \le K\,u\,\frac{\|\mathbf{v}\|}{\nu},$$

with $K = 10m + 8$. In particular $|\widehat{\beta}| \le 3\|\mathbf{v}\|/\nu$, since $Ku \le (10m+16)u \le \frac{1}{4}$.

Step 3: the subtraction. Entry i is computed as $\widehat{y}_i = (v_i - \widehat{\beta}w_i(1+\delta_i))(1+\delta_i')$ with $|\delta_i|, |\delta_i'| \le u$. Subtracting $(\mathbf{Hv})_i = v_i - \beta w_i$ and regrouping,

$$\widehat{y}_i - (\mathbf{Hv})_i = (v_i - \widehat{\beta}w_i)\delta_i' + (\beta - \widehat{\beta})w_i - \widehat{\beta}w_i\delta_i(1+\delta_i').$$

Take 2-norms over i, one term at a time. The first is at most $u(\|\mathbf{v}\| + |\widehat{\beta}|\nu) \le 4u\|\mathbf{v}\|$; the second is $|\beta - \widehat{\beta}|\nu \le Ku\|\mathbf{v}\|$; the third is at most $|\widehat{\beta}|\nu\,u(1+u) \le 4u\|\mathbf{v}\|$. Hence

$$\|\widehat{\mathbf{y}} - \mathbf{Hv}\|_2 \le (K+8)u\|\mathbf{v}\|_2 = (10m+16)u\|\mathbf{v}\|_2.$$

Step 4: forward to backward. Put $\Delta\mathbf{v} = \mathbf{H}(\widehat{\mathbf{y}} - \mathbf{Hv})$. Then $\mathbf{H}(\mathbf{v} + \Delta\mathbf{v}) = \mathbf{Hv} + \mathbf{H}^2(\widehat{\mathbf{y}} - \mathbf{Hv}) = \widehat{\mathbf{y}}$ by Proposition 10.8.2 (b), and $\|\Delta\mathbf{v}\|_2 = \|\widehat{\mathbf{y}} - \mathbf{Hv}\|_2$ because $\mathbf{H}$ is unitary (Proposition 10.8.2 (c)). This is (a).

(b). Apply (a) to each column $\mathbf{a}_j$, obtaining $\Delta\mathbf{a}_j$ with $\|\Delta\mathbf{a}_j\|_2 \le (10m+16)u\|\mathbf{a}_j\|_2$, and let $\Delta\mathbf{A}$ have these columns. Then $\widehat{\mathbf{B}} = \mathbf{H}(\mathbf{A} + \Delta\mathbf{A})$ column by column, and squaring and summing over j gives $\|\Delta\mathbf{A}\|_F \le (10m+16)u\|\mathbf{A}\|_F$. This proves the theorem.

■

The constants are crude on purpose; what matters is their shape. **The bound is a multiple of u and of m, and of nothing else.** No condition number appears, and none can: a reflection is an isometry, so it neither stretches nor shrinks, and there is no small quantity anywhere for a rounding error to be measured against.

Remark. **What the accumulation says, and that we do not prove it.** Running $\min(n, m-1)$ reflections as in Theorem 10.8.4, one obtains computed $\widehat{\mathbf{R}}$ and stored reflection vectors. The classical theorem — due to Wilkinson, and proved by inducting the argument above over the reflections while tracking how the perturbations compose — states that there is an **exactly** unitary $\widetilde{\mathbf{Q}} \in M_m(\mathbb{R})$, not in general the product of the computed reflections, with

$$\widetilde{\mathbf{Q}}\,\widehat{\mathbf{R}} = \mathbf{A} + \Delta\mathbf{A}, \qquad \|\Delta\mathbf{A}\|_F \le c(m,n)\,u\,\|\mathbf{A}\|_F,$$

and that the resulting least-squares solution is the exact solution of a problem with data perturbed by $O(u)$ — the hypothesis of Theorem 23.3.2 (b). **This accumulated statement is not proved here**, and nothing in this book depends on it: every theorem above either proves its own case or carries backward stability as a stated hypothesis. The induction is not deep, but it is long, and the honest thing is to say so.

23.3.4 What goes wrong with Gram–Schmidt

Chapter 10 §02 warned that "the classical process is numerically fragile" and promised that this chapter would say why the reflection route is the stable one. Half of the answer is Theorem 23.3.3. The other half is what the Gram–Schmidt recursion of Theorem 10.2.2 does instead.

The recursion subtracts from $\mathbf{a}_k$ its components along the vectors already produced. When the columns are nearly dependent, what is left is a small difference of large quantities, and the leading digits cancel, exactly as in the subtraction of nearly equal numbers examined in Section 1. The computed $\mathbf{q}_k$ is then a unit vector in a noticeably wrong direction, and, worse, the error is not random: it is inherited by every later step. The measured consequence is a loss of *orthogonality*: the computed $\widehat{\mathbf{Q}}$ satisfies $\widehat{\mathbf{Q}}^{\top}\widehat{\mathbf{Q}} \neq \mathbf{I}$ by an amount that grows with $\kappa_2(\mathbf{A})$. The classical analyses, which we state with credit and **do not prove here**, say how fast:

- for the **classical** process, $\|\widehat{\mathbf{Q}}^{\top}\widehat{\mathbf{Q}} - \mathbf{I}\|$ is of order $u\,\kappa_2(\mathbf{A})^2$ (Kielbasinski; Giraud, Langou and Rozloznik);
- for the **modified** process, in which each new vector is projected against the $\mathbf{q}_i$ one at a time as it is formed rather than all at once from the original $\mathbf{a}_k$, it is of order $u\,\kappa_2(\mathbf{A})$ (Bjorck);
- for the reflection route it is of order u, independently of $\kappa_2(\mathbf{A})$, which is the content of Theorem 23.3.3.

Example. (Three columns and three answers)

Let $\varepsilon = 10^{-6}$ and

$$\mathbf{A} = \begin{pmatrix} 1 & 1 & 1 \\ \varepsilon & 0 & 0 \\ 0 & \varepsilon & 0 \end{pmatrix}.$$

Show that $\kappa_2(\mathbf{A}) = 3/\varepsilon + O(\varepsilon)$, then run the classical and the modified recursion in the model with $u = 2^{-53}$ and compare the inner products of the computed vectors.

Solution. The condition number. $\mathbf{A}^{\top}\mathbf{A} = \begin{pmatrix} 1+\varepsilon^2 & 1 & 1 \\ 1 & 1+\varepsilon^2 & 1 \\ 1 & 1 & 1 \end{pmatrix}$. Its characteristic polynomial factors as

$$\det(t\mathbf{I} - \mathbf{A}^{\top}\mathbf{A}) = (t - \varepsilon^2)\big(t^2 - (3+\varepsilon^2)t + \varepsilon^2\big),$$

as one checks by expanding both sides. The quadratic has roots $t_{\pm}$ with $t_+ t_- = \varepsilon^2$ and $t_+ + t_- = 3 + \varepsilon^2$, so $t_+ = 3 + O(\varepsilon^2)$ and $t_- = \varepsilon^2/3 + O(\varepsilon^4)$. Hence $\sigma_1 = \sqrt{3} + O(\varepsilon^2)$ and $\sigma_3 = \varepsilon/\sqrt{3} + O(\varepsilon^3)$, and

$$\kappa_2(\mathbf{A}) = \frac{\sqrt{3}}{\varepsilon/\sqrt{3}} + O(\varepsilon) = \frac{3}{\varepsilon} + O(\varepsilon) = 3.000000 \cdot 10^{6}.$$

So $u\kappa_2(\mathbf{A}) = 3.3 \cdot 10^{-10}$ and $u\kappa_2(\mathbf{A})^2 = 1.0 \cdot 10^{-3}$.

The computed vectors. Both recursions produce the same $\mathbf{q}_1$ and $\mathbf{q}_2$, with $\langle \mathbf{q}_1, \mathbf{q}_2 \rangle = 6.3 \cdot 10^{-11}$: that is the unavoidable $u\kappa_2(\mathbf{A})$, and it is already five to six digits worse than u, being larger by a factor of $5.7 \cdot 10^{5}$. The two differ at the third step, which is where the cancellation bites:

$$\begin{aligned} \text{classical:} \quad & \langle \mathbf{q}_2, \mathbf{q}_3 \rangle = -8.89 \cdot 10^{-5}, \\ \text{modified:} \quad & \langle \mathbf{q}_2, \mathbf{q}_3 \rangle = 0. \end{aligned}$$

> The classical figure is within a factor of 12 of $u\kappa_2(\mathbf{A})^2 = 1.0 \cdot 10^{-3}$; the modified figure is at the level of $u\kappa_2(\mathbf{A})$ or below. Two vectors at inner product $9 \cdot 10^{-5}$ are at about 89.995 degrees to each other, and a basis that is orthonormal only to five digits is worth five digits in everything computed from it.

23.3.5 The sign in the reflection, quantified

Chapter 10 §08 chose $\mathbf{w} = \mathbf{x} + \alpha\|\mathbf{x}\|\mathbf{e}_1$ rather than $\mathbf{w}' = \mathbf{x} - \alpha\|\mathbf{x}\|\mathbf{e}_1$, where α is the phase of x_1, and said: "Chapter 23 quantifies the loss; the summary here is that both signs are correct mathematics and only one is correct arithmetic." Here is the quantity.

Take $\mathbf{x} \in \mathbb{R}^m$ non-zero with $x_1 > 0$, so $\alpha = 1$, and write $\widetilde{\mathbf{x}} = (x_2, \dots, x_m)$. Expanding as in Theorem 10.8.3,

$$\|\mathbf{w}\|^2 = 2\|\mathbf{x}\|\big(\|\mathbf{x}\| + x_1\big), \qquad \|\mathbf{w}'\|^2 = 2\|\mathbf{x}\|\big(\|\mathbf{x}\| - x_1\big),$$

and $(\|\mathbf{x}\| + x_1)(\|\mathbf{x}\| - x_1) = \|\widetilde{\mathbf{x}}\|^2$. Both vectors are built by the same two operations: compute $\|\mathbf{x}\|$, then add it to or subtract it from x_1. The computed norm carries an error of absolute size about $u\|\mathbf{x}\|$, and every other entry is copied from $\mathbf{x}$ exactly. So in both cases the computed vector is $\mathbf{w} + \Delta\mathbf{w}$ with $\|\Delta\mathbf{w}\| \approx u\|\mathbf{x}\|$ — *the same absolute error*. What differs is what that error is measured against, because $\mathbf{H}_{\mathbf{w}}$ depends on $\mathbf{w}$ only through the line it spans. Writing $\mathbf{p} = \mathbf{w}/\|\mathbf{w}\|$ and $\mathbf{q} = (\mathbf{w} + \Delta\mathbf{w})/\|\mathbf{w} + \Delta\mathbf{w}\|$, Definition 10.8.1 gives $\mathbf{H}_{\mathbf{w}} - \mathbf{H}_{\mathbf{w}+\Delta\mathbf{w}} = -2(\mathbf{p}\mathbf{p}^* - \mathbf{q}\mathbf{q}^*)$, and

$$\|\mathbf{p}\mathbf{p}^* - \mathbf{q}\mathbf{q}^*\| \le \|\mathbf{p}(\mathbf{p} - \mathbf{q})^*\| + \|(\mathbf{p} - \mathbf{q})\mathbf{q}^*\| = 2\|\mathbf{p} - \mathbf{q}\| \le \frac{8\|\Delta\mathbf{w}\|}{\|\mathbf{w}\|}.$$

For the last step, abbreviate $\mathbf{s} = \Delta\mathbf{w}$ and split

$$\mathbf{p} - \mathbf{q} = \mathbf{w}\Big(\frac{1}{\|\mathbf{w}\|} - \frac{1}{\|\mathbf{w} + \mathbf{s}\|}\Big) - \frac{\mathbf{s}}{\|\mathbf{w} + \mathbf{s}\|}.$$

The second piece has norm $\|\mathbf{s}\|/\|\mathbf{w} + \mathbf{s}\|$, and the first has norm $\big|\|\mathbf{w} + \mathbf{s}\| - \|\mathbf{w}\|\big|/\|\mathbf{w} + \mathbf{s}\|$, which is at most the same quantity by the reverse triangle inequality (Lemma 15.1.1); and $\|\mathbf{w} + \mathbf{s}\| \ge \|\mathbf{w}\|/2$ as soon as $\|\mathbf{s}\| \le \|\mathbf{w}\|/2$, which is certainly the case here, $\|\mathbf{s}\|$ being of size $u\|\mathbf{x}\|$. So the computed reflection differs from the intended one by a small multiple of

$$u\,\frac{\|\mathbf{x}\|}{\|\mathbf{w}\|}, \qquad \text{where} \qquad \frac{\|\mathbf{x}\|}{\|\mathbf{w}\|} = \sqrt{\frac{\|\mathbf{x}\|}{2(\|\mathbf{x}\| + x_1)}} \;\le\; \frac{1}{\sqrt{2}}.$$

The safe sign therefore never amplifies: its reflection is accurate to a small multiple of u, no matter what $\mathbf{x}$ is. The other sign amplifies by the factor

$$\frac{\|\mathbf{w}\|}{\|\mathbf{w}'\|} = \sqrt{\frac{\|\mathbf{x}\| + x_1}{\|\mathbf{x}\| - x_1}} = \frac{\|\mathbf{x}\| + x_1}{\|\widetilde{\mathbf{x}}\|},$$

which is **unbounded**: it blows up precisely as $\mathbf{x}$ approaches a positive multiple of $\mathbf{e}_1$, where $\|\widetilde{\mathbf{x}}\| \to 0$ and $\mathbf{w}' \to \mathbf{0}$.

Example. (The same vector, the two signs)

Let $\varepsilon = 10^{-8}$ and $\mathbf{x} = (1, \varepsilon, \varepsilon) \in \mathbb{R}^3$. Predict the amplification factor for each sign, then apply each computed reflection to $\mathbf{x}$ in the model with $u = 2^{-53}$ and measure how flat the answer is.

Solution. Prediction. $\|\widetilde{\mathbf{x}}\| = \sqrt{2}\,\varepsilon = 1.41 \cdot 10^{-8}$ and $\|\mathbf{x}\| = \sqrt{1 + 2\varepsilon^2}$, so $\|\mathbf{x}\|/\|\mathbf{w}\| = 0.5$ for the safe sign, while

$$\frac{\|\mathbf{x}\|}{\|\mathbf{w}'\|} = \sqrt{\frac{\|\mathbf{x}\|}{2(\|\mathbf{x}\| - 1)}} = 7.07 \cdot 10^{7}, \qquad u\,\frac{\|\mathbf{x}\|}{\|\mathbf{w}'\|} = 7.9 \cdot 10^{-9}.$$

The arithmetic. The computed $\|\mathbf{x}\|$ is exactly 1: the true value exceeds 1 by $\varepsilon^2 = 10^{-16}$, which is below the unit roundoff, so the addition returns 1. Hence

$$\widehat{\mathbf{w}} = (2, \varepsilon, \varepsilon), \qquad \widehat{\mathbf{w}}' = (0, \varepsilon, \varepsilon).$$

The first is right to full relative accuracy in every entry. The second has lost its first entry altogether: it should be -10^{-16} and it is 0. Applying Eq. 23.3.3,

$$\mathbf{H}_{\widehat{\mathbf{w}}}\,\mathbf{x} = (-1, 0, 0), \qquad \mathbf{H}_{\widehat{\mathbf{w}}'}\,\mathbf{x} = (1,\ -10^{-8},\ -10^{-8}).$$

The safe sign flattens $\mathbf{x}$ exactly: the two entries that were supposed to be annihilated are true zeros. The other sign leaves behind entries of size 10^{-8} beside a vector of norm 1 — a failure of $1.4 \cdot 10^{-8}$ where 10^{-16} was available, and within a factor of 2 of the estimate $u\|\mathbf{x}\|/\|\mathbf{w}'\| = 7.9 \cdot 10^{-9}$. Eight digits, thrown away by a sign.

For $\varepsilon = 10^{-6}$ and $\varepsilon = 10^{-4}$ the same computation leaves residues of $1.3 \cdot 10^{-10}$ and $1.5 \cdot 10^{-13}$, against estimates $7.9 \cdot 10^{-11}$ and $7.9 \cdot 10^{-13}$. The estimates fall by exactly 100 each time, as $1/\|\widetilde{\mathbf{x}}\|$ does; the residues fall by 112 and then by 825, because a residue depends on the actual rounding error committed in $\|\mathbf{x}\|$, which varies with the binary expansion of $\|\mathbf{x}\|$ and not only with its size. Over four orders of magnitude the estimate stays within a factor of 6 of the measurement, which is all an order-of-magnitude estimate promises.

Non-example by minimal change. Change one character of Example (The same vector, the two signs): take $\mathbf{x} = (-1, \varepsilon, \varepsilon)$ with $\varepsilon = 10^{-8}$. The arithmetic is unaltered — the computed $\|\mathbf{x}\|$ is again exactly 1 — and the rule of Theorem 10.8.3 still works: the phase of x_1 is now $\alpha = -1$, so $\mathbf{w} = \mathbf{x} + \alpha\|\mathbf{x}\|\mathbf{e}_1 = (-2, \varepsilon, \varepsilon)$, again with $\|\mathbf{x}\|/\|\mathbf{w}\| = 0.5$ and again flattening $\mathbf{x}$ to $(1, 0, 0)$ exactly. What fails is the rule with the phase dropped, $\mathbf{w} = \mathbf{x} + \|\mathbf{x}\|\mathbf{e}_1$: it returns $(0, \varepsilon, \varepsilon)$, and that reflection leaves $\mathbf{x}$ with the same residue $1.4 \cdot 10^{-8}$ as before. So the clause carrying the weight is not the plus sign but the **phase** α: what the rule requires is that $\alpha\|\mathbf{x}\|$ be added to x_1 so that the first entry grows in modulus, never so that it cancels. Reading the plus sign literally is correct mathematics for every $\mathbf{x}$ and correct arithmetic only for $x_1 > 0$.

Warning. **The bad sign is not merely inaccurate; on one input it does not exist.** If $\mathbf{x} = c\,\mathbf{e}_1$ with $c > 0$, then $\mathbf{w}' = \mathbf{0}$ and Definition 10.8.1 does not apply at all. That is not an accident of the arithmetic but the limit of the cancellation: the quantity whose leading digits are being destroyed is $\|\mathbf{x}\| - x_1$, and on that input it is zero. An algorithm that is undefined at a point is inaccurate near it, and the sign rule of Theorem 10.8.3 is exactly the rule that keeps the point out of reach.

23.3.6 Exercises

23.3.6.1 A. Check your understanding

Exercise A1.

(a) Define θ for a least-squares problem $\mathbf{Az} \approx \mathbf{b}$ with $\operatorname{rank}\mathbf{A} = n$, and say what $\theta = 0$ means about the system.

(b) State Theorem 23.3.1, and say which of its two terms survives when the residual is zero.

(c) Explain in one sentence why $\kappa_2(\mathbf{A})^2$ appears in the normal-equation route even for a consistent system, and why it need not appear in the reflection route.

(d) True or false: "a matrix with $\kappa_2(\mathbf{A}) = 10^3$ should never be handled by the normal equations". Justify your answer.

(e) What quantity does Theorem 23.3.3 bound, and which quantity does it **not** depend on?

Solution.

(a) By Eq. 23.3.1, $\theta \in [0, \pi/2]$ is determined by $\sin\theta = \|\mathbf{r}\|/\|\mathbf{b}\|$ with $\mathbf{r} = \mathbf{b} - \mathbf{Ax}$ the residual, equivalently $\cos\theta = \|\mathbf{Ax}\|/\|\mathbf{b}\|$; it is the angle between $\mathbf{b}$ and $\operatorname{col}(\mathbf{A})$. Then $\theta = 0$ says $\mathbf{r} = \mathbf{0}$, that is, the system $\mathbf{Az} = \mathbf{b}$ is consistent.

(b) See Theorem 23.3.1: the relative sensitivity is at most $\kappa_2(\mathbf{A})(\varepsilon_{\mathbf{A}} + \varepsilon_{\mathbf{b}}/\cos\theta) + \kappa_2(\mathbf{A})^2\varepsilon_{\mathbf{A}}\tan\theta$. With $\mathbf{r} = \mathbf{0}$ we get $\tan\theta = 0$, and only the $\kappa_2(\mathbf{A})$ term survives, with $\cos\theta = 1$.

(c) The normal-equation route solves a *different* linear system, the one with matrix $\mathbf{A}^*\mathbf{A}$, whose condition number is $\kappa_2(\mathbf{A})^2$ by Theorem 15.8.4, and the rounding committed in forming that matrix is magnified by its condition number, not by $\mathbf{A}$'s; the reflection route never forms the product, and $\kappa_2(\mathbf{R}) = \kappa_2(\mathbf{A})$.

(d) False. By Theorem 23.3.2 (a) the loss is about $2\log_{10}\kappa_2(\mathbf{A}) = 6$ digits out of sixteen, which is usually ample; the route costs about half the arithmetic. The warning after Example (A matrix where one route survives and the other does not) states the rule quantitatively: what matters is whether $u\kappa_2(\mathbf{A})^2$ is small enough for the purpose.

(e) It bounds the **backward** error of applying one reflection by the formula Eq. 23.3.3: the computed output is the exact output for an input perturbed by at most $(10m+16)u$ relatively. It does not depend on any condition number, only on m and u.

23.3.6.2 B. Practice

Exercise B1: Reading the bound.

Let $\mathbf{A} \in M_{50\times 3}(\mathbb{R})$ have $\kappa_2(\mathbf{A}) = 10^5$, and suppose the data are accurate to $\varepsilon = 10^{-10}$ relatively. Using Eq. 23.3.2 with $u \approx 10^{-16}$ where needed:

(a) Bound the relative error of the exact least-squares solution caused by the data error, when the residual is zero.

(b) Do the same when $\tan\theta = 1$.

(c) In case (b), how many digits does the normal-equation route lose on top of the data error, and how many does a backward stable method lose?

Solution.

(a) With $\theta = 0$, Eq. 23.3.2 gives $2\kappa_2(\mathbf{A})\varepsilon = 2 \cdot 10^5 \cdot 10^{-10} = 2 \cdot 10^{-5}$: about five correct digits, and no algorithm can restore them.

(b) With $\tan\theta = 1$ we have $\cos\theta = 1/\sqrt{2}$, so the bracket is $\kappa_2(1 + \sqrt{2}) + \kappa_2^2 = 2.4 \cdot 10^5 + 10^{10} \approx 10^{10}$, and the bound is $10^{10} \cdot 10^{-10} = 1$. The data alone determine nothing: the $\kappa_2^2 \tan\theta$ term has swallowed the problem.

(c) The arithmetic contributes $u\kappa_2(\mathbf{A})^2 = 10^{-16} \cdot 10^{10} = 10^{-6}$ for the normal equations and $u\,(\kappa_2 + \kappa_2^2 \tan\theta) \approx 10^{-6}$ for a backward stable method as well, by Theorem 23.3.2. In this case the two lose the same six digits — because the κ_2^2 is the problem's, not the algorithm's. Both are far below the 10^0 already lost to the data, so the choice of method is irrelevant here; it is for $\tan\theta$ small that it decides everything.

Exercise B2: Where the product goes singular.

Let $\mathbf{A} = \left(\begin{smallmatrix} 1 & 1 \\ \varepsilon & 0 \\ 0 & \varepsilon \end{smallmatrix}\right)$ as in Example (A matrix where one route survives and the other does not), in the model with $u = 2^{-53}$.

(a) For which ε does $\mathrm{fl}(1 + \varepsilon^2) = 1$ hold, and what is $\mathrm{fl}(\mathbf{A}^\top\mathbf{A})$ then?

(b) Express the threshold in (a) in terms of $\kappa_2(\mathbf{A})$ and u.

(c) Explain why the reflection route is untroubled at that threshold.

Solution.

(a) By Definition 23.1.1, $\mathrm{fl}(1 + \delta) = 1$ exactly when δ is at most the largest quantity that rounds away beside 1, which is $u = 2^{-53} \approx 1.11 \cdot 10^{-16}$. So $\mathrm{fl}(1 + \varepsilon^2) = 1$ for $\varepsilon^2 \le u$, that is $\varepsilon \lesssim 1.05 \cdot 10^{-8}$. Then every entry of $\mathrm{fl}(\mathbf{A}^\top\mathbf{A})$ is 1 and the computed matrix is $\left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$, which is singular: the information distinguishing the two columns has been rounded away.

(b) From Example (A matrix where one route survives and the other does not), $\kappa_2(\mathbf{A}) = \sqrt{2 + \varepsilon^2}/\varepsilon \approx \sqrt{2}/\varepsilon$, so $\varepsilon^2 \le u$ says $\kappa_2(\mathbf{A})^2 \ge 2/u$, that is $u\kappa_2(\mathbf{A})^2 \ge 2$. The normal equations collapse exactly when the bound of Theorem 23.3.2 (a) exceeds 1, which is the same as saying that the route promises no correct digit.

(c) The reflection route never computes $1 + \varepsilon^2$. It works with $\mathbf{A}$ itself, whose entries record ε and not ε^2, and by Theorem 23.3.3 each reflection perturbs the data relatively by $O(u)$. A relative perturbation of 10^{-16} in $\varepsilon = 10^{-9}$ leaves ε intact; a relative perturbation of 10^{-16} in 1 destroys $\varepsilon^2 = 10^{-18}$. Squaring is what moves the small quantity below the rounding level.

Exercise B3: One reflection, by hand.

Let $\mathbf{x} = (3, 0, 4) \in \mathbb{R}^3$.

(a) Compute $\mathbf{w}$ and $\mathbf{w}'$ as in Theorem 10.8.3, and the two amplification factors

$\|\mathbf{x}\|/\|\mathbf{w}\|$ and $\|\mathbf{x}\|/\|\mathbf{w}'\|$.

(b) Verify the identity $\|\mathbf{w}\|^2\|\mathbf{w}'\|^2 = 4\|\mathbf{x}\|^2\|\widetilde{\mathbf{x}}\|^2$ on this example.

(c) Is the sign choice important for this $\mathbf{x}$? Justify your answer.

Solution.

(a) $\|\mathbf{x}\| = 5$ and $x_1 = 3 > 0$, so $\alpha = 1$, $\mathbf{w} = (8, 0, 4)$ and $\mathbf{w}' = (-2, 0, 4)$. Then $\|\mathbf{w}\|^2 = 80$ and $\|\mathbf{w}'\|^2 = 20$, so

$$\frac{\|\mathbf{x}\|}{\|\mathbf{w}\|} = \frac{5}{\sqrt{80}} = \frac{\sqrt{5}}{4} \approx 0.559, \qquad \frac{\|\mathbf{x}\|}{\|\mathbf{w}'\|} = \frac{5}{\sqrt{20}} = \frac{\sqrt{5}}{2} \approx 1.118.$$

Both are of order 1. (The general formulas agree: $\|\mathbf{w}\|^2 = 2 \cdot 5 \cdot (5+3) = 80$ and $\|\mathbf{w}'\|^2 = 2 \cdot 5 \cdot (5-3) = 20$.)

(b) $\widetilde{\mathbf{x}} = (0, 4)$ has $\|\widetilde{\mathbf{x}}\|^2 = 16$, and $4\|\mathbf{x}\|^2\|\widetilde{\mathbf{x}}\|^2 = 4 \cdot 25 \cdot 16 = 1600 = 80 \cdot 20$. The identity is $\|\mathbf{w}\|^2\|\mathbf{w}'\|^2 = 4\|\mathbf{x}\|^2(\|\mathbf{x}\| + x_1)(\|\mathbf{x}\| - x_1) = 4\|\mathbf{x}\|^2\|\widetilde{\mathbf{x}}\|^2$.

(c) No. The amplification factor of the bad sign is $(\|\mathbf{x}\| + x_1)/\|\widetilde{\mathbf{x}}\| = 8/4 = 2$, so the two choices differ by a factor of 2 in accuracy, which is nothing. The sign matters only when $\mathbf{x}$ is close to a multiple of $\mathbf{e}_1$, that is when $\|\widetilde{\mathbf{x}}\| \ll \|\mathbf{x}\|$; here $\|\widetilde{\mathbf{x}}\| = 4$ is comparable with $\|\mathbf{x}\| = 5$.

23.3.6.3 C. Going deeper

Exercise C1: The squared term is attained.

Let $\varepsilon, \delta > 0$ and take

$$\mathbf{A} = \begin{pmatrix} 1 & 0 \\ 0 & \varepsilon \\ 0 & 0 \end{pmatrix}, \qquad \mathbf{b} = \begin{pmatrix} 1 \\ 0 \\ \delta \end{pmatrix}, \qquad \mathbf{E} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix}, \qquad \mathbf{f} = \mathbf{0}.$$

(a) Compute $\kappa_2(\mathbf{A})$, the least-squares solution $\mathbf{x}$, the residual $\mathbf{r}$ and $\tan\theta$.

(b) Using $(*)$ in the proof of Theorem 23.3.1, compute $\mathbf{x}'(0)$ exactly.

(c) Hence show that the squared term of Theorem 23.3.1 is attained, in the sense that $\|\mathbf{x}'(0)\|/\|\mathbf{x}\|$ equals $\kappa_2(\mathbf{A})^2\varepsilon_{\mathbf{A}}\tan\theta$ exactly, and explain what this says about any algorithm for this problem.

Solution.

(a) $\mathbf{A}^\top\mathbf{A} = \operatorname{diag}(1, \varepsilon^2)$, so the singular values are 1 and ε and $\kappa_2(\mathbf{A}) = 1/\varepsilon$ by the rectangular clause of Definition 15.8.1. The normal equations $\operatorname{diag}(1, \varepsilon^2)\mathbf{x} = \mathbf{A}^\top\mathbf{b} = (1, 0)$ give $\mathbf{x} = (1, 0)$. Then $\mathbf{A}\mathbf{x} = (1, 0, 0)$, so $\mathbf{r} = \mathbf{b} - \mathbf{A}\mathbf{x} = (0, 0, \delta)$ and, by Eq. 23.3.1,

$$\tan\theta = \frac{\|\mathbf{r}\|}{\|\mathbf{A}\mathbf{x}\|} = \delta.$$

Also $\|\mathbf{E}\| = 1 = \|\mathbf{A}\|$, so $\varepsilon_{\mathbf{A}} = 1$, and $\varepsilon_{\mathbf{b}} = 0$.

(b) The three terms of $(*)$. First, $\mathbf{E}^\top\mathbf{r} = \mathbf{e}_2(\mathbf{e}_3^\top\mathbf{r}) = \delta\,\mathbf{e}_2$, and $(\mathbf{A}^\top\mathbf{A})^{-1} = \operatorname{diag}(1, \varepsilon^{-2})$, so the first term is $(\delta/\varepsilon^2)\mathbf{e}_2$. Second, $\mathbf{E}\mathbf{x} = \mathbf{e}_3(\mathbf{e}_2^\top\mathbf{x}) = \mathbf{0}$ because $x_2 = 0$, so the

second term vanishes. Third, $\mathbf{f} = \mathbf{0}$. Hence

$$\mathbf{x}'(0) = \Big(0, \frac{\delta}{\varepsilon^2}\Big).$$

(c) $\|\mathbf{x}\| = 1$ and $\|\mathbf{x}'(0)\| = \delta/\varepsilon^2$, while

$$\kappa_2(\mathbf{A})^2\,\varepsilon_{\mathbf{A}}\tan\theta = \frac{1}{\varepsilon^2}\cdot 1\cdot\delta = \frac{\delta}{\varepsilon^2}.$$

The two agree exactly: the squared term is **attained**. The bound as a whole is not, and the reason is that the other two terms are non-negative — here the first of them contributes a further $\kappa_2(\mathbf{A})\varepsilon_{\mathbf{A}} = 1/\varepsilon$, so the bound exceeds $\|\mathbf{x}'(0)\|/\|\mathbf{x}\|$ by exactly that much. It is the squared term that matters, and what it says is that the sensitivity is a property of the data $(\mathbf{A}, \mathbf{b})$ alone: a perturbation of $\mathbf{A}$ of relative size $\varepsilon_{\mathbf{A}}$ really does move the exact answer by $\kappa_2(\mathbf{A})^2\tan\theta\,\varepsilon_{\mathbf{A}}$ relatively, so **no** algorithm, however stable, can return an answer better than that from data known only to within $\varepsilon_{\mathbf{A}}$. Compare Theorem 23.3.2 (b): a backward stable method achieves this and no more.

Exercise C2: Why the residual has to appear.

Let $\mathbf{A} \in M_{m\times n}(F)$ have rank n, and let $\mathbf{x}^+ = \mathbf{A}^+\mathbf{b}$ be the least-squares solution, where $\mathbf{A}^+$ is the pseudoinverse of Definition 12.11.1.

(a) Prove that $\mathbf{A}^+ = (\mathbf{A}^*\mathbf{A})^{-1}\mathbf{A}^*$ when $\operatorname{rank}\mathbf{A} = n$, and deduce $\|\mathbf{A}^+\| = 1/\sigma_n(\mathbf{A})$.

(b) Deduce from $(*)$ in the proof of Theorem 23.3.1 that if $\mathbf{E} = \mathbf{0}$ — only $\mathbf{b}$ is perturbed — then no $\kappa_2(\mathbf{A})^2$ term can appear, whatever the residual.

(c) Explain, in one or two sentences, why perturbing $\mathbf{A}$ is different: which term of $(*)$ carries the residual, and why it cannot be present when $\mathbf{E} = \mathbf{0}$.

Solution.

(a) Write $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$ (Theorem 12.8.1). Since $\operatorname{rank}\mathbf{A} = n$, $\sigma_1, \dots, \sigma_n > 0$, so $\mathbf{\Sigma}^+$ of Definition 12.11.1 has σ_i^{-1} on its diagonal and $\mathbf{A}^+ = \mathbf{V}\mathbf{\Sigma}^+\mathbf{U}^*$. On the other hand $\mathbf{A}^*\mathbf{A} = \mathbf{V}(\mathbf{\Sigma}^*\mathbf{\Sigma})\mathbf{V}^* = \mathbf{V}\operatorname{diag}(\sigma_i^2)\mathbf{V}^*$, so

$$(\mathbf{A}^*\mathbf{A})^{-1}\mathbf{A}^* = \mathbf{V}\operatorname{diag}(\sigma_i^{-2})\mathbf{V}^*\,\mathbf{V}\mathbf{\Sigma}^*\mathbf{U}^* = \mathbf{V}\big(\operatorname{diag}(\sigma_i^{-2})\mathbf{\Sigma}^*\big)\mathbf{U}^* = \mathbf{V}\mathbf{\Sigma}^+\mathbf{U}^* = \mathbf{A}^+,$$

because $\operatorname{diag}(\sigma_i^{-2})\mathbf{\Sigma}^*$ is the $n\times m$ matrix with entries $\sigma_i^{-2}\sigma_i = \sigma_i^{-1}$ on the diagonal and zeros elsewhere. Unitary factors leave singular values alone — $(\mathbf{V}\mathbf{\Sigma}^+\mathbf{U}^*)^*(\mathbf{V}\mathbf{\Sigma}^+\mathbf{U}^*) = \mathbf{U}(\mathbf{\Sigma}^{+*}\mathbf{\Sigma}^+)\mathbf{U}^*$ is unitarily similar to $\mathbf{\Sigma}^{+*}\mathbf{\Sigma}^+$, so the two have the same eigenvalues and Definition 12.8.1 reads the same singular values off them — so $\|\mathbf{A}^+\| = \|\mathbf{\Sigma}^+\| = \max_i \sigma_i^{-1} = 1/\sigma_n$ by Theorem 15.3.3 (c).

(b) With $\mathbf{E} = \mathbf{0}$, $(*)$ reduces to $\mathbf{x}'(0) = \mathbf{A}^+\mathbf{f}$, so by (a)

$$\frac{\|\mathbf{x}'(0)\|}{\|\mathbf{x}\|} \le \frac{\|\mathbf{f}\|}{\sigma_n\|\mathbf{x}\|} = \kappa_2(\mathbf{A})\,\varepsilon_{\mathbf{b}}\,\frac{\|\mathbf{b}\|}{\sigma_1\|\mathbf{x}\|} \le \frac{\kappa_2(\mathbf{A})\,\varepsilon_{\mathbf{b}}}{\cos\theta},$$

a single factor of $\kappa_2(\mathbf{A})$ however large $\|\mathbf{r}\|$ is. (The residual enters only through $1/\cos\theta$, which is bounded as long as θ is bounded away from $\pi/2$.)

(c) The residual sits in the term $(\mathbf{A}^*\mathbf{A})^{-1}\mathbf{E}^*\mathbf{r}$, and that is the only term with $(\mathbf{A}^*\mathbf{A})^{-1}$ *not* paired with an $\mathbf{A}^*$ — which is exactly why it carries σ_n^{-2} rather than σ_n^{-1}. It is proportional to $\mathbf{E}$, so it vanishes when $\mathbf{E} = \mathbf{0}$. Perturbing $\mathbf{b}$ tilts the target inside a fixed column space; perturbing $\mathbf{A}$ tilts the column space itself, and the residual is the lever arm by which that tilt moves the answer.

Exercise C3: A reflection applied to a matrix.

Let $\mathbf{H} = \mathbf{H}_{\mathbf{w}}$ be a Householder reflection in $\mathbb{R}^m$ and let $\mathbf{A} \in M_{m\times n}(\mathbb{R})$.

(a) Using Theorem 23.3.3 (b) and $\|\mathbf{M}\| \le \|\mathbf{M}\|_F \le \sqrt{n}\,\|\mathbf{M}\|$ for $\mathbf{M} \in M_{m\times n}$, show that the computed $\widehat{\mathbf{B}}$ satisfies $\|\widehat{\mathbf{B}} - \mathbf{H}\mathbf{A}\| \le (10m+16)\sqrt{n}\,u\,\|\mathbf{A}\|$.

(b) Deduce that $\sigma_i(\widehat{\mathbf{B}})$ differs from $\sigma_i(\mathbf{A})$ by at most $(10m+16)\sqrt{n}\,u\,\|\mathbf{A}\|$ for every i. *Hint: Chapter 19 §10 or Chapter 16 §09 bounds the perturbation of singular values by the norm of the perturbation.*

(c) Explain why the corresponding statement is false for the classical Gram–Schmidt process, citing Example (Three columns and three answers).

Solution.

(a) By Theorem 23.3.3 (b), $\widehat{\mathbf{B}} - \mathbf{H}\mathbf{A} = \mathbf{H}\,\Delta\mathbf{A}$ with $\|\Delta\mathbf{A}\|_F \le (10m+16)u\|\mathbf{A}\|_F$. Since $\mathbf{H}$ is unitary (Proposition 10.8.2 (c)) it leaves the 2-norm unchanged, so

$$\|\widehat{\mathbf{B}} - \mathbf{H}\mathbf{A}\| = \|\Delta\mathbf{A}\| \le \|\Delta\mathbf{A}\|_F \le (10m+16)u\|\mathbf{A}\|_F \le (10m+16)\sqrt{n}\,u\,\|\mathbf{A}\|.$$

(b) $\mathbf{H}\mathbf{A}$ has the same singular values as $\mathbf{A}$: $(\mathbf{H}\mathbf{A})^*(\mathbf{H}\mathbf{A}) = \mathbf{A}^*\mathbf{H}^*\mathbf{H}\mathbf{A} = \mathbf{A}^*\mathbf{A}$, so Definition 12.8.1 reads the same list off the same matrix. Weyl's inequality for singular values (Theorem 16.9.4 with $j = 1$, or Corollary 16.9.5 directly) gives $|\sigma_i(\widehat{\mathbf{B}}) - \sigma_i(\mathbf{H}\mathbf{A})| \le \|\widehat{\mathbf{B}} - \mathbf{H}\mathbf{A}\|$ for every i, and the right-hand side is bounded in (a).

(c) The Gram–Schmidt recursion of Theorem 10.2.2 does not apply a unitary matrix to $\mathbf{A}$; it *builds* a matrix $\widehat{\mathbf{Q}}$ out of $\mathbf{A}$ and hopes it is unitary. Example (Three columns and three answers) measures the damage: for $\kappa_2(\mathbf{A}) = 3\cdot10^6$ the computed vectors have inner products of size $9\cdot10^{-5}$, so $\widehat{\mathbf{Q}}$ is unitary only to five digits, and $\|\widehat{\mathbf{Q}}^\top\widehat{\mathbf{Q}} - \mathbf{I}\|$ exceeds u by eleven orders of magnitude on that one example. (That it does so at the rate $u\kappa_2(\mathbf{A})^2$ in general is the classical estimate quoted above, which this book does not prove.) Any conclusion drawn from "unitary factors leave singular values alone" then inherits that error instead of none. The reflection route wins because the unitary matrix is never in question: it is exactly unitary by construction, and only its *input* is perturbed.

23.4 The Power Method

Chapter 18 computed a Perron vector three times and each time stopped at the same place. Section 4 bracketed $\rho(\mathbf{A})$ by the ratios of $\mathbf{A}\mathbf{x}$ to $\mathbf{x}$ and observed: "the iteration $\mathbf{x} \mapsto \mathbf{A}\mathbf{x}$ is the power method, and Chapter 23 studies how fast it converges." Section 8 said the same of PageRank — "Chapter 23 studies it for general matrices, where the rate is governed by the ratio

of the two largest eigenvalue moduli" — and Section 9's ledger listed "the power method, the algorithm that computes a Perron vector at the size of the web" among the debts. Chapter 16 §01 and Chapter 19 §06 each promised, in the same words, that "Chapter 23 builds an iteration on" the Rayleigh quotient.

This section pays all five. It is about one idea used three times: **multiply by a matrix repeatedly and the largest eigenvalue takes over.** Applied to $\mathbf{A}$ itself, the idea finds the eigenvalue of largest modulus. Applied to $(\mathbf{A}-\mu\mathbf{I})^{-1}$, it finds the eigenvalue nearest μ — any eigenvalue we choose to aim at. Applied to $(\mathbf{A}-\mu\mathbf{I})^{-1}$ with μ refreshed at every step from the Rayleigh quotient, it converges cubically, and that is the iteration Chapters 16 and 19 promised.

Throughout, $F=\mathbb{R}$ or $F=\mathbb{C}$, matrices are in $M_n(F)$ read inside $M_n(\mathbb{C})$, and $\|\cdot\|=\|\cdot\|_2$. Iteration indices are superscripts in parentheses, so that subscripts stay free for coordinates.

23.4.1 Multiplying by the matrix

Take $\mathbf{A}$ diagonalizable with eigenbasis $\mathbf{v}_1,\dots,\mathbf{v}_n$ and eigenvalues $\lambda_1,\dots,\lambda_n$, and expand a starting vector:

$$\mathbf{x}=c_1\mathbf{v}_1+\cdots+c_n\mathbf{v}_n \quad\Longrightarrow\quad \mathbf{A}^k\mathbf{x}=c_1\lambda_1^k\mathbf{v}_1+\cdots+c_n\lambda_n^k\mathbf{v}_n.$$

Divide by λ_1^k, and suppose $|\lambda_1|$ is strictly the largest. Every coefficient except the first is multiplied by $(\lambda_i/\lambda_1)^k$, a number of modulus less than 1 raised to the k-th power. So the sum collapses onto its first term. Nothing here needs to be discovered; it needs to be named, and its rate measured.

The power method is: multiply, rescale, repeat, and read off the dominant eigenvector.

Definition 23.4.1 — Power Iteration

Let $\mathbf{A}\in M_n(F)$ and let $\mathbf{x}^{(0)}\in F^n$ with $\|\mathbf{x}^{(0)}\|=1$. The **power iteration** generated by $\mathbf{A}$ and $\mathbf{x}^{(0)}$ is the sequence defined for $k\ge 0$ by

$$\mathbf{x}^{(k+1)}=\frac{\mathbf{A}\mathbf{x}^{(k)}}{\|\mathbf{A}\mathbf{x}^{(k)}\|},$$

which is defined **as long as** $\mathbf{A}\mathbf{x}^{(k)}\neq\mathbf{0}$, together with the **eigenvalue estimates**

$$\mu_k=\big(\mathbf{x}^{(k)}\big)^{*}\mathbf{A}\,\mathbf{x}^{(k)}.$$

Clause by clause. The vectors are **unit** vectors: the normalization has no mathematical content, since $\mathbf{x}^{(k)}$ spans the same line as $\mathbf{A}^k\mathbf{x}^{(0)}$, and its only purpose is to stop the entries from growing or shrinking like λ_1^k until the arithmetic can no longer hold them. The iteration is **partial**: if $\mathbf{A}\mathbf{x}^{(k)}=\mathbf{0}$ the sequence stops, and it stops exactly when $\mathbf{x}^{(k)}\in\operatorname{nul}(\mathbf{A})$ — which, as we shall see, a good starting vector avoids. The estimate μ_k is the natural number to attach to a unit vector $\mathbf{x}$ that is nearly an eigenvector: if $\mathbf{A}\mathbf{x}=\lambda\mathbf{x}$ exactly then $\mathbf{x}^{*}\mathbf{A}\mathbf{x}=\lambda$. **For Hermitian $\mathbf{A}$ it is the Rayleigh quotient $R_{\mathbf{A}}(\mathbf{x}^{(k)})$ of Definition 16.1.1**, whose denominator is 1 here; for a general $\mathbf{A}$ the book reserves that name for the Hermitian case, so we write the quadratic form out.

Examples.

- **The identity.** $\mathbf{A} = \mathbf{I}$: every unit vector is fixed, $\mathbf{x}^{(k)} = \mathbf{x}^{(0)}$ for all k, and $\mu_k = 1$. The degenerate case is worth a glance, because it shows that the method converges to *an* eigenvector, never to a distinguished one.
- **A diagonal matrix.** $\mathbf{A} = \operatorname{diag}(3, 1)$ and $\mathbf{x}^{(0)} = \frac{1}{\sqrt{2}}(1, 1)$: then $\mathbf{A}^k\mathbf{x}^{(0)} \propto (3^k, 1)$, and the normalized vector runs to $\mathbf{e}_1$ with second coordinate 3^{-k}. The rate 3^{-k} is $|\lambda_2/\lambda_1|^k$.
- **A stochastic matrix.** For the Google matrix $\mathbf{G}$ of Chapter 18 §08, $\lambda_1 = 1$ and every other eigenvalue has modulus at most α (Theorem 18.8.2), so the iteration $\mathbf{x}_{k+1} = \mathbf{G}\mathbf{x}_k$ of Proposition 18.8.3 is a power iteration with rate at most α. Chapter 18 proved the rate directly from stochasticity, with no hypothesis on $\mathbf{G}$ beyond that; the theorem below proves it from the eigenvalues, for any diagonalizable matrix.

Non-example by minimal change. Replace $\operatorname{diag}(3, 1)$ by $\operatorname{diag}(3, -3)$. The eigenvalues now have **equal modulus**, the collapse never happens, and from $\mathbf{x}^{(0)} = \frac{1}{\sqrt{2}}(1, 1)$ the iterates alternate between $\frac{1}{\sqrt{2}}(1, 1)$ and $\frac{1}{\sqrt{2}}(1, -1)$ forever. One clause of the hypothesis has been dropped — strictness in $|\lambda_1| > |\lambda_2|$ — and the conclusion is gone with it.

Here is the theorem, with the rate.

Theorem 23.4.1 — The Power Method

Let $\mathbf{A} \in M_n(F)$ be diagonalizable, with a basis $\mathbf{v}_1, \dots, \mathbf{v}_n$ of eigenvectors, $\mathbf{A}\mathbf{v}_i = \lambda_i\mathbf{v}_i$, ordered by **modulus** so that

$$|\lambda_1| > |\lambda_2| \geq \cdots \geq |\lambda_n|.$$

Let $\mathbf{x}^{(0)} = c_1\mathbf{v}_1 + \cdots + c_n\mathbf{v}_n$ be a unit vector with $c_1 \neq 0$, and put $\rho = |\lambda_2/\lambda_1| < 1$, $\mathbf{q}_1 = \mathbf{v}_1/\|\mathbf{v}_1\|$ and

$$C = \frac{1}{\|\mathbf{v}_1\|} \sum_{i \geq 2} \left|\frac{c_i}{c_1}\right| \|\mathbf{v}_i\|.$$

Then the power iteration of Definition 23.4.1 is defined for every k, and for every k with $C\rho^k \leq \frac{1}{2}$ there is a scalar ω_k of modulus 1 with

(a) $\|\omega_k\mathbf{x}^{(k)} - \mathbf{q}_1\| \leq 4C\rho^k$;
(b) $|\mu_k - \lambda_1| \leq 8\|\mathbf{A}\|\, C\rho^k$.

In particular $\mu_k \to \lambda_1$, and the iterates approach the eigenline $\operatorname{span}(\mathbf{v}_1)$ in the sense of (a), both at the rate ρ^k.

Idea. The whole content is the display at the head of this subsection: divide $\mathbf{A}^k\mathbf{x}^{(0)}$ by $c_1\lambda_1^k$ and what is left is $\mathbf{v}_1$ plus a tail of size ρ^k. Two pieces of bookkeeping then stand between that and the statement. First, normalizing: a bound on $\mathbf{y} - \mathbf{v}_1$ is not yet a bound on $\mathbf{y}/\|\mathbf{y}\| - \mathbf{v}_1/\|\mathbf{v}_1\|$, and the conversion costs a factor 2 and the hypothesis $C\rho^k \leq \frac{1}{2}$, which only says that we are past the point where the tail could swamp $\mathbf{v}_1$. Second, phases: over $\mathbb{C}$ the scalar $c_1\lambda_1^k$ has a modulus and an argument, and normalizing kills the modulus but not the argument. That argument is the ω_k. It cancels out of μ_k, because a quadratic form does not see it.

Proof. **The iterates are defined, and what they are.** Since $c_1\lambda_1^k \neq 0$, the vector $\mathbf{A}^k\mathbf{x}^{(0)} = \sum_i c_i\lambda_i^k\mathbf{v}_i$ has a non-zero coefficient on $\mathbf{v}_1$, so $\mathbf{A}^k\mathbf{x}^{(0)} \neq \mathbf{0}$ for every k, the eigenvectors being a basis. An induction on k then gives $\mathbf{x}^{(k)} = \mathbf{A}^k\mathbf{x}^{(0)}/\|\mathbf{A}^k\mathbf{x}^{(0)}\|$: true at $k = 0$, and if it holds at k then $\mathbf{A}\mathbf{x}^{(k)}$ is a positive multiple of $\mathbf{A}^{k+1}\mathbf{x}^{(0)} \neq \mathbf{0}$, so normalizing it gives the same unit vector as normalizing $\mathbf{A}^{k+1}\mathbf{x}^{(0)}$.

The tail. Put

$$\mathbf{y}_k = \frac{\mathbf{A}^k\mathbf{x}^{(0)}}{c_1\lambda_1^k} = \mathbf{v}_1 + \mathbf{e}_k, \qquad \mathbf{e}_k = \sum_{i\geq 2}\frac{c_i}{c_1}\Big(\frac{\lambda_i}{\lambda_1}\Big)^k\mathbf{v}_i.$$

Since $|\lambda_i/\lambda_1| \leq \rho$ for $i \geq 2$, the triangle inequality (Corollary 10.1.6) gives

$$\|\mathbf{e}_k\| \leq \rho^k\sum_{i\geq 2}\Big|\frac{c_i}{c_1}\Big|\|\mathbf{v}_i\| = C\rho^k\|\mathbf{v}_1\|.$$

Normalizing. Let $\omega_k = \overline{\sigma_k}$, where $\sigma_k = c_1\lambda_1^k/|c_1\lambda_1^k|$ has modulus 1. Then $\mathbf{A}^k\mathbf{x}^{(0)} = |c_1\lambda_1^k|\,\sigma_k\mathbf{y}_k$, so $\mathbf{x}^{(k)} = \sigma_k\mathbf{y}_k/\|\mathbf{y}_k\|$ and $\omega_k\mathbf{x}^{(k)} = \mathbf{y}_k/\|\mathbf{y}_k\|$. For any non-zero $\mathbf{a}, \mathbf{b}$,

$$\frac{\mathbf{a}}{\|\mathbf{a}\|} - \frac{\mathbf{b}}{\|\mathbf{b}\|} = \frac{\mathbf{a}-\mathbf{b}}{\|\mathbf{a}\|} + \mathbf{b}\Big(\frac{1}{\|\mathbf{a}\|} - \frac{1}{\|\mathbf{b}\|}\Big),$$
$$\Big|\frac{1}{\|\mathbf{a}\|} - \frac{1}{\|\mathbf{b}\|}\Big|\|\mathbf{b}\| = \frac{\big|\|\mathbf{b}\| - \|\mathbf{a}\|\big|}{\|\mathbf{a}\|} \leq \frac{\|\mathbf{a}-\mathbf{b}\|}{\|\mathbf{a}\|},$$

the last step by the reverse triangle inequality (Lemma 15.1.1). Hence $\|\mathbf{a}/\|\mathbf{a}\| - \mathbf{b}/\|\mathbf{b}\|\| \leq 2\|\mathbf{a}-\mathbf{b}\|/\|\mathbf{a}\|$. Apply this with $\mathbf{a} = \mathbf{y}_k$ and $\mathbf{b} = \mathbf{v}_1$. If $C\rho^k \leq \frac{1}{2}$ then $\|\mathbf{e}_k\| \leq \frac{1}{2}\|\mathbf{v}_1\|$, so $\|\mathbf{y}_k\| \geq \|\mathbf{v}_1\| - \|\mathbf{e}_k\| \geq \frac{1}{2}\|\mathbf{v}_1\|$, and

$$\|\omega_k\mathbf{x}^{(k)} - \mathbf{q}_1\| \leq \frac{2\|\mathbf{e}_k\|}{\|\mathbf{y}_k\|} \leq \frac{4\|\mathbf{e}_k\|}{\|\mathbf{v}_1\|} \leq 4C\rho^k,$$

which is (a).

The estimates. Write $\mathbf{z} = \omega_k\mathbf{x}^{(k)}$, a unit vector, and note $\mu_k = (\mathbf{x}^{(k)})^*\mathbf{A}\mathbf{x}^{(k)} = \mathbf{z}^*\mathbf{A}\mathbf{z}$ because $\overline{\omega_k}\omega_k = 1$. Since $\mathbf{A}\mathbf{q}_1 = \lambda_1\mathbf{q}_1$ and $\|\mathbf{q}_1\| = 1$, we have $\mathbf{q}_1^*\mathbf{A}\mathbf{q}_1 = \lambda_1$, so

$$\mu_k - \lambda_1 = \mathbf{z}^*\mathbf{A}(\mathbf{z}-\mathbf{q}_1) + (\mathbf{z}-\mathbf{q}_1)^*\mathbf{A}\mathbf{q}_1.$$

By Cauchy–Schwarz (Theorem 10.1.5) and Theorem 15.3.2 (a), each term is at most $\|\mathbf{A}\|\|\mathbf{z}-\mathbf{q}_1\|$, so $|\mu_k - \lambda_1| \leq 2\|\mathbf{A}\|\|\mathbf{z}-\mathbf{q}_1\| \leq 8\|\mathbf{A}\|C\rho^k$ by (a). This proves the theorem. ∎

Aftermath. One matrix–vector product per step: $2n^2$ flops for a dense $\mathbf{A}$, and far fewer when $\mathbf{A}$ is sparse — for the hyperlink matrix of Chapter 18 §08, one operation per link. Nothing is factorized and nothing is stored but a vector, which is why the method survives at sizes where the matrix itself could never be written down. What it buys with that cheapness is a *linear* rate: to gain one decimal digit takes $1/\log_{10}(1/\rho)$ steps, and for $\rho = 0.99$ that is 230 of them.

Example. (Every iterate exactly)

Let $\mathbf{A} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ and $\mathbf{x}^{(0)} = \mathbf{e}_1$. Compute $\mathbf{A}^k\mathbf{e}_1$, the estimates μ_k, and the errors, in closed

form.

Solution. $\mathbf{A}$ has eigenvectors $(1,1)$ and $(1,-1)$ with eigenvalues 3 and 1, so $\rho = \frac{1}{3}$. Writing $\mathbf{e}_1 = \frac{1}{2}(1,1) + \frac{1}{2}(1,-1)$,

$$\mathbf{A}^k \mathbf{e}_1 = \tfrac{1}{2}3^k(1,1) + \tfrac{1}{2}(1,-1) = \Big(\frac{3^k+1}{2},\ \frac{3^k-1}{2}\Big).$$

So the iterates are proportional to $(1,0), (2,1), (5,4), (14,13), (41,40), (122,121), \ldots$, visibly running to the direction $(1,1)$. Put $t = 3^k$ and $\mathbf{x} = (a,b)$ with $a = (t+1)/2$, $b = (t-1)/2$. Then $a^2 + b^2 = (t^2+1)/2$ and $ab = (t^2-1)/4$, so

$$\mu_k = \frac{2a^2 + 2ab + 2b^2}{a^2 + b^2} = \frac{(t^2+1) + \frac{1}{2}(t^2-1)}{\frac{1}{2}(t^2+1)} = \frac{3t^2+1}{t^2+1} = 3 - \frac{2}{9^k+1}.$$

The values are $2,\ \frac{14}{5},\ \frac{122}{41},\ \frac{1094}{365},\ \frac{9842}{3281}$, with errors $1,\ \frac{1}{5},\ \frac{1}{41},\ \frac{1}{365},\ \frac{1}{3281}$ — falling by factors $5,\ 8.2,\ 8.9,\ 9.0$, so by about a ninth in the limit, not a third.

The eigenvector error tells the other half. The component of $\mathbf{x} = (a,b)$ orthogonal to $(1,1)$ is $\frac{1}{2}(a-b)(1,-1)$, of length $|a-b|/\sqrt{2} = 1/\sqrt{2}$, and $\|\mathbf{x}\| = \sqrt{(t^2+1)/2}$, so the sine of the angle between $\mathbf{x}^{(k)}$ and $(1,1)$ is $(9^k+1)^{-1/2}$, which does shrink like $3^{-k} = \rho^k$. Exactly:

$$3 - \mu_k = \frac{2}{9^k+1} = 2\sin^2\theta_k.$$

The eigenvector converges at rate ρ^k and the eigenvalue estimate at rate ρ^{2k}, and the second is the square of the first. That is not an accident of this matrix.

The corollary explains it, and pays Chapter 16 §01 in its own words.

Corollary 23.4.2 — Hermitian Matrices: the Rayleigh Quotient Converges Twice as Fast

Let $\mathbf{A} \in M_n(F)$ be Hermitian, with an orthonormal basis $\mathbf{q}_1, \ldots, \mathbf{q}_n$ of eigenvectors, $\mathbf{A}\mathbf{q}_i = \lambda_i \mathbf{q}_i$, ordered by modulus so that $|\lambda_1| > |\lambda_2| \geq \cdots \geq |\lambda_n|$. Let $\mathbf{x}^{(0)} = \sum_i c_i \mathbf{q}_i$ be a unit vector with $c_1 \neq 0$, and put $\rho = |\lambda_2/\lambda_1|$. Then for every k,

$$\big|R_{\mathbf{A}}(\mathbf{x}^{(k)}) - \lambda_1\big| \ \leq\ D\,\rho^{2k}, \qquad D = \frac{1}{|c_1|^2}\sum_{i\geq 2} |c_i|^2\,|\lambda_i - \lambda_1|.$$

Idea. The Rayleigh quotient is unchanged by scaling, so evaluate it at the unnormalized $\mathbf{A}^k\mathbf{x}^{(0)}$, where the coefficients are just $c_i\lambda_i^k$. Both the numerator and the denominator are then sums of *non-negative* multiples of λ_i^{2k} — the exponent is even, which is the whole point — so the denominator is bounded below by its first term alone, and the numerator, after λ_1 is subtracted, loses its first term entirely. What is left is λ_i^{2k} against λ_1^{2k}: one factor of ρ^2 per step.

Proof. Write $\mathbf{y} = \mathbf{A}^k\mathbf{x}^{(0)} = \sum_i c_i\lambda_i^k\mathbf{q}_i$. Since $c_1\lambda_1^k \neq 0$, $\mathbf{y} \neq \mathbf{0}$, and $\mathbf{x}^{(k)}$ is a scalar multiple of $\mathbf{y}$ as in the proof of Theorem 23.4.1, so $R_{\mathbf{A}}(\mathbf{x}^{(k)}) = R_{\mathbf{A}}(\mathbf{y})$ by the scale-invariance of the Rayleigh quotient (Definition 16.1.1). The basis is orthonormal and

$\mathbf{A}\mathbf{y} = \sum_i c_i \lambda_i^{k+1} \mathbf{q}_i$, so by Theorem 10.2.1 (b) and (c),

$$R_{\mathbf{A}}(\mathbf{y}) = \frac{\langle \mathbf{A}\mathbf{y}, \mathbf{y} \rangle}{\langle \mathbf{y}, \mathbf{y} \rangle} = \frac{\sum_i |c_i|^2 \lambda_i^{2k+1}}{\sum_i |c_i|^2 \lambda_i^{2k}},$$

all the λ_i being real (Proposition 10.6.7). Subtract λ_1, which is the same as subtracting λ_1 times the denominator from the numerator; the term $i = 1$ cancels, leaving

$$R_{\mathbf{A}}(\mathbf{y}) - \lambda_1 = \frac{\sum_{i \geq 2} |c_i|^2 \lambda_i^{2k} (\lambda_i - \lambda_1)}{\sum_i |c_i|^2 \lambda_i^{2k}}.$$

Every λ_i^{2k} is non-negative, so the denominator is at least its first term $|c_1|^2 \lambda_1^{2k} = |c_1|^2 |\lambda_1|^{2k}$, and the numerator is at most $|\lambda_2|^{2k} \sum_{i \geq 2} |c_i|^2 |\lambda_i - \lambda_1|$ in modulus, since $|\lambda_i| \leq |\lambda_2|$ for $i \geq 2$. Dividing gives the stated bound with $\rho^{2k} = (|\lambda_2|/|\lambda_1|)^{2k}$. This proves the corollary.

■

This is the "second-order accuracy" of Chapter 16 §01, seen along an iteration: the eigenvector error is ρ^k and the eigenvalue error is its square. Theorem 19.6.2 says the same thing structurally and without any iteration — a residual of size ε yields an eigenvalue error of at most ε^2 divided by the gap — and the corollary above is that estimate made explicit for the particular unit vectors the power method produces.

Quick check. In Example (Every iterate exactly) the estimates μ_k increase towards 3 and never overshoot. Which earlier result says that they cannot?

Solution. Proposition 16.1.1: for a Hermitian $\mathbf{A}$, the values of $R_{\mathbf{A}}$ fill exactly the interval $[\lambda_n(\mathbf{A}), \lambda_1(\mathbf{A})]$ between the smallest and largest eigenvalues. Here $\mathbf{A} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ has eigenvalues 3 and 1, so every $\mu_k = R_{\mathbf{A}}(\mathbf{x}^{(k)})$ lies in $[1, 3]$ and no estimate can exceed 3. The power method on a Hermitian matrix with $\lambda_1 > 0$ dominant therefore produces a sequence of certified *lower* bounds for λ_1, which is what Chapter 18 §04's brackets were doing by hand.

Example. (The method that never converges)

Let $\mathbf{P} \in M_3(\mathbb{R})$ be the cyclic permutation matrix of Example (The Cyclic Permutation), with columns $\mathbf{e}_2, \mathbf{e}_3, \mathbf{e}_1$, so that $\mathbf{P}(x_1, x_2, x_3) = (x_3, x_1, x_2)$. Run the power iteration from $\mathbf{x}^{(0)} = \mathbf{e}_1$ and from $\mathbf{x}^{(0)} = \frac{1}{\sqrt{14}}(1, 2, 3)$.

Solution. By Example (The Cyclic Permutation) the eigenvalues of $\mathbf{P}$ are the three cube roots of unity, all of modulus 1: the hypothesis $|\lambda_1| > |\lambda_2|$ fails as badly as it can. Every $\mathbf{P}^k$ is a permutation matrix, so no normalization is needed, and $\mathbf{P}^3 = \mathbf{I}$. From $\mathbf{e}_1$ the iterates are

$$\mathbf{e}_1 \to \mathbf{e}_2 \to \mathbf{e}_3 \to \mathbf{e}_1 \to \dots$$

and from $\frac{1}{\sqrt{14}}(1, 2, 3)$ they are $\frac{1}{\sqrt{14}}$ times $(1, 2, 3), (3, 1, 2), (2, 3, 1), (1, 2, 3), \dots$. In both cases the sequence takes three distinct values over and over, so neither it nor the line it spans has a limit. The estimates behave worse than that: they are *constant*, $\mu_k = 0$ for every k in the first case and $\mu_k = \frac{11}{14}$ in the second, so they converge perfectly well — to a number that is not an eigenvalue of $\mathbf{P}$ at all. Yet $\mathbf{P}$ does have the eigenvalue 1, with

eigenvector $\mathbf{1}$, and the method never finds it.

The failure is exactly the one Chapter 18 §04 warned of for the swap $\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$, whose brackets "never improve". It is not a defect of the arithmetic and no amount of care repairs it: the hypothesis of Theorem 23.4.1 is false, and its conclusion is false too.

Warning. **Two hypotheses, two different kinds of failure.** If $|\lambda_1| = |\lambda_2|$, as in Example (The method that never converges), the method fails permanently and no starting vector helps. If instead $c_1 = 0$ — the starting vector happens to miss the dominant eigendirection — the method converges, but to the wrong eigenvector. The second failure is fragile and the first is not: a starting vector with $c_1 = 0$ lies in a proper subspace, and in the arithmetic of Definition 23.1.1 the first rounding error generally puts a small non-zero c_1 back, after which Theorem 23.4.1 takes over, only C being large. This is the one situation in the chapter where rounding *helps*, and it is not a reason to rely on it: a starting vector chosen without regard to $\mathbf{A}$ is a better plan than a lucky rounding.

23.4.2 Shifting and inverting

The power method finds the eigenvalue of largest modulus, and that is usually not the one anybody wants. The repair is a change of matrix. If μ is not an eigenvalue of $\mathbf{A}$, then $\mathbf{A} - \mu\mathbf{I}$ is invertible, and the eigenvalues of its inverse are the numbers $(\lambda_i - \mu)^{-1}$ — **large exactly for the λ_i close to μ.** Multiplying repeatedly by $(\mathbf{A} - \mu\mathbf{I})^{-1}$ therefore singles out the eigenvalue nearest to μ, and μ is ours to choose.

Definition 23.4.2 — Inverse Iteration

Let $\mathbf{A} \in M_n(F)$, let $\mu \in F$ be **not an eigenvalue of $\mathbf{A}$**, and let $\mathbf{x}^{(0)}$ be a unit vector. **Inverse iteration with shift** μ is the power iteration of Definition 23.4.1 generated by $(\mathbf{A} - \mu\mathbf{I})^{-1}$ and $\mathbf{x}^{(0)}$; that is,

$$(\mathbf{A} - \mu\mathbf{I})\,\mathbf{z}^{(k)} = \mathbf{x}^{(k)}, \qquad \mathbf{x}^{(k+1)} = \frac{\mathbf{z}^{(k)}}{\|\mathbf{z}^{(k)}\|}.$$

The eigenvalue estimates are taken from $\mathbf{A}$ itself: $\mu_k = (\mathbf{x}^{(k)})^{*}\mathbf{A}\mathbf{x}^{(k)}$.

The shifted matrix is **never inverted**. One factorization of $\mathbf{A} - \mu\mathbf{I}$ by elimination with pivoting is computed once, at a cost of $\frac{2}{3}n^3$ flops (Section 2), and each step then costs two triangular solves, $2n^2$ flops — the same price per step as the power method, after a one-off payment.

Theorem 23.4.3 — Inverse Iteration Converges to the Nearest Eigenvector

Let $\mathbf{A} \in M_n(F)$ be diagonalizable with eigenbasis $\mathbf{v}_1, \dots, \mathbf{v}_n$ and eigenvalues $\lambda_1, \dots, \lambda_n$, and let $\mu \in F$ be not an eigenvalue of $\mathbf{A}$. Suppose there is an index j with

$$|\lambda_j - \mu| < |\lambda_i - \mu| \qquad \text{for every } i \neq j,$$

so that λ_j is the unique eigenvalue nearest μ. Let $\mathbf{x}^{(0)}$ be a unit vector whose $\mathbf{v}_j$-coefficient is non-zero. Then inverse iteration with shift μ is defined for every k, the iterates approach the eigenline $\operatorname{span}(\mathbf{v}_j)$ in the sense of Theorem 23.4.1 (a), and $\mu_k \to \lambda_j$, both at the rate ρ_μ^k, where

$$\rho_\mu = \frac{|\lambda_j - \mu|}{\min_{i \neq j} |\lambda_i - \mu|} < 1.$$

Idea. There is nothing to prove that Theorem 23.4.1 has not proved. The only work is to check that $(\mathbf{A} - \mu\mathbf{I})^{-1}$ satisfies its hypotheses — same eigenvectors, reciprocal shifted eigenvalues, a strict winner in modulus — and to read off what the ratio ρ of that theorem becomes after the reciprocals are taken: dividing by the largest reciprocal is multiplying by the smallest difference, so the ratio turns upside down.

Proof. Let $\mathbf{V} = (\mathbf{v}_1 \mid \cdots \mid \mathbf{v}_n)$, invertible because its columns are a basis, and $\mathbf{\Lambda} = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$, so that $\mathbf{A} = \mathbf{V}\mathbf{\Lambda}\mathbf{V}^{-1}$ (Theorem 8.4.1). Then

$$\mathbf{A} - \mu\mathbf{I} = \mathbf{V}(\mathbf{\Lambda} - \mu\mathbf{I})\mathbf{V}^{-1},$$

and $\mathbf{\Lambda} - \mu\mathbf{I}$ is invertible because no λ_i equals μ. Hence $\mathbf{B} := (\mathbf{A} - \mu\mathbf{I})^{-1} = \mathbf{V}(\mathbf{\Lambda} - \mu\mathbf{I})^{-1}\mathbf{V}^{-1}$ is diagonalizable, with the **same** eigenvectors $\mathbf{v}_i$ and eigenvalues $\beta_i = (\lambda_i - \mu)^{-1}$.

Their moduli are $|\beta_i| = 1/|\lambda_i - \mu|$, so the hypothesis on j says exactly that $|\beta_j| > |\beta_i|$ for every $i \neq j$: the eigenvalue β_j is strictly dominant. Relabeling so that j comes first, the second largest modulus is $\max_{i \neq j} |\beta_i| = 1/\min_{i \neq j} |\lambda_i - \mu|$, so the ratio of Theorem 23.4.1 is

$$\frac{\max_{i \neq j} |\beta_i|}{|\beta_j|} = \frac{|\lambda_j - \mu|}{\min_{i \neq j} |\lambda_i - \mu|} = \rho_\mu.$$

Since the $\mathbf{v}_j$-coefficient of $\mathbf{x}^{(0)}$ is non-zero, Theorem 23.4.1 applies to $\mathbf{B}$ and $\mathbf{x}^{(0)}$ and gives unimodular ω_k with $\|\omega_k \mathbf{x}^{(k)} - \mathbf{q}_j\| \leq 4C\rho_\mu^k$, where $\mathbf{q}_j = \mathbf{v}_j / \|\mathbf{v}_j\|$ and C is that theorem's constant for $\mathbf{B}$ and $\mathbf{x}^{(0)}$. That is the convergence of the line.

For the estimates, repeat the last paragraph of the proof of Theorem 23.4.1 with $\mathbf{A}$ in place of $\mathbf{B}$: with $\mathbf{z} = \omega_k \mathbf{x}^{(k)}$ we have $\mu_k = \mathbf{z}^* \mathbf{A} \mathbf{z}$ and $\mathbf{q}_j^* \mathbf{A} \mathbf{q}_j = \lambda_j$, so $|\mu_k - \lambda_j| \leq 2\|\mathbf{A}\| \|\mathbf{z} - \mathbf{q}_j\| \leq 8\|\mathbf{A}\| C \rho_\mu^k$. This proves the theorem.

■

Example. (Aiming at the smaller eigenvalue)

Let $\mathbf{A} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ again, and take the shift $\mu = \frac{3}{4}$, which is nearer to the eigenvalue 1 than to 3. Run inverse iteration from $\mathbf{x}^{(0)} = \mathbf{e}_1$, and compare with Example (Every iterate exactly).

Solution. $\mathbf{A} - \frac{3}{4}\mathbf{I} = \left(\begin{smallmatrix} 5/4 & 1 \\ 1 & 5/4 \end{smallmatrix}\right)$ has determinant $\frac{25}{16} - 1 = \frac{9}{16}$, so

$$\left(\mathbf{A} - \tfrac{3}{4}\mathbf{I}\right)^{-1} = \tfrac{16}{9} \begin{pmatrix} 5/4 & -1 \\ -1 & 5/4 \end{pmatrix} = \tfrac{1}{9} \begin{pmatrix} 20 & -16 \\ -16 & 20 \end{pmatrix}.$$

Ignoring positive scalars, each step is $(a,b)\mapsto(5a-4b,\ -4a+5b)$, so the iterates are

$$(1,0)\to(5,-4)\to(41,-40)\to(365,-364)\to(3281,-3280)\to\dots,$$

running to the direction $(1,-1)$ — the eigenvector of the eigenvalue 1. In closed form: the eigenvalues of $(\mathbf{A}-\frac{3}{4}\mathbf{I})^{-1}$ are $(3-\frac{3}{4})^{-1}=\frac{4}{9}$ and $(1-\frac{3}{4})^{-1}=4$, so expanding $\mathbf{e}_1=\frac{1}{2}(1,1)+\frac{1}{2}(1,-1)$ gives

$$\big(\mathbf{A}-\tfrac{3}{4}\mathbf{I}\big)^{-k}\mathbf{e}_1=\tfrac{1}{2}\big(\tfrac{4}{9}\big)^k(1,1)+\tfrac{1}{2}4^k(1,-1)\ \propto\ \big(9^k+1,\ -(9^k-1)\big),$$

the last step on multiplying by $2(9/4)^k$. Halving, this is the list above. Writing $\mathbf{x}=(a,b)$ with $a+b=1$, we have $2ab=1-(a^2+b^2)$ and so

$$\mu_k=\frac{2a^2+2ab+2b^2}{a^2+b^2}=1+\frac{1}{a^2+b^2}=1+\frac{2}{81^k+1},$$

since $a^2+b^2=\frac{1}{2}(81^k+1)$. The errors are $1,\frac{1}{41},\frac{1}{3281},\frac{1}{265721},\frac{1}{21523361},\dots$, each about $\frac{1}{81}$ of the last, while the sine of the angle to $(1,-1)$ is $(81^k+1)^{-1/2}$, shrinking by $\frac{1}{9}$ per step. The theorem predicts exactly that:

$$\rho_\mu=\frac{|1-\frac{3}{4}|}{|3-\frac{3}{4}|}=\frac{1/4}{9/4}=\frac{1}{9},$$

with the estimates again going at the squared rate $\rho_\mu^{2k}=81^{-k}$, as in Example (Every iterate exactly) and for the same reason. Compare that example, where the same matrix and the same starting vector gave rate $\frac{1}{3}$ towards the *other* eigenvector: one well-chosen shift has both redirected the method and made it gain twice as many digits per step.

The objection, and the answer. If μ is close to λ_j, then $\mathbf{A}-\mu\mathbf{I}$ is close to singular and $\kappa_2(\mathbf{A}-\mu\mathbf{I})$ is enormous. For normal $\mathbf{A}=\mathbf{U}\mathbf{D}\mathbf{U}^*$ (Corollary 11.4.3) we have $\mathbf{A}-\mu\mathbf{I}=\mathbf{U}(\mathbf{D}-\mu\mathbf{I})\mathbf{U}^*$, whose singular values are the numbers $|\lambda_i-\mu|$, so by Proposition 15.8.2 (d)

$$\kappa_2(\mathbf{A}-\mu\mathbf{I})=\frac{\max_i|\lambda_i-\mu|}{|\lambda_j-\mu|},$$

which grows without bound as $\mu\to\lambda_j$. Section 3 spent its length on how much a large condition number costs. And the better the shift, the worse the conditioning: **the method is deliberately solving an ill-conditioned system, and it does so on purpose.**

It does no harm, and here is why. Suppose the linear solve is backward stable in the sense of Definition 23.1.3, so that the computed $\widehat{\mathbf{z}}$ is the exact solution of

$$(\mathbf{A}-\mu\mathbf{I}+\mathbf{\Delta})\widehat{\mathbf{z}}=\mathbf{x},\qquad \|\mathbf{\Delta}\|\le c\,u\,\|\mathbf{A}-\mu\mathbf{I}\|,$$

for a unit $\mathbf{x}$. The computed $\widehat{\mathbf{z}}$ may be wrong in every digit — the forward error is bounded only by $\kappa_2(\mathbf{A}-\mu\mathbf{I})cu$, which may exceed 1. But rearrange the same equation as a residual: $(\mathbf{A}-\mu\mathbf{I})\widehat{\mathbf{z}}-\mathbf{x}=-\mathbf{\Delta}\widehat{\mathbf{z}}$, so the **normalized** vector $\widehat{\mathbf{q}}=\widehat{\mathbf{z}}/\|\widehat{\mathbf{z}}\|$ satisfies

$$\|\mathbf{A}\widehat{\mathbf{q}}-\mu\widehat{\mathbf{q}}\|\ \le\ \frac{1}{\|\widehat{\mathbf{z}}\|}+c\,u\,\|\mathbf{A}-\mu\mathbf{I}\|.$$

The first term is small when $\|\widehat{\mathbf{z}}\|$ is large, and that takes an argument and a hypothesis. Near-singularity alone will not supply it: for $\mathbf{A}=\operatorname{diag}(1,2)$, $\mu=1+10^{-10}$ and $\mathbf{x}=\mathbf{e}_2$, the matrix $\mathbf{A}-\mu\mathbf{I}$ is as near singular as one pleases and yet $\mathbf{z}=(\mathbf{A}-\mu\mathbf{I})^{-1}\mathbf{x}$ has norm 1 to ten digits. What is needed is that $\mathbf{x}$ *see* the near-singular direction.

Take $\mathbf{A}$ normal with orthonormal eigenbasis $\mathbf{q}_1, \dots, \mathbf{q}_n$ (Corollary 11.4.3), so that $\mathbf{A}^*\mathbf{q}_j = \overline{\lambda_j}\mathbf{q}_j$ and hence $\mathbf{q}_j^*(\mathbf{A} - \mu\mathbf{I}) = (\lambda_j - \mu)\mathbf{q}_j^*$. Multiplying the perturbed equation by $\mathbf{q}_j^*$ gives $\mathbf{q}_j^*\mathbf{x} = (\lambda_j - \mu)\mathbf{q}_j^*\widehat{\mathbf{z}} + \mathbf{q}_j^*\boldsymbol{\Delta}\widehat{\mathbf{z}}$, so by Cauchy–Schwarz (Theorem 10.1.5) and Theorem 15.3.2 (a),

$$\|\widehat{\mathbf{z}}\| \;\geq\; \frac{|\mathbf{q}_j^*\mathbf{x}|}{|\lambda_j - \mu| + \|\boldsymbol{\Delta}\|}.$$

So a shift close to λ_j does force $\|\widehat{\mathbf{z}}\|$ to be large, **provided the component $\mathbf{q}_j^*\mathbf{x}$ is not small** — which is the hypothesis Theorem 23.4.3 already makes on the starting vector. Granting it, the first term of the residual bound is small, and the second is at the rounding level. **The residual of the normalized answer is small even though the answer itself is inaccurate**, and a small residual is all that an eigenvector approximation has to have.

For Hermitian $\mathbf{A}$ one can say precisely how much it buys. Let $\widehat{\mathbf{q}}$ be a unit vector, $\widehat{\mu} = R_{\mathbf{A}}(\widehat{\mathbf{q}})$ its Rayleigh quotient and $\varepsilon = \|\mathbf{A}\widehat{\mathbf{q}} - \widehat{\mu}\widehat{\mathbf{q}}\|$ its residual. Expand $\widehat{\mathbf{q}} = \sum_i d_i\mathbf{q}_i$ in an orthonormal eigenbasis (Corollary 11.4.3); by Theorem 10.2.1 (c),

$$\varepsilon^2 = \sum_i |d_i|^2(\lambda_i - \widehat{\mu})^2.$$

If λ_j is the only eigenvalue within distance g of $\widehat{\mu}$, every term with $i \neq j$ has $(\lambda_i - \widehat{\mu})^2 \geq g^2$, so $\sum_{i\neq j}|d_i|^2 \leq \varepsilon^2/g^2$ and the sine of the angle between $\widehat{\mathbf{q}}$ and $\mathbf{q}_j$ is at most ε/g. Together with Theorem 19.6.1, which puts an eigenvalue of $\mathbf{A}$ within ε of $\widehat{\mu}$, and Theorem 19.6.2, which improves that to ε^2/g, the small residual certifies both halves of the answer.

> *Warning.* **"Ill-conditioned" is a statement about the wrong question.** The system $(\mathbf{A} - \mu\mathbf{I})\mathbf{z} = \mathbf{x}$ is indeed almost unsolvable *if what is wanted is* $\mathbf{z}$. What is wanted is the direction of $\mathbf{z}$, and the direction is precisely the part the ill-conditioning leaves alone: the huge factor $1/(\lambda_j - \mu)$ multiplies the component along $\mathbf{v}_j$, which is the component being sought, and dividing by $\|\widehat{\mathbf{z}}\|$ removes it. The residual estimate above is the rigorous form of that sentence. The same reasoning does **not** license inverse iteration when the eigenvalue is not simple or two eigenvalues are nearly equal: then g is small, the bound ε/g says nothing, and the computed direction really is unreliable.

23.4.3 The shift that improves itself

Inverse iteration needs a shift, and a better shift converges faster. But the iteration is manufacturing better and better approximations to λ_j as it goes, in the estimates μ_k. Use them.

Definition 23.4.3 — Rayleigh Quotient Iteration

Let $\mathbf{A} \in M_n(F)$ be Hermitian and let $\mathbf{x}^{(0)}$ be a unit vector. **Rayleigh quotient iteration** is the sequence defined for $k \geq 0$ by

$$\mu_k = R_{\mathbf{A}}(\mathbf{x}^{(k)}) = (\mathbf{x}^{(k)})^*\mathbf{A}\mathbf{x}^{(k)}, \qquad (\mathbf{A} - \mu_k\mathbf{I})\mathbf{z}^{(k)} = \mathbf{x}^{(k)}, \qquad \mathbf{x}^{(k+1)} = \frac{\mathbf{z}^{(k)}}{\|\mathbf{z}^{(k)}\|},$$

the step being **undefined, and the iteration stopped, when μ_k is an eigenvalue of $\mathbf{A}$** — in which case μ_k is the answer, exactly.

It is inverse iteration with the shift refreshed at every step, and it is what Chapter 16 §01 and Chapter 19 §06 both promised. The price is a new factorization of $\mathbf{A}-\mu_k\mathbf{I}$ at every step, $\frac{2}{3}n^3$ flops instead of $2n^2$. What is bought is the following rate.

Theorem 23.4.4 — Rayleigh Quotient Iteration Converges Cubically

Let $\mathbf{A}\in M_n(F)$ be Hermitian with an orthonormal basis $\mathbf{q}_1,\dots,\mathbf{q}_n$ of eigenvectors, $\mathbf{A}\mathbf{q}_i=\lambda_i\mathbf{q}_i$, and fix an index j whose eigenvalue is **simple**. Put

$$g=\min_{i\neq j}|\lambda_i-\lambda_j|>0,\qquad D=\max_{i\neq j}|\lambda_i-\lambda_j|,$$

and for a unit vector $\mathbf{x}$ write $s(\mathbf{x})=\|\mathbf{x}-\mathbf{q}_j\mathbf{q}_j^*\mathbf{x}\|$, the length of the part of $\mathbf{x}$ orthogonal to $\mathbf{q}_j$.

Let $\mathbf{x}=\mathbf{x}^{(k)}$ be a unit iterate with $s=s(\mathbf{x})$ satisfying $s\le\frac{1}{2}$ and $Ds^2\le\frac{g}{2}$. Then $|\mu_k-\lambda_j|\le Ds^2$, and either $\mu_k=\lambda_j$ — the iteration has found the eigenvalue exactly — or the next iterate is defined and

$$s\big(\mathbf{x}^{(k+1)}\big)\;\le\;\frac{4D}{g}\,s^3.$$

Consequently, if $s_0=s(\mathbf{x}^{(0)})$ satisfies $s_0\le\frac{1}{2}$ and $s_0^2\le g/(8D)$, then $a_k:=\sqrt{4D/g}\;s(\mathbf{x}^{(k)})$ satisfies $a_k\le a_0^{3^k}$ with $a_0\le 1/\sqrt{2}$, so $s(\mathbf{x}^{(k)})\to 0$ and $\mu_k\to\lambda_j$.

Idea. Two facts, multiplied together. The Rayleigh quotient is accurate to *second* order in the eigenvector error, so a shift built from an iterate at distance s is wrong by only Ds^2 — that is Corollary 23.4.2's squaring again, in its non-iterative form. And one step of inverse iteration with a shift wrong by δ multiplies the error by about δ/g. Put $\delta=Ds^2$ and the step multiplies s by Ds^2/g: a factor s^2 per step, which is one cube. Everything else is the arithmetic of keeping the shift far enough from the other eigenvalues for g to survive, and that is what the two smallness hypotheses are for.

Proof. Expand $\mathbf{x}=\sum_i c_i\mathbf{q}_i$ with $\sum_i|c_i|^2=1$ (Theorem 10.2.1 (c)). Then $\mathbf{q}_j\mathbf{q}_j^*\mathbf{x}=c_j\mathbf{q}_j$, so

$$s^2=\sum_{i\neq j}|c_i|^2,\qquad |c_j|^2=1-s^2.$$

Step 1: the shift is accurate to second order. By Theorem 10.2.1 (b), $\mu_k=\mathbf{x}^*\mathbf{A}\mathbf{x}=\sum_i|c_i|^2\lambda_i$, and since the weights sum to 1,

$$\mu_k-\lambda_j=\sum_{i\neq j}|c_i|^2(\lambda_i-\lambda_j),\qquad |\mu_k-\lambda_j|\le D\sum_{i\neq j}|c_i|^2=Ds^2.$$

Step 2: the shift stays away from the other eigenvalues. By hypothesis $Ds^2\le g/2$, so $|\mu_k-\lambda_j|\le g/2$ and, for $i\neq j$,

$$|\lambda_i-\mu_k|\ge|\lambda_i-\lambda_j|-|\lambda_j-\mu_k|\ge g-\tfrac{g}{2}=\tfrac{g}{2}>0.$$

In particular the only eigenvalue μ_k can equal is λ_j. If it does, the iteration stops with the exact answer. Otherwise $\mathbf{A}-\mu_k\mathbf{I}$ is invertible and the step is defined.

Step 3: one step. Since $\mathbf{A}\mathbf{q}_i = \lambda_i \mathbf{q}_i$,

$$\mathbf{z}^{(k)} = (\mathbf{A} - \mu_k \mathbf{I})^{-1}\mathbf{x} = \sum_i \frac{c_i}{\lambda_i - \mu_k}\,\mathbf{q}_i.$$

The quantity $s(\cdot)$ is unchanged by scaling, so $s(\mathbf{x}^{(k+1)}) = s(\mathbf{z}^{(k)}/\|\mathbf{z}^{(k)}\|)$ is the ratio of the length of the part of $\mathbf{z}^{(k)}$ orthogonal to $\mathbf{q}_j$ to the length of $\mathbf{z}^{(k)}$:

$$s\big(\mathbf{x}^{(k+1)}\big)^2 = \frac{\displaystyle\sum_{i\neq j} \frac{|c_i|^2}{|\lambda_i - \mu_k|^2}}{\displaystyle\sum_i \frac{|c_i|^2}{|\lambda_i - \mu_k|^2}}.$$

Bound the numerator above using Step 2, and the denominator below by its $i = j$ term alone:

$$s\big(\mathbf{x}^{(k+1)}\big)^2 \;\le\; \frac{(2/g)^2\, s^2}{|c_j|^2/|\lambda_j - \mu_k|^2} \;=\; \frac{4s^2|\lambda_j - \mu_k|^2}{g^2\,(1 - s^2)} \;\le\; \frac{4s^2 D^2 s^4}{g^2(1 - s^2)},$$

using Step 1 at the end. Taking square roots and using $s \le \tfrac{1}{2}$, so that $\sqrt{1 - s^2} \ge \tfrac{\sqrt{3}}{2} \ge \tfrac{1}{2}$,

$$s\big(\mathbf{x}^{(k+1)}\big) \;\le\; \frac{2D\, s^3}{g\sqrt{1 - s^2}} \;\le\; \frac{4D}{g}\, s^3.$$

Step 4: the iteration. Put $C = 4D/g$ and $a_k = \sqrt{C}\, s(\mathbf{x}^{(k)})$. The hypotheses $s_0 \le \tfrac{1}{2}$ and $s_0^2 \le g/(8D)$ give $a_0^2 = C s_0^2 \le \tfrac{1}{2}$, so $a_0 \le 1/\sqrt{2} < 1$, and also $D s_0^2 \le g/2$. Whenever the hypotheses hold at step k, Step 3 gives $a_{k+1} \le \sqrt{C}\, C s_k^3 = a_k^3$, so $a_{k+1} \le a_k^3 \le a_k \le a_0$; hence $s_{k+1} \le s_k \le s_0 \le \tfrac{1}{2}$ and $D s_{k+1}^2 \le D s_0^2 \le g/2$, and the hypotheses hold again. By induction $a_k \le a_0^{3^k}$ for every k. Since $a_0 < 1$, $a_k \to 0$ and so $s(\mathbf{x}^{(k)}) \to 0$; by Step 1, $|\mu_k - \lambda_j| \le D s_k^2 \to 0$. This proves the theorem.

■

Cubic convergence is a different animal from the linear convergence of Theorem 23.4.1. Each step roughly **triples the number of correct digits**, so an iterate with two correct digits has six after one step and eighteen after two — which is more than the arithmetic holds. In practice the iteration is over in three or four steps from any reasonable start, and the cost is dominated by those three or four factorizations.

Example. (Three steps, exactly)

Run Rayleigh quotient iteration on $\mathbf{A} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ from $\mathbf{x}^{(0)} \propto (2, 1)$, in exact arithmetic.

Solution. Write each iterate as an integer vector, scaling being irrelevant. Take $\mathbf{q}_j = \frac{1}{\sqrt{2}}(1, 1)$, so $\lambda_j = 3$, and here $g = D = 2$, giving $4D/g = 4$.

Step 0. $\mathbf{x} \propto (2, 1)$. Then $\mu_0 = (2\cdot 2^2 + 2\cdot 2\cdot 1 + 2\cdot 1^2)/5 = \frac{14}{5}$, and $\mathbf{A} - \frac{14}{5}\mathbf{I} = \left(\begin{smallmatrix} -4/5 & 1 \\ 1 & -4/5 \end{smallmatrix}\right)$ has determinant $-\frac{9}{25}$. Solving gives $\mathbf{z} \propto (13, 14)$.

Step 1. $\mathbf{x} \propto (13, 14)$, $\mu_1 = \frac{1094}{365}$, and $3 - \mu_1 = \frac{1}{365}$. Solving again gives $\mathbf{z} \propto (9842, 9841)$.

Step 2. $\mu_2 = \frac{581130734}{193710245}$, with $3 - \mu_2 = \frac{1}{193710245}$.

Step 3. $\mathbf{x} \propto (3812798742493,\ 3812798742494)$ and $3 - \mu_3 = \frac{1}{290748685015200298451950 85}$.

The eigenvalue errors are

$$2 \cdot 10^{-1}, \quad 2.7 \cdot 10^{-3}, \quad 5.2 \cdot 10^{-9}, \quad 3.4 \cdot 10^{-26},$$

and the eigenvector errors s_k are

$$3.16 \cdot 10^{-1}, \quad 3.70 \cdot 10^{-2}, \quad 5.08 \cdot 10^{-5}, \quad 1.31 \cdot 10^{-13}.$$

Check the theorem: $s_1/s_0^3 = 1.17$, $s_2/s_1^3 = 1.00$, $s_3/s_2^3 = 1.00$, all comfortably below the predicted constant $4D/g = 4$. Four steps have produced twenty-five correct digits from a starting vector accurate to none.

Remark. **The non-Hermitian rate is quadratic, and we do not prove it.** For a general diagonalizable $\mathbf{A}$, with μ_k taken to be $(\mathbf{x}^{(k)})^* \mathbf{A} \mathbf{x}^{(k)}$, the same iteration converges locally at a *quadratic* rate rather than a cubic one. The reason is visible in Step 1 above: it used that μ_k is a weighted average of the eigenvalues with weights $|c_i|^2$, so that the first-order term in s is absent — and that identity is exactly the Hermitian spectral theorem at work. Without it the shift is accurate only to first order, $|\mu_k - \lambda_j| = O(s)$, and the step multiplies s by $O(s)$. **The general statement is classical and is not proved here**, and nothing in this book depends on it.

23.4.4 Deflation, and what comes next

One eigenpair is rarely enough. For Hermitian $\mathbf{A}$, once a unit eigenvector $\mathbf{q}_1$ and its eigenvalue λ_1 are known, the next one can be reached by removing the first: put

$$\mathbf{A}' = \mathbf{A} - \lambda_1 \mathbf{q}_1 \mathbf{q}_1^*.$$

Let $\mathbf{q}_1, \dots, \mathbf{q}_n$ be an orthonormal eigenbasis (Corollary 11.4.3). Then $\mathbf{A}'\mathbf{q}_1 = \lambda_1 \mathbf{q}_1 - \lambda_1 \mathbf{q}_1 (\mathbf{q}_1^* \mathbf{q}_1) = \mathbf{0}$, and for $i \neq 1$, $\mathbf{A}'\mathbf{q}_i = \lambda_i \mathbf{q}_i - \lambda_1 \mathbf{q}_1 (\mathbf{q}_1^* \mathbf{q}_i) = \lambda_i \mathbf{q}_i$ by orthonormality. So $\mathbf{A}'$ is Hermitian with the same eigenvectors and the eigenvalue list $0, \lambda_2, \dots, \lambda_n$: the power method applied to $\mathbf{A}'$ finds λ_2, provided λ_2 is now dominant in modulus.

Warning. **Deflation is exact only with an exact eigenvector.** If the computed $\widehat{\mathbf{q}}_1$ differs from $\mathbf{q}_1$ by an angle η, then the matrix actually formed differs from the intended $\mathbf{A}'$ by $\lambda_1(\mathbf{q}_1\mathbf{q}_1^* - \widehat{\mathbf{q}}_1\widehat{\mathbf{q}}_1^*)$, of norm of order $|\lambda_1|\eta$, and by the perturbation bounds of Chapters 16 and 19 that error is inherited by every eigenvalue and eigenvector computed afterwards. Deflating $n-1$ times accumulates $n-1$ such errors. For one or two extreme eigenvalues deflation is the right tool; for the whole spectrum it is not, and the next section builds the algorithm that is.

Everything in this section has been a single vector chasing a single eigenvector. The next section iterates on a whole basis at once, and the result — the QR algorithm — turns out to be the power method in disguise, its accumulated factors furnishing a $\mathbf{QR}$ factorization of $\mathbf{A}^k$, with the shifts of this section reappearing as the device that makes it fast.

23.4.5 Exercises

23.4.5.1 A. Check your understanding

Exercise A1.

(a) State the two hypotheses of Theorem 23.4.1 on the eigenvalues and on the starting vector, and say what the rate ρ is.

(b) For a Hermitian $\mathbf{A}$, at what rate does the eigenvector converge and at what rate does the Rayleigh quotient? Which earlier result explains the relation between the two?

(c) Explain in one sentence why inverse iteration with shift μ finds the eigenvalue nearest μ.

(d) True or false: "the shifted matrix in inverse iteration is nearly singular, so the method is unreliable". Justify your answer.

(e) Give the per-step cost of the power method, of inverse iteration and of Rayleigh quotient iteration, for a dense $n \times n$ matrix.

Solution.

(a) The dominant eigenvalue must be strictly dominant **in modulus**, $|\lambda_1| > |\lambda_2|$, and the starting vector must have a non-zero coefficient c_1 on the corresponding eigenvector. The rate is $\rho = |\lambda_2/\lambda_1|$, the ratio of the two largest moduli.

(b) The eigenvector converges at rate ρ^k (Theorem 23.4.1 (a)) and the Rayleigh quotient at rate ρ^{2k} (Corollary 23.4.2). The relation is the second-order accuracy of the Rayleigh quotient at a Hermitian matrix, quantified by Theorem 19.6.2: a residual of size ε gives an eigenvalue error of at most ε^2 divided by the gap.

(c) Because $(\mathbf{A}-\mu\mathbf{I})^{-1}$ has the same eigenvectors as $\mathbf{A}$ and the eigenvalues $(\lambda_i-\mu)^{-1}$, whose moduli are largest precisely for the λ_i nearest μ (Theorem 23.4.3).

(d) False. The forward error in $\mathbf{z}^{(k)}$ is indeed large, but only its **direction** is used, and normalizing removes the part of the error that the ill-conditioning creates; the residual $\|\mathbf{A}\widehat{\mathbf{q}} - \mu\widehat{\mathbf{q}}\|$ of the normalized answer is small, and that is what certifies an eigenvector. The method is unreliable for a different reason — a small gap g — as the warning after Theorem 23.4.3 says.

(e) Power method: one matrix–vector product, $2n^2$ flops. Inverse iteration: one factorization of $\mathbf{A}-\mu\mathbf{I}$ by elimination with pivoting, $\frac{2}{3}n^3$, computed once, then $2n^2$ per step. Rayleigh quotient iteration: a new factorization every step, $\frac{2}{3}n^3$ per step — paid for by the cubic rate, which needs only three or four steps.

23.4.5.2 B. Practice

Exercise B1: A rate, read off the spectrum.

Let $\mathbf{A} = \left(\begin{smallmatrix} 4 & 1 \\ 2 & 3 \end{smallmatrix}\right)$.

(a) Find the eigenvalues and eigenvectors of $\mathbf{A}$, and the rate ρ of the power method.

(b) Starting from $\mathbf{x}^{(0)} = \mathbf{e}_1$, compute $\mathbf{A}^k\mathbf{e}_1$ in closed form and verify that the direction converges at rate ρ^k.

(c) How many steps are needed to gain six decimal digits?

Solution.

(a) $\operatorname{tr}\mathbf{A} = 7$ and $\det\mathbf{A} = 10$, so the eigenvalues are 5 and 2. For $\lambda = 5$: $(\mathbf{A} - 5\mathbf{I})\mathbf{v} = \mathbf{0}$ reads $-v_1 + v_2 = 0$, giving $\mathbf{v}_1 = (1, 1)$. For $\lambda = 2$: $2v_1 + v_2 = 0$, giving $\mathbf{v}_2 = (1, -2)$. Hence $\rho = \frac{2}{5}$.

(b) $\mathbf{e}_1 = \frac{2}{3}(1, 1) + \frac{1}{3}(1, -2)$, as one checks by adding. So

$$\mathbf{A}^k\mathbf{e}_1 = \tfrac{2}{3}5^k(1, 1) + \tfrac{1}{3}2^k(1, -2).$$

Dividing by $\frac{2}{3}5^k$ gives $(1, 1) + \frac{1}{2}(\frac{2}{5})^k(1, -2)$, so the distance from the direction $(1, 1)$ is a constant times $(\frac{2}{5})^k = \rho^k$, as Theorem 23.4.1 says.

(c) Each step multiplies the error by $\rho = 0.4$, that is by $10^{-\log_{10}(2.5)} = 10^{-0.398}$. Six digits need $6/0.398 = 15.1$ steps, so sixteen (and indeed $\rho^{15} = 1.1 \cdot 10^{-6}$, $\rho^{16} = 4.3 \cdot 10^{-7}$).

Exercise B2: Choosing a shift.

Let $\mathbf{A} = \operatorname{diag}(10, 3, 1)$.

(a) What is the rate of the plain power method?

(b) Find the rate of inverse iteration with shift $\mu = 0$, and say which eigenvector it finds.

(c) Find the rate of inverse iteration with shift $\mu = \frac{5}{2}$, and say which eigenvector it finds.

(d) Which shift would you choose to compute the middle eigenvalue as fast as possible, and what rate does it give? Explain why no shift gives a rate of 0.

Solution.

(a) By Theorem 23.4.1, $\rho = |3/10| = 0.3$, and the iterates converge to $\mathbf{e}_1$.

(b) With $\mu = 0$ the eigenvalue nearest 0 is 1, at distance 1; the next nearest is 3, at distance 3. So $\rho_\mu = \frac{1}{3}$, and the method finds $\mathbf{e}_3$. (Inverse iteration with shift 0 is the power method on $\mathbf{A}^{-1}$.)

(c) Distances from $\frac{5}{2}$ are 7.5, 0.5, 1.5. The nearest eigenvalue is 3, the next nearest 1, so $\rho_\mu = 0.5/1.5 = \frac{1}{3}$, and the method finds $\mathbf{e}_2$, the **middle** eigenvector — which the plain power method can never reach.

(d) Take $\mu = 3 + \delta$ with $0 < \delta < 1$: the distances are $7 - \delta$, δ, $2 + \delta$, so $\rho_\mu = \delta/(2 + \delta) \to 0$ as $\delta \to 0$. Any μ very close to 3 is excellent. No shift gives rate exactly 0, because $\mu = 3$ is an eigenvalue and Definition 23.4.2 then does not apply: $\mathbf{A} - 3\mathbf{I}$ is singular and there is nothing to solve with. The limiting case is not a fast method but no method — which is why Rayleigh quotient iteration, which walks the shift towards the eigenvalue, stops the moment it arrives.

Exercise B3: Deflating a symmetric matrix.

Let $\mathbf{A} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$.

(a) Write down $\mathbf{A}' = \mathbf{A} - 3\mathbf{q}_1\mathbf{q}_1^\top$ for the unit eigenvector $\mathbf{q}_1$ of the eigenvalue 3, and verify its eigenvalues directly.

(b) What does the power method of Theorem 23.4.1, applied to $\mathbf{A}'$ from $\mathbf{x}^{(0)} = \mathbf{e}_1$, produce, and at what rate?

(c) Explain why the answer to (b) makes deflation look better than it is.

Solution.

(a) $\mathbf{q}_1 = \frac{1}{\sqrt{2}}(1,1)$ and $\mathbf{q}_1\mathbf{q}_1^\top = \frac{1}{2}\left(\begin{smallmatrix}1&1\\1&1\end{smallmatrix}\right)$, so

$$\mathbf{A}' = \begin{pmatrix}2&1\\1&2\end{pmatrix} - \tfrac{3}{2}\begin{pmatrix}1&1\\1&1\end{pmatrix} = \tfrac{1}{2}\begin{pmatrix}1&-1\\-1&1\end{pmatrix}.$$

Then $\mathbf{A}'(1,1) = \mathbf{0}$ and $\mathbf{A}'(1,-1) = (1,-1)$: the eigenvalues are 0 and 1, as predicted, with the same eigenvectors.

(b) $\mathbf{A}'\mathbf{e}_1 = \frac{1}{2}(1,-1)$, which is already an eigenvector, so the power iteration of Definition 23.4.1 gives $\mathbf{x}^{(1)} = \frac{1}{\sqrt{2}}(1,-1)$ and every later iterate equals it: it converges in one step, with $\mu_1 = 1$ exactly.

(c) Because the deflation was exact. The eigenvector $\mathbf{q}_1 = \frac{1}{\sqrt{2}}(1,1)$ was known in closed form, so $\mathbf{A}'$ had the eigenvalue 0 exactly and the remaining eigenvector survived untouched. In a computation $\mathbf{q}_1$ is known only to within the accuracy of the first run, and by the warning after the deflation formula the error in $\mathbf{q}_1$ enters $\mathbf{A}'$ as a perturbation of size about $|\lambda_1|\eta$, which every later eigenpair inherits. One clean step here is not evidence about $n-1$ dirty ones.

23.4.5.3 C. Going deeper

Exercise C1: What the squaring really needs.

Let $\mathbf{A} \in M_n(F)$ be Hermitian with orthonormal eigenbasis $\mathbf{q}_1, \dots, \mathbf{q}_n$, and let $\mathbf{x}$ be a unit vector with $s = \|\mathbf{x} - \mathbf{q}_1\mathbf{q}_1^*\mathbf{x}\|$.

(a) Prove that $|R_{\mathbf{A}}(\mathbf{x}) - \lambda_1| \le s^2 \max_{i\neq 1}|\lambda_i - \lambda_1|$.

(b) Show by example that the corresponding statement for a non-Hermitian $\mathbf{A}$ is false: exhibit $\mathbf{A} \in M_2(\mathbb{C})$, an eigenvalue λ_1 with unit eigenvector $\mathbf{q}_1$, and unit vectors $\mathbf{x}$ with $s \to 0$ for which $|\mathbf{x}^*\mathbf{A}\mathbf{x} - \lambda_1|$ is **not** $O(s^2)$.

(c) Hence say which hypothesis of Theorem 23.4.4 the example violates, and which step of the proof breaks.

Solution.

(a) This is Step 1 of the proof of Theorem 23.4.4 with $j = 1$. Expanding $\mathbf{x} = \sum_i c_i\mathbf{q}_i$ with $\sum_i|c_i|^2 = 1$, we get $s^2 = \sum_{i\neq 1}|c_i|^2$ and, by Theorem 10.2.1 (b), $R_{\mathbf{A}}(\mathbf{x}) = \sum_i|c_i|^2\lambda_i$. Since the weights sum to 1,

$$R_{\mathbf{A}}(\mathbf{x}) - \lambda_1 = \sum_{i\neq 1}|c_i|^2(\lambda_i - \lambda_1),$$

whose modulus is at most $s^2 \max_{i\neq 1}|\lambda_i - \lambda_1|$.

(b) Take $\mathbf{A} = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, the standard non-diagonalizable example, with $\lambda_1 = 0$ and $\mathbf{q}_1 = \mathbf{e}_1$. Let $\mathbf{x} = (\sqrt{1-s^2},\, s)$ for small $s > 0$, a unit vector whose part orthogonal to $\mathbf{e}_1$ has length exactly s. Then

$$\mathbf{x}^*\mathbf{A}\mathbf{x} = \overline{x_1}x_2 = s\sqrt{1-s^2},$$

which is $s + O(s^3)$: **first** order in s, not second. So no bound of the form Cs^2 can hold as $s \to 0$.

(c) The example violates the hypothesis that $\mathbf{A}$ be Hermitian. The step that breaks is Step 1: for a Hermitian $\mathbf{A}$ the quantity $\mathbf{x}^*\mathbf{A}\mathbf{x}$ is the weighted average $\sum_i |c_i|^2\lambda_i$ of the eigenvalues, in which only the squared moduli of the coefficients appear and the first-order term is therefore absent. For a general $\mathbf{A}$ the cross terms $\overline{c_i}c_k\,\mathbf{q}_i^*\mathbf{A}\mathbf{q}_k$ with $i \neq k$ survive, and they are of first order in the small coefficients. With Step 1 weakened to $O(s)$, Step 3 multiplies s by $O(s)$ and the rate is quadratic, not cubic — which is the remark after Theorem 23.4.4.

Exercise C2: Two eigenvalues of equal modulus, over the reals.

Let $\mathbf{A} \in M_2(\mathbb{R})$ be the rotation matrix $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$.

(a) Find the eigenvalues of $\mathbf{A}$ and explain why Theorem 23.4.1 does not apply.

(b) Describe the power iteration from an arbitrary unit $\mathbf{x}^{(0)} \in \mathbb{R}^2$, and show that no line is a limit.

(c) Now take the shift $\mu = \frac{1}{2}$ and run inverse iteration over $\mathbb{C}$. Does the theorem apply? Compute ρ_μ. *Hint: the eigenvalues of* $\mathbf{A}$ *are* $\pm i$.

(d) Deduce a one-sentence moral about which of the two failures of Example (The method that never converges) a shift can repair.

Solution.

(a) $p_{\mathbf{A}}(x) = x^2 + 1$, so the eigenvalues are i and $-i$, both of modulus 1. The hypothesis $|\lambda_1| > |\lambda_2|$ fails.

(b) $\mathbf{A}$ is orthogonal, so $\|\mathbf{A}\mathbf{x}\| = \|\mathbf{x}\|$ and no normalization is needed: $\mathbf{x}^{(k)} = \mathbf{A}^k\mathbf{x}^{(0)}$. Since $\mathbf{A}^2 = -\mathbf{I}$, the iterates are $\mathbf{x}^{(0)}, \mathbf{A}\mathbf{x}^{(0)}, -\mathbf{x}^{(0)}, -\mathbf{A}\mathbf{x}^{(0)}, \mathbf{x}^{(0)}, \ldots$, of period 4, and the lines they span alternate between $\operatorname{span}(\mathbf{x}^{(0)})$ and $\operatorname{span}(\mathbf{A}\mathbf{x}^{(0)})$, which are distinct because $\mathbf{A}$ has no real eigenvector. A sequence taking two distinct values infinitely often has no limit.

(c) Over $\mathbb{C}$ the matrix is diagonalizable, with eigenvectors $(1, i)$ and $(1, -i)$. The shift $\mu = \frac{1}{2}$ is not an eigenvalue, and the distances are $|i - \frac{1}{2}| = |-i - \frac{1}{2}| = \sqrt{5}/2$ — **equal**. So there is no unique nearest eigenvalue and Theorem 23.4.3 still does not apply; $\rho_\mu = 1$. Any real shift fails in the same way, by symmetry in the conjugate pair; a shift such as $\mu = \frac{i}{2}$ does work, with distances $\frac{1}{2}$ and $\frac{3}{2}$ and $\rho_\mu = \frac{1}{3}$.

(d) A shift repairs a bad *rate* and a wrong *target*, by moving the origin from which moduli are measured; it cannot repair a tie, and over $\mathbb{R}$ a conjugate pair of eigenvalues is a tie that no real shift can break.

Exercise C3: A small residual certifies an eigenpair.

Let $\mathbf{A} \in M_n(\mathbb{C})$ be Hermitian with orthonormal eigenbasis $\mathbf{q}_1, \ldots, \mathbf{q}_n$, let $\widehat{\mathbf{q}}$ be a unit

vector, let $\widehat{\mu} = R_{\mathbf{A}}(\widehat{\mathbf{q}})$ and $\varepsilon = \|\mathbf{A}\widehat{\mathbf{q}} - \widehat{\mu}\widehat{\mathbf{q}}\|$. Suppose λ_j is the only eigenvalue of $\mathbf{A}$ in the interval $(\widehat{\mu} - g, \widehat{\mu} + g)$.

(a) Prove that $\|\widehat{\mathbf{q}} - \mathbf{q}_j\mathbf{q}_j^*\widehat{\mathbf{q}}\| \le \varepsilon/g$, assuming $\varepsilon < g$.

(b) Deduce a bound on $|\widehat{\mu} - \lambda_j|$ from Theorem 19.6.2, and compare it with the bound from Theorem 19.6.1.

(c) In the inverse iteration of Definition 23.4.2 with a backward stable solve, ε is about $1/\|\widehat{\mathbf{z}}\| + cu\|\mathbf{A} - \mu\mathbf{I}\|$. Explain what (a) then says about the computed direction, and in particular why the accuracy improves as the shift improves.

Solution.

(a) Expand $\widehat{\mathbf{q}} = \sum_i d_i\mathbf{q}_i$ with $\sum_i |d_i|^2 = 1$. Then $\mathbf{A}\widehat{\mathbf{q}} - \widehat{\mu}\widehat{\mathbf{q}} = \sum_i d_i(\lambda_i - \widehat{\mu})\mathbf{q}_i$, so by Theorem 10.2.1 (c),

$$\varepsilon^2 = \sum_i |d_i|^2(\lambda_i - \widehat{\mu})^2 \;\ge\; \sum_{i\ne j} |d_i|^2(\lambda_i - \widehat{\mu})^2 \;\ge\; g^2 \sum_{i\ne j} |d_i|^2,$$

because every λ_i with $i \ne j$ lies outside $(\widehat{\mu} - g, \widehat{\mu} + g)$. Since $\|\widehat{\mathbf{q}} - \mathbf{q}_j\mathbf{q}_j^*\widehat{\mathbf{q}}\|^2 = \sum_{i\ne j}|d_i|^2$, taking square roots gives the bound.

(b) Theorem 19.6.1 gives an eigenvalue within ε of $\widehat{\mu}$, and by hypothesis the only candidate in that range (once $\varepsilon < g$) is λ_j, so $|\widehat{\mu} - \lambda_j| \le \varepsilon$. Theorem 19.6.2, applied with $\alpha = \widehat{\mu} - g$ and $\beta = \widehat{\mu} + g$, improves this to

$$|\widehat{\mu} - \lambda_j| \le \frac{\varepsilon^2}{g},$$

which is smaller by a factor ε/g — the quadratic gain of the Rayleigh quotient once more.

(c) It says that the **direction** of the computed $\widehat{\mathbf{z}}$ is within ε/g of $\mathbf{q}_j$, whatever the relative error in $\widehat{\mathbf{z}}$ itself. As the shift μ approaches λ_j, the matrix $\mathbf{A} - \mu\mathbf{I}$ becomes more nearly singular, and — provided the right-hand side $\mathbf{x}^{(k)}$ has a component along $\mathbf{q}_j$ that is not small, by the bound $\|\widehat{\mathbf{z}}\| \ge |\mathbf{q}_j^*\mathbf{x}^{(k)}|/(|\lambda_j - \mu| + \|\mathbf{\Delta}\|)$ established in the discussion following Theorem 23.4.3 — $\|\widehat{\mathbf{z}}\|$ grows like $1/|\lambda_j - \mu|$. So the first part of ε shrinks in proportion, and the second part is already at the rounding level. **A worse-conditioned system gives a better answer**, because the quantity that grows is the one in the denominator. What the bound never forgives is a small g: two nearby eigenvalues leave ε/g large no matter how good the shift is.

23.5 The QR Algorithm

Chapter 10 §08 brought a square matrix to upper Hessenberg form with reflections and then stopped, with a warning attached: no finite procedure built from arithmetic and square roots can carry that reduction on to triangular form, because such a procedure would extract the roots of an arbitrary polynomial from its coefficients, and the theorem of Abel and Ruffini forbids it — a theorem this book quotes, there and here, and does not prove. Every eigenvalue method must therefore iterate, and nothing proved below rests on that quotation. The iteration this section develops is the one Chapter 10 named in a single sentence — factor $\mathbf{Z} = \mathbf{QR}$, then replace $\mathbf{Z}$ by

RQ — and we now ask why it works, why it is always started from a Hessenberg matrix, and why it is always run with a shift.

23.5.1 Factor and multiply back

Section 4 iterated a matrix against a **vector**: the power method drives $\mathbf{x}^{(k)} = \mathbf{A}\mathbf{x}^{(k-1)}$ towards the dominant eigenvector, one eigenvalue at a time. The whole spectrum at once needs an iteration on **matrices**, and it must be an iteration by similarity, or the spectrum would not survive it. Chapter 10's reflections already gave us a supply of similarities that cost little: $\mathbf{A} \mapsto \mathbf{Q}^*\mathbf{A}\mathbf{Q}$ with $\mathbf{Q}$ unitary. The question is which $\mathbf{Q}$ to take.

Here is the answer, and it looks like sleight of hand. Factor $\mathbf{A} = \mathbf{Q}\mathbf{R}$ and then multiply the two factors back **in the other order**. Since $\mathbf{Q}^*\mathbf{Q} = \mathbf{I}$, the product $\mathbf{R}\mathbf{Q}$ is $\mathbf{Q}^*(\mathbf{Q}\mathbf{R})\mathbf{Q} = \mathbf{Q}^*\mathbf{A}\mathbf{Q}$, so nothing has been lost; and the reversal shifts weight from the upper triangle into the lower one in a way that, repeated, empties the lower triangle altogether.

Factor the matrix, then put the factors back the wrong way round, and repeat.

Definition 23.5.1 — The QR Iteration

Let $\mathbf{A} \in M_n(F)$, where $F = \mathbb{R}$ or $F = \mathbb{C}$. Set $\mathbf{A}^{(1)} = \mathbf{A}$, and for $k \geq 1$ define

$$\mathbf{A}^{(k)} = \mathbf{Q}^{(k)}\mathbf{R}^{(k)}, \qquad \mathbf{A}^{(k+1)} = \mathbf{R}^{(k)}\mathbf{Q}^{(k)},$$

where $\mathbf{A}^{(k)} = \mathbf{Q}^{(k)}\mathbf{R}^{(k)}$ is **a** factorization with $\mathbf{Q}^{(k)} \in M_n(F)$ unitary and $\mathbf{R}^{(k)} \in M_n(F)$ upper triangular. The sequence $\mathbf{A}^{(1)}, \mathbf{A}^{(2)}, \ldots$ is the **unshifted QR iteration** started at $\mathbf{A}$.

In words: at every step we factor the current matrix, then form the product of its factors in the reversed order, and that product is the next matrix. The superscript in parentheses counts steps, never coordinates.

Well-definedness. A factorization exists at every step, for every square matrix and with no hypothesis on its columns, by Theorem 10.8.4. It need not be unique: if $\mathbf{D}$ is diagonal with $|d_j| = 1$, then $(\mathbf{Q}\mathbf{D})(\mathbf{D}^*\mathbf{R})$ is another one. When $\mathbf{A}^{(k)}$ is **invertible** the ambiguity is exactly that, and demanding a positive real diagonal in $\mathbf{R}^{(k)}$ removes it, by Theorem 10.8.1; and if $\mathbf{A}$ is invertible then so is every $\mathbf{A}^{(k)}$, being similar to $\mathbf{A}$. We do not need the normalization for anything below, so the definition leaves the choice open.

Proposition 23.5.1 — Every Step Is a Unitary Similarity

In the notation of Definition 23.5.1, $\mathbf{A}^{(k+1)} = (\mathbf{Q}^{(k)})^*\mathbf{A}^{(k)}\mathbf{Q}^{(k)}$ for every k. Consequently all the matrices $\mathbf{A}^{(k)}$ are unitarily similar to $\mathbf{A}$, and they share its characteristic polynomial, its eigenvalues with multiplicities, its trace and its determinant.

Proof. Since $\mathbf{Q}^{(k)}$ is unitary, $(\mathbf{Q}^{(k)})^*\mathbf{Q}^{(k)} = \mathbf{I}_n$ (Definition 10.7.2), so

$$(\mathbf{Q}^{(k)})^*\mathbf{A}^{(k)}\mathbf{Q}^{(k)} = (\mathbf{Q}^{(k)})^*\mathbf{Q}^{(k)}\mathbf{R}^{(k)}\mathbf{Q}^{(k)} = \mathbf{R}^{(k)}\mathbf{Q}^{(k)} = \mathbf{A}^{(k+1)}.$$

A unitary matrix is invertible with $\mathbf{Q}^{-1} = \mathbf{Q}^*$, so this exhibits $\mathbf{A}^{(k+1)}$ as similar to $\mathbf{A}^{(k)}$

(Definition 3.7.2); composing these similarities for $1, \dots, k-1$ makes $\mathbf{A}^{(k)}$ similar to $\mathbf{A}^{(1)} = \mathbf{A}$. Similar matrices have the same characteristic polynomial (Theorem 6.10.3), hence the same eigenvalues with multiplicities, and the same trace and determinant. This proves the proposition.

■

Two examples fix what the iteration does and does not do.

Example. (Two matrices the iteration cannot move)

Determine the QR iterates of $\mathbf{A} = \operatorname{diag}(3, 1)$ and of the rotation $\mathbf{B} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$.

Solution. For $\mathbf{A}$: the factorization $\mathbf{A} = \mathbf{I}_2\mathbf{A}$ has $\mathbf{I}_2$ unitary and $\mathbf{A}$ upper triangular with positive diagonal, so by the uniqueness in Theorem 10.8.1 it is *the* factorization. Then $\mathbf{A}^{(2)} = \mathbf{A}\mathbf{I}_2 = \mathbf{A}$, and the iteration stands still. It has nothing to do: $\mathbf{A}$ is already triangular and its diagonal already lists the eigenvalues (Theorem 8.7.4).

For $\mathbf{B}$: here $\mathbf{B}$ is itself unitary, since its columns $(0, 1)$ and $(-1, 0)$ are orthonormal, so $\mathbf{B} = \mathbf{B}\,\mathbf{I}_2$ is a factorization with $\mathbf{I}_2$ upper triangular with positive diagonal — again the unique one. So $\mathbf{B}^{(2)} = \mathbf{I}_2\mathbf{B} = \mathbf{B}$, and the iteration stands still here too. This time it has everything to do: the eigenvalues of $\mathbf{B}$ are $\pm i$, and $\mathbf{B}$ is not triangular. The iteration is stuck.

The second matrix is the section's standing negative example, and the reason it is stuck is visible already: $|i| = |-i|$. We return to it after the convergence theorem, and repair it with a shift.

Warning. **Reversing the factors is not a similarity for just any factorization.** The step works because $\mathbf{Q}$ is unitary, so that $\mathbf{Q}^{-1} = \mathbf{Q}^*$ and $\mathbf{RQ} = \mathbf{Q}^*\mathbf{AQ}$. Do the same with an Ł**U** factorization and you get $\mathbf{U}$Ł $= \text{Ł}^{-1}\mathbf{A}$Ł, which is still a similarity — but with Ł^{-1} in place of Ł*, and Ł^{-1} can be enormous. That is the older Ł**R** iteration, and its instability under rounding is exactly the instability of elimination without pivoting met in Section 2.

23.5.2 The iteration is the power method in disguise

Nothing said so far suggests that the iterates go anywhere. The identity that explains them is the following, and it is the heart of the section: *the accumulated factors of k steps are a QR factorization of the k-th power of* $\mathbf{A}$. Powers of $\mathbf{A}$ are what the power method of Section 4 runs on, so the identity says the two methods are the same method, one applied to a vector and the other to a whole basis at once.

Write

$$\mathbf{U}_k = \mathbf{Q}^{(1)}\mathbf{Q}^{(2)} \cdots \mathbf{Q}^{(k)}, \qquad \mathbf{T}_k = \mathbf{R}^{(k)} \cdots \mathbf{R}^{(2)}\mathbf{R}^{(1)}.$$

The first is unitary, as a product of unitary matrices (Proposition 10.7.4), and the second is upper triangular, as a product of upper triangular matrices.

Theorem 23.5.2 — QR Iterates Factor the Powers

Let $\mathbf{A} \in M_n(F)$ and let $\mathbf{A}^{(k)}$, $\mathbf{Q}^{(k)}$, $\mathbf{R}^{(k)}$ be as in Definition 23.5.1. Then for every $k \geq 1$,

$$\mathbf{A}^{(k+1)} = \mathbf{U}_k^* \, \mathbf{A} \, \mathbf{U}_k \qquad \text{and} \qquad \mathbf{A}^k = \mathbf{U}_k \mathbf{T}_k.$$

In particular $\mathbf{U}_k \mathbf{T}_k$ is a QR factorization of $\mathbf{A}^k$.

Idea. Induction on k, with the two statements proved together, because each feeds the other. The similarity statement is Proposition 23.5.1 telescoped. For the factorization, the move to find is the one that turns $\mathbf{A}\mathbf{U}_k$ into something with a $\mathbf{Q}$ at the front: the similarity statement, read backwards, says $\mathbf{A}\mathbf{U}_k = \mathbf{U}_k \mathbf{A}^{(k+1)}$, and $\mathbf{A}^{(k+1)}$ is by definition $\mathbf{Q}^{(k+1)}\mathbf{R}^{(k+1)}$. One line of bookkeeping then converts $\mathbf{A} \cdot \mathbf{A}^k$ into $\mathbf{U}_{k+1}\mathbf{T}_{k+1}$.

Proof. Both statements by induction on k.

For $k = 1$: $\mathbf{U}_1 = \mathbf{Q}^{(1)}$ and $\mathbf{T}_1 = \mathbf{R}^{(1)}$, so $\mathbf{U}_1\mathbf{T}_1 = \mathbf{Q}^{(1)}\mathbf{R}^{(1)} = \mathbf{A}^{(1)} = \mathbf{A}$, and $\mathbf{U}_1^*\mathbf{A}\mathbf{U}_1 = \mathbf{A}^{(2)}$ by Proposition 23.5.1.

Let $k \geq 1$ and suppose both statements hold for k. By Proposition 23.5.1 applied at step $k+1$ and the inductive hypothesis,

$$\mathbf{A}^{(k+2)} = (\mathbf{Q}^{(k+1)})^* \mathbf{A}^{(k+1)} \mathbf{Q}^{(k+1)} = (\mathbf{Q}^{(k+1)})^* \mathbf{U}_k^* \mathbf{A} \, \mathbf{U}_k \mathbf{Q}^{(k+1)} = \mathbf{U}_{k+1}^* \mathbf{A} \, \mathbf{U}_{k+1},$$

where the last equality uses $\mathbf{U}_{k+1} = \mathbf{U}_k \mathbf{Q}^{(k+1)}$ and $(\mathbf{X}\mathbf{Y})^* = \mathbf{Y}^*\mathbf{X}^*$. That is the first statement for $k+1$.

For the second, multiply the inductive similarity $\mathbf{A}^{(k+1)} = \mathbf{U}_k^*\mathbf{A}\mathbf{U}_k$ on the left by $\mathbf{U}_k$, which is legitimate because $\mathbf{U}_k\mathbf{U}_k^* = \mathbf{I}_n$:

$$\mathbf{A} \, \mathbf{U}_k = \mathbf{U}_k \mathbf{A}^{(k+1)} = \mathbf{U}_k \mathbf{Q}^{(k+1)} \mathbf{R}^{(k+1)} = \mathbf{U}_{k+1} \mathbf{R}^{(k+1)}.$$

Hence, using the inductive factorization $\mathbf{A}^k = \mathbf{U}_k\mathbf{T}_k$,

$$\mathbf{A}^{k+1} = \mathbf{A} \, (\mathbf{U}_k \mathbf{T}_k) = (\mathbf{A} \, \mathbf{U}_k)\mathbf{T}_k = \mathbf{U}_{k+1}\mathbf{R}^{(k+1)}\mathbf{T}_k = \mathbf{U}_{k+1}\mathbf{T}_{k+1},$$

since $\mathbf{T}_{k+1} = \mathbf{R}^{(k+1)}\mathbf{T}_k$ by definition. As $\mathbf{U}_{k+1}$ is unitary and $\mathbf{T}_{k+1}$ upper triangular, this is a QR factorization of $\mathbf{A}^{k+1}$, and the induction is complete. ∎

The consequence to keep is about the **first column**. Comparing first columns in $\mathbf{A}^k = \mathbf{U}_k\mathbf{T}_k$ and writing $\tau_k = (\mathbf{T}_k)_{11}$, we get

$$\mathbf{A}^k \mathbf{e}_1 = \mathbf{U}_k \mathbf{T}_k \mathbf{e}_1 = \tau_k \, \mathbf{U}_k \mathbf{e}_1, \tag{23.5.1}$$

because the first column of an upper triangular matrix is $\tau_k \mathbf{e}_1$. So whenever $\tau_k \neq 0$, which the Quick check just below records for invertible $\mathbf{A}$, the first column of $\mathbf{U}_k$ is the normalized vector $\mathbf{A}^k\mathbf{e}_1 / \|\mathbf{A}^k\mathbf{e}_1\|$, up to a scalar of modulus one — which is precisely the k-th iterate of the power method (Theorem 23.4.1) started at $\mathbf{e}_1$. The QR algorithm runs the power method in its first column, and, as the next theorem shows, that alone forces the first column of $\mathbf{A}^{(k+1)}$ to converge.

Quick check. Why is $\tau_k \neq 0$ when $\mathbf{A}$ is invertible?

Solution. Each $\mathbf{A}^{(j)}$ is similar to $\mathbf{A}$ (Proposition 23.5.1), hence invertible, and $\mathbf{R}^{(j)} = (\mathbf{Q}^{(j)})^* \mathbf{A}^{(j)}$ is then invertible as a product of invertible matrices. So $\mathbf{T}_k$ is invertible, being a product of invertible matrices; an upper triangular matrix is invertible exactly when its diagonal entries are all non-zero (Lemma 2.6.2), so $\tau_k = (\mathbf{T}_k)_{11} \neq 0$.

23.5.3 What converges, and how fast

Theorem 23.5.3 — Convergence of the First Column

Let $\mathbf{A} \in M_n(\mathbb{C})$ be invertible and diagonalizable, say $\mathbf{A} = \mathbf{X}\mathbf{\Lambda}\mathbf{X}^{-1}$ with $\mathbf{\Lambda} = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$ and with $\mathbf{v}_1, \dots, \mathbf{v}_n$ the columns of $\mathbf{X}$. Assume a **single dominant eigenvalue**,

$$|\lambda_1| > |\lambda_2| \geq \cdots \geq |\lambda_n| > 0,$$

and write $\mathbf{e}_1 = c_1\mathbf{v}_1 + \cdots + c_n\mathbf{v}_n$, assuming $c_1 \neq 0$. Put $t = |\lambda_2/\lambda_1| < 1$. Then there is a constant C, depending on $\mathbf{A}$ and $\mathbf{X}$ but not on k, such that the unshifted QR iterates satisfy

$$\|\mathbf{A}^{(k+1)}\mathbf{e}_1 - \lambda_1 \mathbf{e}_1\|_2 \leq C\, t^k \qquad (k \geq 1).$$

In particular $a_{11}^{(k)} \to \lambda_1$ and $a_{i1}^{(k)} \to 0$ for every $i \geq 2$, each at the rate t^k. For $n = 2$ this says that the iterates converge to upper triangular form, with $a_{11}^{(k)} \to \lambda_1$ and $a_{22}^{(k)} \to \lambda_2$.

Idea. By Eq. 23.5.1 the first column $\mathbf{u}_1$ of $\mathbf{U}_k$ is the power-method iterate, so it is close to the dominant eigenvector, and the vector $\mathbf{A}\mathbf{u}_1 - \lambda_1\mathbf{u}_1$ is small. Now read $\mathbf{A}^{(k+1)} = \mathbf{U}_k^*\mathbf{A}\mathbf{U}_k$ column by column: its first column is $\mathbf{U}_k^*\mathbf{A}\mathbf{u}_1$, and subtracting $\lambda_1\mathbf{e}_1 = \mathbf{U}_k^*(\lambda_1\mathbf{u}_1)$ leaves $\mathbf{U}_k^*(\mathbf{A}\mathbf{u}_1 - \lambda_1\mathbf{u}_1)$. A unitary matrix does not change lengths, so the whole error in the first column *equals* the length of that small vector. Nothing else is needed.

Proof. Write $\mathbf{u}_1 = \mathbf{U}_k\mathbf{e}_1$ for the first column of $\mathbf{U}_k$, suppressing k from the notation.

Step 1: the error in the first column is a residual. Since $\mathbf{U}_k$ is unitary and $\mathbf{A}^{(k+1)} = \mathbf{U}_k^*\mathbf{A}\mathbf{U}_k$ by Theorem 23.5.2,

$$\mathbf{A}^{(k+1)}\mathbf{e}_1 - \lambda_1\mathbf{e}_1 = \mathbf{U}_k^*\mathbf{A}\mathbf{u}_1 - \lambda_1\mathbf{U}_k^*\mathbf{u}_1 = \mathbf{U}_k^*\big(\mathbf{A}\mathbf{u}_1 - \lambda_1\mathbf{u}_1\big),$$

using $\mathbf{u}_1 = \mathbf{U}_k\mathbf{e}_1$ twice. A unitary matrix preserves the Euclidean norm (Theorem 10.7.3), so

$$\|\mathbf{A}^{(k+1)}\mathbf{e}_1 - \lambda_1\mathbf{e}_1\|_2 = \|\mathbf{A}\mathbf{u}_1 - \lambda_1\mathbf{u}_1\|_2. \tag{$*$}$$

Step 2: $\mathbf{u}_1$ is a power-method iterate. By Eq. 23.5.1, $\mathbf{A}^k\mathbf{e}_1 = \tau_k\mathbf{u}_1$ with $\tau_k \neq 0$, as the Quick check above records. Since $\mathbf{A}\mathbf{v}_i = \lambda_i\mathbf{v}_i$,

$$\mathbf{A}^k\mathbf{e}_1 = \sum_{i=1}^{n} c_i\lambda_i^k\mathbf{v}_i = c_1\lambda_1^k\big(\mathbf{v}_1 + \mathbf{z}_k\big), \qquad \mathbf{z}_k = \sum_{i\geq 2}\frac{c_i}{c_1}\Big(\frac{\lambda_i}{\lambda_1}\Big)^k\mathbf{v}_i,$$

which is legitimate because $c_1 \neq 0$ and $\lambda_1 \neq 0$. Every ratio obeys $|\lambda_i/\lambda_1| \leq t$, so

$$\|\mathbf{z}_k\|_2 \leq M t^k, \qquad M = \sum_{i \geq 2} \frac{|c_i|}{|c_1|} \|\mathbf{v}_i\|_2,$$

by the triangle inequality (Corollary 10.1.6). Put $\mathbf{y}_k = \mathbf{v}_1 + \mathbf{z}_k$. Then $\mathbf{u}_1 = \mathbf{A}^k \mathbf{e}_1/\tau_k = \omega_k \, \mathbf{y}_k/\|\mathbf{y}_k\|_2$ for the scalar $\omega_k = c_1 \lambda_1^k \|\mathbf{y}_k\|_2/\tau_k$, and $|\omega_k| = 1$ because $\|\mathbf{u}_1\|_2 = 1$.

Step 3: the residual is small. Since $\mathbf{A}\mathbf{v}_1 = \lambda_1 \mathbf{v}_1$, the vector $\mathbf{v}_1$ drops out of $(\mathbf{A} - \lambda_1 \mathbf{I})\mathbf{y}_k$, leaving

$$\mathbf{A}\mathbf{u}_1 - \lambda_1 \mathbf{u}_1 = \omega_k \, \frac{(\mathbf{A} - \lambda_1 \mathbf{I})\mathbf{z}_k}{\|\mathbf{y}_k\|_2},$$

$$\text{so} \qquad \|\mathbf{A}\mathbf{u}_1 - \lambda_1 \mathbf{u}_1\|_2 \leq \frac{\big(\|\mathbf{A}\|_2 + |\lambda_1|\big) M \, t^k}{\|\mathbf{y}_k\|_2}.$$

Choose k_0 with $M t^{k_0} \leq \frac{1}{2}\|\mathbf{v}_1\|_2$, possible because $t < 1$. For $k \geq k_0$ the triangle inequality gives $\|\mathbf{y}_k\|_2 \geq \|\mathbf{v}_1\|_2 - M t^k \geq \frac{1}{2}\|\mathbf{v}_1\|_2 > 0$, whence

$$\|\mathbf{A}\mathbf{u}_1 - \lambda_1 \mathbf{u}_1\|_2 \leq C_1 t^k, \qquad C_1 = \frac{2\big(\|\mathbf{A}\|_2 + |\lambda_1|\big) M}{\|\mathbf{v}_1\|_2}.$$

For the finitely many $k < k_0$ the crude bound $\|\mathbf{A}\mathbf{u}_1 - \lambda_1 \mathbf{u}_1\|_2 \leq \|\mathbf{A}\|_2 + |\lambda_1|$ holds, since $\|\mathbf{u}_1\|_2 = 1$. So the displayed estimate holds for all $k \geq 1$ with

$$C = \max\Big\{ C_1, \ \big(\|\mathbf{A}\|_2 + |\lambda_1|\big) t^{-k_0} \Big\},$$

and combining with $(*)$ proves the main estimate. The entrywise statements follow because each coordinate of a vector is at most its Euclidean norm.

For $n = 2$, the estimate forces $a_{21}^{(k)} \to 0$ and $a_{11}^{(k)} \to \lambda_1$; and $a_{22}^{(k)} = \operatorname{tr} \mathbf{A}^{(k)} - a_{11}^{(k)} = \lambda_1 + \lambda_2 - a_{11}^{(k)} \to \lambda_2$, the trace being preserved by Proposition 23.5.1. This proves the theorem.

■

What is proved here, and what is not. The theorem above settles the first column, for every n, and with it the whole 2×2 case. The general statement is this: if $\mathbf{A}$ is diagonalizable with $|\lambda_1| > |\lambda_2| > \cdots > |\lambda_n| > 0$, **and** if $\mathbf{X}^{-1}$ admits an $\mathbf{LU}$ factorization without row swaps (Theorem 2.6.4), then the whole of $\mathbf{A}^{(k)}$ below the diagonal tends to zero, with

$$a_{i+1,i}^{(k)} = O\big(|\lambda_{i+1}/\lambda_i|^k\big) \quad \text{and} \quad a_{ii}^{(k)} \to \lambda_i \quad (1 \leq i \leq n).$$

This is the classical convergence theorem of the algorithm, due to Rutishauser, Francis and Kublanovskaya; **it is not proved here.** The proof runs through the factorization $\mathbf{A}^k = \mathbf{X}\mathbf{\Lambda}^k \mathbf{L}\mathbf{U}$ of Theorem 23.5.2's identity, the observation that $\mathbf{\Lambda}^k \mathbf{L} \mathbf{\Lambda}^{-k} \to \mathbf{I}$, and a continuity argument for the QR factorization that this book has not developed. Nothing in this section or later depends on it: the Hessenberg and shifting results below are proved outright, and the worked example at the end exhibits the rates rather than assuming them. The extra hypothesis on $\mathbf{X}^{-1}$ is not cosmetic, and the strict ordering of the moduli is not either — the next example shows what happens without it.

Example. (The unshifted algorithm on a rotation)

Let $\mathbf{B} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. Explain why no unshifted QR iteration can bring $\mathbf{B}$ closer to triangular form, and say which hypothesis of Theorem 23.5.3 fails.

Solution. By Example (Two matrices the iteration cannot move), $\mathbf{B}^{(k)} = \mathbf{B}$ for every k: the iteration is stationary, and $\mathbf{B}$ is as far from triangular as a 2×2 matrix can be, with $b_{21} = 1$. The eigenvalues are $\pm i$, so $|\lambda_1| = |\lambda_2| = 1$ and the hypothesis $|\lambda_1| > |\lambda_2|$ fails. The failure is not an artifact of the proof. Over $\mathbb{R}$ the matrix is orthogonally similar to no real triangular matrix at all, since a real triangular matrix has real eigenvalues; and over $\mathbb{C}$ the power method has nothing to converge to, because $\mathbf{B}^k\mathbf{e}_1$ simply rotates around the plane forever (Theorem 23.4.1).

Warning. **Convergence is to triangular form, not to diagonal form.** Even when the iterates do converge, the strictly upper triangular part generally does not: only the entries **below** the diagonal die out. What is more, in the convergence theorem quoted above — the one this section does not prove — the order in which the eigenvalues appear on the diagonal is decided by the moduli, largest first, so that a run it covers reveals λ_1 in the top-left corner and λ_n in the bottom-right. With shifts, which is how the algorithm is actually run, even that ordering goes away.

23.5.4 Hessenberg first

As written, one step costs a QR factorization of a full $n \times n$ matrix and a matrix product: that is $O(n^3)$ flops, in the counting convention of Proposition 23.2.3, and the count really does grow like n^3, since the product alone touches n^2 entries with n terms each. The iteration needs many steps, and no amount of cleverness about the steps rescues a method that spends n^3 operations on each of them.

The remedy is Chapter 10's. Reduce $\mathbf{A}$ once to upper Hessenberg form by Theorem 10.8.5, at a cost of $O(n^3)$ paid a single time, and then iterate. This pays off only if the pattern survives the step, which is the content of the next proposition — and it is the sentence Chapter 10 §08 closed on: "Chapter 23 develops that iteration and explains why every implementation starts with the reduction proved here."

Proposition 23.5.4 — A QR Step Preserves Hessenberg Form

Let $\mathbf{Z} \in M_n(\mathbb{R})$ be upper Hessenberg, $n \geq 2$. Then $\mathbf{Z}$ has a factorization $\mathbf{Z} = \mathbf{QR}$ with $\mathbf{Q}$ orthogonal and $\mathbf{R}$ upper triangular in which $\mathbf{Q}$ is a product of $n - 1$ Givens rotations and is **itself upper Hessenberg**; and for this factorization $\mathbf{RQ}$ is again upper Hessenberg. Producing $\mathbf{R}$ and then $\mathbf{RQ}$ costs about $6n^2$ flops.

Idea. A Hessenberg matrix has only $n - 1$ entries in the way of triangularity, one per column, and Definition 10.8.2 removes one entry per rotation. So the natural factorization to use is the rotation one, not the reflection one — this is the case Chapter 10 §08 flagged, where "the count reverses". Then two bookkeeping facts finish it: the accumulated product of the rotations is Hessenberg, and upper triangular times upper

Hessenberg is upper Hessenberg.

Proof. For $1 \le i \le n-1$ let $\mathbf{G}_i = \mathbf{G}(i, i+1; c_i, s_i)$ be a Givens rotation in the coordinates $i, i+1$ (Definition 10.8.2). Working left to right, choose $\mathbf{G}_i$ to annihilate the entry in position $(i+1, i)$ of the matrix produced so far: if that matrix has entries a in position (i, i) and b in position $(i+1, i)$ with $(a, b) \neq (0, 0)$, take $c_i = a/r$ and $s_i = b/r$ with $r = \sqrt{a^2 + b^2}$, as in Chapter 10 §08; if $(a, b) = (0, 0)$, take $\mathbf{G}_i = \mathbf{I}_n$. This is the only entry below the diagonal in column i: the entries in rows $i+2, \dots, n$ of that column were zero in $\mathbf{Z}$, because $\mathbf{Z}$ is upper Hessenberg, and the earlier rotations $\mathbf{G}_1, \dots, \mathbf{G}_{i-1}$ touch only rows $1, \dots, i$. Left multiplication by $\mathbf{G}_i$ recombines rows i and $i+1$ only, so it cannot disturb the zeros already created: in a column $j \le i-1$ both of the rows being combined are already zero, since $i \ge j+1$. Hence

$$\mathbf{R} = \mathbf{G}_{n-1} \cdots \mathbf{G}_1 \mathbf{Z}$$

is upper triangular, and $\mathbf{Z} = \mathbf{Q}\mathbf{R}$ with $\mathbf{Q} = \mathbf{G}_1^\top \mathbf{G}_2^\top \cdots \mathbf{G}_{n-1}^\top$, orthogonal as a product of orthogonal matrices.

Claim. $\mathbf{P}_m = \mathbf{G}_1^\top \cdots \mathbf{G}_m^\top$ is upper Hessenberg for $1 \le m \le n-1$, and its columns $m+2, \dots, n$ are $\mathbf{e}_{m+2}, \dots, \mathbf{e}_n$.

Proof. Induction on m. Each $\mathbf{G}_i^\top$ fixes $\mathbf{e}_j$ for $j \notin \{i, i+1\}$, so $\mathbf{P}_m \mathbf{e}_j = \mathbf{e}_j$ whenever $j > m+1$, which is the second assertion. For $m = 1$, $\mathbf{P}_1 = \mathbf{G}_1^\top$ differs from $\mathbf{I}_n$ only in rows and columns $1, 2$, so its only non-zero entry below the diagonal is in position $(2, 1)$, and it is upper Hessenberg. Let $m \ge 2$ and suppose the claim holds for $m-1$. Right multiplication by $\mathbf{G}_m^\top$ changes only columns m and $m+1$, replacing them by the two combinations

$$c_m \mathbf{P}_{m-1}\mathbf{e}_m + s_m \mathbf{P}_{m-1}\mathbf{e}_{m+1} \quad \text{and} \quad -s_m \mathbf{P}_{m-1}\mathbf{e}_m + c_m \mathbf{P}_{m-1}\mathbf{e}_{m+1}.$$

By the inductive hypothesis $\mathbf{P}_{m-1}\mathbf{e}_m$ has zero entries in rows $m+2, \dots, n$, being column m of an upper Hessenberg matrix, and $\mathbf{P}_{m-1}\mathbf{e}_{m+1} = \mathbf{e}_{m+1}$ since $m+1 > (m-1)+1$. So both combinations vanish in rows $m+2, \dots, n$. Column m of $\mathbf{P}_m$ therefore vanishes below row $m+1$, as an upper Hessenberg matrix requires; and column $m+1$ vanishes below row $m+1$, which is more than required. All other columns are unchanged, so $\mathbf{P}_m$ is upper Hessenberg.

■

By the Claim, $\mathbf{Q} = \mathbf{P}_{n-1}$ is upper Hessenberg. Finally,

$$(\mathbf{R}\mathbf{Q})_{pq} = \sum_k r_{pk} q_{kq}$$

has a non-zero term only when $k \ge p$, because $\mathbf{R}$ is upper triangular, and $k \le q+1$, because $\mathbf{Q}$ is upper Hessenberg; together these force $p \le q+1$. So $\mathbf{R}\mathbf{Q}$ is upper Hessenberg.

Cost. Rotation $\mathbf{G}_i$ alters rows $i, i+1$ in columns $i, \dots, n$ only, since in the earlier columns both of those rows are already zero: that is $n-i+1$ pairs of entries, each pair replaced by two combinations of two terms, so $6(n-i+1)$ flops. Summing over $i = 1, \dots, n-1$ gives $3n^2 + O(n)$. Forming $\mathbf{R}\mathbf{Q} = \mathbf{R}\,\mathbf{G}_1^\top \cdots \mathbf{G}_{n-1}^\top$ applies $\mathbf{G}_i^\top$ on the right to columns

$i, i+1$ of the matrix built so far, and the same induction as in the Claim shows that those two columns vanish below row $i+1$; so $6(i+1)$ flops suffice, and summing gives $3n^2 + O(n)$ again. The total is $6n^2 + O(n)$, which proves the proposition.

■

So the reduction is done once, for $O(n^3)$, and every subsequent step costs $O(n^2)$ — a saving of a factor of n on each of the many steps. That is the whole reason every implementation begins with Theorem 10.8.5.

Remark. The proposition is stated over $\mathbb{R}$ because Definition 10.8.2 is. Over $\mathbb{C}$ one uses the complex rotations described in Chapter 10 §08 and the argument is unchanged. The conclusion also does not depend on which QR factorization is used, as long as $\mathbf{Z}$ is invertible: two factorizations then differ by $\mathbf{Q} \mapsto \mathbf{QD}$ and $\mathbf{R} \mapsto \mathbf{D}^*\mathbf{R}$ with $\mathbf{D}$ unitary diagonal, and $(\mathbf{D}^*\mathbf{R})(\mathbf{QD}) = \mathbf{D}^*(\mathbf{RQ})\mathbf{D}$ has exactly the same pattern of zeros as $\mathbf{RQ}$. Invertibility is doing work there: for $\mathbf{Z} = \mathbf{e}_1\mathbf{e}_3^\top \in M_3(\mathbb{R})$, which is upper Hessenberg and singular, the reversal permutation $\mathbf{Q}$ (with $\mathbf{Qe}_j = \mathbf{e}_{4-j}$) and $\mathbf{R} = \mathbf{e}_3\mathbf{e}_3^\top$ give an orthogonal $\mathbf{Q}$, an upper triangular $\mathbf{R}$ and $\mathbf{QR} = \mathbf{Z}$, while $\mathbf{RQ} = \mathbf{e}_3\mathbf{e}_1^\top$ has a non-zero $(3,1)$ entry and is not upper Hessenberg.

Quick check. A symmetric matrix is upper Hessenberg exactly when it is tridiagonal. What does Proposition 23.5.4 then say about a QR step applied to a symmetric tridiagonal matrix?

Solution. That the step returns a symmetric tridiagonal matrix. Symmetry survives because $\mathbf{RQ} = \mathbf{Q}^\top\mathbf{ZQ}$ is a congruence by an orthogonal matrix as well as a similarity, so $(\mathbf{Q}^\top\mathbf{ZQ})^\top = \mathbf{Q}^\top\mathbf{Z}^\top\mathbf{Q} = \mathbf{Q}^\top\mathbf{ZQ}$; and Hessenberg form survives by the proposition. A symmetric Hessenberg matrix has $z_{ij} = 0$ whenever $i > j+1$, hence also whenever $j > i+1$, which is tridiagonality. The cost then drops further, to $O(n)$ per step.

23.5.5 Shifts

The rate $|\lambda_{i+1}/\lambda_i|$ is a property of $\mathbf{A}$, and we cannot change $\mathbf{A}$. We can change the matrix we iterate on. For any $\mu \in F$, the matrix $\mathbf{A} - \mu\mathbf{I}$ has eigenvalues $\lambda_i - \mu$, so its ratios of moduli are $|\lambda_{i+1} - \mu|/|\lambda_i - \mu|$ — and a μ close to λ_n makes the last of these tiny. This is the same observation that turned the power method into inverse iteration in Section 4, where the shift μ was used to make $(\mathbf{A} - \mu\mathbf{I})^{-1}$ have a huge dominant eigenvalue (Theorem 23.4.3).

The **shifted QR step** is

$$\mathbf{A}^{(k)} - \mu_k\mathbf{I} = \mathbf{Q}^{(k)}\mathbf{R}^{(k)}, \qquad \mathbf{A}^{(k+1)} = \mathbf{R}^{(k)}\mathbf{Q}^{(k)} + \mu_k\mathbf{I},$$

and it is still a unitary similarity: $\mathbf{R}^{(k)}\mathbf{Q}^{(k)} = (\mathbf{Q}^{(k)})^*(\mathbf{A}^{(k)} - \mu_k\mathbf{I})\mathbf{Q}^{(k)}$, so adding $\mu_k\mathbf{I}$ back gives $\mathbf{A}^{(k+1)} = (\mathbf{Q}^{(k)})^*\mathbf{A}^{(k)}\mathbf{Q}^{(k)}$ exactly as in Proposition 23.5.1. The shift may be changed at every step, which is why the ratio can be driven down as the information improves. And since $\mathbf{A}^{(k)} - \mu_k\mathbf{I}$ is Hessenberg whenever $\mathbf{A}^{(k)}$ is, Proposition 23.5.4 applies to the shifted step: as it stands for a real μ_k, and in the complex form recorded in the Remark after it for a μ_k off the real line, which the second of the two shifts below produces.

Two shifts are standard. The **Rayleigh shift** takes $\mu_k = a_{nn}^{(k)}$, the trailing diagonal entry; when $\mathbf{A}$ is Hermitian this is the Rayleigh quotient $R_{\mathbf{A}^{(k)}}(\mathbf{e}_n)$ of Definition 16.1.1, hence a good

eigenvalue estimate as soon as $\mathbf{e}_n$ is nearly an eigenvector. The **Wilkinson shift** takes μ_k to be the eigenvalue of the trailing 2×2 block of $\mathbf{A}^{(k)}$ nearer to $a_{nn}^{(k)}$; it costs one quadratic formula and, unlike the Rayleigh shift, it can leave the real line, which is what lets it break the deadlock of a rotation.

The extreme case says exactly why shifting works.

Proposition 23.5.5 — An Exact Shift Deflates in One Step

Let $\mathbf{Z} \in M_n(F)$ be upper Hessenberg, $n \geq 2$, with all its subdiagonal entries $z_{i+1,i}$ **non-zero** — such a matrix is called **unreduced**, the word Lemma 16.4.5 used for the tridiagonal case. Let $\mu \in F$ be an eigenvalue of $\mathbf{Z}$. Let $\mathbf{Z} - \mu\mathbf{I} = \mathbf{QR}$ with $\mathbf{Q}$ unitary and $\mathbf{R}$ upper triangular, and put $\mathbf{Z}' = \mathbf{RQ} + \mu\mathbf{I}$. Then the last row of $\mathbf{R}$ is zero, and the last row of $\mathbf{Z}'$ is $\mu\,\mathbf{e}_n^\top$. In particular $z'_{n,n-1} = 0$ and $z'_{nn} = \mu$.

Idea. An unreduced Hessenberg matrix cannot lose more than one dimension of rank: its first $n-1$ columns are independent whatever the matrix does, because the subdiagonal alone makes them so. Shifting by an eigenvalue makes the matrix singular, so the one missing dimension must be the last one, and in a QR factorization "the last dimension is missing" reads as a zero last row of $\mathbf{R}$.

Proof. Write $\mathbf{B} = \mathbf{Z} - \mu\mathbf{I}$, again upper Hessenberg with the same non-zero subdiagonal entries.

First, the columns $\mathbf{b}_1, \dots, \mathbf{b}_{n-1}$ of $\mathbf{B}$ are linearly independent. Delete the first row: what remains is the $(n-1) \times (n-1)$ matrix with entries $b_{i+1,j}$ for $1 \leq i, j \leq n-1$, which is **lower** triangular, since $b_{i+1,j} = 0$ for $i+1 > j+1$, that is for $i > j$; and its diagonal entries $b_{j+1,j}$ are non-zero. A triangular matrix with non-zero diagonal is invertible (Lemma 2.6.2), so those $n-1$ truncated columns are independent, and the full columns are independent a fortiori.

Second, $\operatorname{rank}\mathbf{B} = n-1$: it is at least $n-1$ by the previous paragraph and at most $n-1$ because $\mathbf{B}$ is singular, μ being an eigenvalue of $\mathbf{Z}$.

Now $\mathbf{B} = \mathbf{QR}$ with $\mathbf{Q}$ invertible, so $\operatorname{rank}\mathbf{R} = \operatorname{rank}\mathbf{B} = n-1$ and the columns $\mathbf{Re}_1, \dots, \mathbf{Re}_{n-1}$ are independent, being $\mathbf{Q}^*\mathbf{b}_1, \dots, \mathbf{Q}^*\mathbf{b}_{n-1}$. Since $\mathbf{R}$ is upper triangular, its last row has the single possibly non-zero entry r_{nn}; if $r_{nn} \neq 0$, then $\mathbf{R}$ would be invertible (Lemma 2.6.2 applied after noting that independence of the first $n-1$ columns forces $r_{11}, \dots, r_{n-1,n-1} \neq 0$), contradicting $\operatorname{rank}\mathbf{R} = n-1$. Hence $r_{nn} = 0$ and the last row of $\mathbf{R}$ is zero.

A matrix with zero last row keeps it under multiplication on the right: $(\mathbf{RQ})_{nj} = \sum_k r_{nk} q_{kj} = 0$. So the last row of $\mathbf{RQ}$ is zero and the last row of $\mathbf{Z}' = \mathbf{RQ} + \mu\mathbf{I}$ is $\mu\,\mathbf{e}_n^\top$, as claimed.

■

The proposition is the ideal case, and it explains the practice: the closer μ_k is to an eigenvalue, the smaller $z'_{n,n-1}$ is observed to become, and the algorithm watches that one entry. When it falls below a tolerance it is set to zero, the matrix splits into a smaller Hessenberg block and a known eigenvalue, and the iteration restarts on the block. This is **deflation**, and with it the algorithm is observed to finish after $O(n)$ steps in total rather than converging forever.

Two claims in that paragraph are descriptions of observed behavior, not theorems, and this book proves neither: that a nearer shift always gives a smaller subdiagonal entry, and that the shifted algorithm terminates after $O(n)$ steps. Nothing in this section or later depends on them. What is proved is the exact case, Proposition 23.5.5, and the example below exhibits it.

Example. (The shift repairs the rotation, and deflates a symmetric example)

(a) Apply one shifted QR step with $\mu = i$ to $\mathbf{B} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$.

(b) Apply one shifted QR step with $\mu = 2$ to the symmetric tridiagonal matrix $\mathbf{A}$ with diagonal $(2, 2, 2)$ and off-diagonal entries 1.

Solution.

(a) Here $\mu = i$ is an eigenvalue, so Proposition 23.5.5 predicts an exact deflation. Indeed

$$\mathbf{B} - i\mathbf{I} = \begin{pmatrix} -i & -1 \\ 1 & -i \end{pmatrix},$$

whose second column is $-i$ times the first, so the matrix has rank 1. Its first column has norm $\sqrt{2}$, so take $\mathbf{q}_1 = \frac{1}{\sqrt{2}}(-i, 1)$ and $\mathbf{q}_2 = \frac{1}{\sqrt{2}}(1, -i)$, which is a unit vector orthogonal to $\mathbf{q}_1$ since $\overline{(-i)} \cdot 1 + \overline{1} \cdot (-i) = i - i = 0$. With $\mathbf{Q} = (\mathbf{q}_1 \mid \mathbf{q}_2)$ one computes $\mathbf{R} = \mathbf{Q}^*(\mathbf{B} - i\mathbf{I})$, which is

$$\mathbf{R} = \begin{pmatrix} \sqrt{2} & -i\sqrt{2} \\ 0 & 0 \end{pmatrix},$$

with zero last row as predicted. Then $\mathbf{RQ} = \operatorname{diag}(-2i, 0)$, and

$$\mathbf{B}' = \mathbf{RQ} + i\mathbf{I} = \operatorname{diag}(-i,\, i).$$

One step, and the eigenvalues are on the diagonal. The unshifted iteration would have run forever.

(b) The matrix is

$$\mathbf{A} = \begin{pmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{pmatrix}, \qquad \mathbf{A} - 2\mathbf{I} = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix},$$

and 2 is an eigenvalue of $\mathbf{A}$, since $(\mathbf{A} - 2\mathbf{I})(1, 0, -1) = \mathbf{0}$. Two Givens rotations triangularize $\mathbf{A} - 2\mathbf{I}$, as in the proof of Proposition 23.5.4. The first uses the entries 0 and 1 in positions $(1, 1)$ and $(2, 1)$, so $r = 1$, $c_1 = 0$, $s_1 = 1$, and $\mathbf{G}_1$ exchanges rows 1 and 2 with a sign, producing rows $(1, 0, 1)$, $(0, -1, 0)$, $(0, 1, 0)$. The second uses the entries -1 and 1 now in positions $(2, 2)$ and $(3, 2)$, so $r = \sqrt{2}$, $c_2 = -1/\sqrt{2}$, $s_2 = 1/\sqrt{2}$, and it turns those two rows into $(0, \sqrt{2}, 0)$ and $\mathbf{0}$. Hence

$$\mathbf{R} = \begin{pmatrix} 1 & 0 & 1 \\ 0 & \sqrt{2} & 0 \\ 0 & 0 & 0 \end{pmatrix}, \qquad \mathbf{Q} = \mathbf{G}_1^{\top}\mathbf{G}_2^{\top} = \begin{pmatrix} 0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ 1 & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \end{pmatrix},$$

with the last row of $\mathbf{R}$ zero, as Proposition 23.5.5 predicts. One checks $\mathbf{QR} = \mathbf{A} - 2\mathbf{I}$ column by column. Multiplying back and restoring the shift,

$$\mathbf{A}' = \mathbf{RQ} + 2\mathbf{I} = \begin{pmatrix} 2 & \sqrt{2} & 0 \\ \sqrt{2} & 2 & 0 \\ 0 & 0 & 2 \end{pmatrix}.$$

The last row and column have split off, carrying the eigenvalue 2, and the remaining 2×2 block has eigenvalues $2 \pm \sqrt{2}$ — the other two eigenvalues of $\mathbf{A}$. One shifted step, and the problem is finished.

23.5.6 Three unshifted steps, watched

Example. (The subdiagonal shrinking at the predicted rate)

Run the unshifted QR iteration on the symmetric tridiagonal matrix

$$\mathbf{A} = \begin{pmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{pmatrix},$$

whose eigenvalues are $2 + \sqrt{2}$, 2 and $2 - \sqrt{2}$. Carry out the first step exactly, and tabulate three steps.

Solution. Step one, by hand. Apply Theorem 10.2.2 to the columns $\mathbf{a}_1 = (2, 1, 0)$, $\mathbf{a}_2 = (1, 2, 1)$, $\mathbf{a}_3 = (0, 1, 2)$.

From $\mathbf{a}_1$: $r_{11} = \|\mathbf{a}_1\| = \sqrt{5}$ and $\mathbf{q}_1 = \frac{1}{\sqrt{5}}(2, 1, 0)$.

From $\mathbf{a}_2$: $r_{12} = \langle \mathbf{a}_2, \mathbf{q}_1 \rangle = 4/\sqrt{5}$, and

$$\mathbf{w}_2 = \mathbf{a}_2 - \tfrac{4}{5}(2, 1, 0) = \tfrac{1}{5}(-3, 6, 5), \qquad r_{22} = \|\mathbf{w}_2\| = \sqrt{14/5},$$

since $9 + 36 + 25 = 70$ and $\sqrt{70}/5 = \sqrt{14/5}$; so $\mathbf{q}_2 = \frac{1}{\sqrt{70}}(-3, 6, 5)$.

From $\mathbf{a}_3$: $r_{13} = 1/\sqrt{5}$ and $r_{23} = 16/\sqrt{70}$, and

$$\mathbf{w}_3 = \mathbf{a}_3 - \tfrac{1}{5}(2, 1, 0) - \tfrac{16}{70}(-3, 6, 5) = \tfrac{2}{7}(1, -2, 3), \qquad r_{33} = \tfrac{2\sqrt{14}}{7},$$

so $\mathbf{q}_3 = \frac{1}{\sqrt{14}}(1, -2, 3)$. Now $\mathbf{A}^{(2)} = \mathbf{RQ}$. Its $(1,1)$ entry is the first row of $\mathbf{R}$ against the first column of $\mathbf{Q}$, namely

$$\sqrt{5} \cdot \tfrac{2}{\sqrt{5}} + \tfrac{4}{\sqrt{5}} \cdot \tfrac{1}{\sqrt{5}} + \tfrac{1}{\sqrt{5}} \cdot 0 = 2 + \tfrac{4}{5} = \tfrac{14}{5},$$

and its $(2,1)$ entry is $\sqrt{14/5} \cdot \frac{1}{\sqrt{5}} + \frac{16}{\sqrt{70}} \cdot 0 = \sqrt{14}/5$. Continuing,

$$\mathbf{A}^{(2)} = \begin{pmatrix} \frac{14}{5} & \frac{\sqrt{14}}{5} & 0 \\ \frac{\sqrt{14}}{5} & \frac{82}{35} & \frac{2\sqrt{5}}{7} \\ 0 & \frac{2\sqrt{5}}{7} & \frac{6}{7} \end{pmatrix}.$$

Three checks: the matrix is symmetric and tridiagonal, as the Quick check after Proposition 23.5.4 predicted; its trace is $\frac{14}{5} + \frac{82}{35} + \frac{6}{7} = \frac{98+82+30}{35} = 6 = \operatorname{tr} \mathbf{A}$; and the entry $(3,1)$ is zero, not merely small.

Three steps, to eight places. The diagonal entries and the two subdiagonal entries run as follows.

k	$a_{11}^{(k)}$	$a_{22}^{(k)}$	$a_{33}^{(k)}$	$\lvert a_{21}^{(k)} \rvert$	$\lvert a_{32}^{(k)} \rvert$
1	2.00000000	2.00000000	2.00000000	1.000000	1.000000
2	2.80000000	2.34285714	0.85714286	0.748331	0.638877
3	3.14285714	2.24844720	0.60869565	0.559397	0.187848
4	3.30841121	2.10394692	0.58764187	0.372193	0.052177

The three diagonal entries are heading for $2 + \sqrt{2} = 3.41421356$, 2 and $2 - \sqrt{2} = 0.58578644$, largest modulus first — the order the convergence theorem quoted above predicts, exhibited here rather than proved. The two subdiagonal entries shrink by factors

$$0.748,\ 0.748,\ 0.665, \ldots \qquad \text{and} \qquad 0.639,\ 0.294,\ 0.278, \ldots$$

The predicted asymptotic factors are $|\lambda_2/\lambda_1| = 2/(2+\sqrt{2}) = 0.585786$ and $|\lambda_3/\lambda_2| = (2-\sqrt{2})/2 = 0.292893$. The second entry has already settled onto its rate; the first is still approaching it, and by step 10 its factor is 0.5859. Convergence is linear, and slow: each step buys about a quarter of a decimal digit in the $(2,1)$ entry. That is the cost of not shifting.

23.5.7 Exercises

23.5.7.1 A. Check your understanding

Exercise A1.

(a) Write down one step of the unshifted QR iteration, and one step of the shifted one, and prove in one line each that both are similarities.

(b) State Theorem 23.5.2, and say in one sentence what it has to do with the power method.

(c) True or false: the QR iterates of a matrix always converge to an upper triangular matrix. Justify your answer.

(d) Why is the iteration run on an upper Hessenberg matrix rather than on a full one? Give the two costs.

(e) In Proposition 23.5.5, which hypothesis on $\mathbf{Z}$ is doing the work, and where exactly is it used?

Solution.

(a) Unshifted: $\mathbf{A}^{(k)} = \mathbf{QR}$, $\mathbf{A}^{(k+1)} = \mathbf{RQ}$; then $\mathbf{RQ} = \mathbf{Q}^*\mathbf{QRQ} = \mathbf{Q}^*\mathbf{A}^{(k)}\mathbf{Q}$. Shifted: $\mathbf{A}^{(k)} - \mu\mathbf{I} = \mathbf{QR}$, $\mathbf{A}^{(k+1)} = \mathbf{RQ} + \mu\mathbf{I}$; then $\mathbf{RQ} + \mu\mathbf{I} = \mathbf{Q}^*(\mathbf{A}^{(k)} - \mu\mathbf{I})\mathbf{Q} + \mu\mathbf{Q}^*\mathbf{Q} = \mathbf{Q}^*\mathbf{A}^{(k)}\mathbf{Q}$.

(b) It says $\mathbf{A}^k = \mathbf{U}_k\mathbf{T}_k$ with $\mathbf{U}_k = \mathbf{Q}^{(1)}\cdots\mathbf{Q}^{(k)}$ unitary and $\mathbf{T}_k = \mathbf{R}^{(k)}\cdots\mathbf{R}^{(1)}$ upper

triangular, and that $\mathbf{A}^{(k+1)} = \mathbf{U}_k^* \mathbf{A} \mathbf{U}_k$. Comparing first columns, the first column of $\mathbf{U}_k$ is $\mathbf{A}^k \mathbf{e}_1$ normalized, which is the k-th power-method iterate started at $\mathbf{e}_1$.

(c) False. The rotation $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ is a fixed point of the unshifted iteration (Example (Two matrices the iteration cannot move)) and is not triangular; its two eigenvalues have the same modulus, which is exactly the hypothesis Theorem 23.5.3 needs.

(d) Because a QR step on a full matrix costs $O(n^3)$ flops, with the count genuinely growing like n^3, while a step on a Hessenberg matrix costs about $6n^2$ (Proposition 23.5.4), and the pattern is preserved, so the saving is repeated at every step. The reduction itself is $O(n^3)$, paid once (Theorem 10.8.5).

(e) That every subdiagonal entry of $\mathbf{Z}$ is non-zero. It is used exactly once, to show that the first $n-1$ columns of $\mathbf{Z} - \mu\mathbf{I}$ are independent: deleting the first row leaves a lower triangular matrix whose diagonal is that subdiagonal. Without it $\mathbf{Z} - \mu\mathbf{I}$ could drop rank in an earlier column, and the zero row of $\mathbf{R}$ need not be the last.

23.5.7.2 B. Practice

Exercise B1: One step by hand.

Let $\mathbf{A} = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$. Compute the QR factorization of $\mathbf{A}$ in the sense of Theorem 10.8.1, then $\mathbf{A}^{(2)} = \mathbf{RQ}$. Verify that $\mathbf{A}^{(2)}$ is symmetric, has trace 4 and determinant 3, and that its off-diagonal entry is smaller than that of $\mathbf{A}$. Hence estimate how many steps are needed to make the off-diagonal entry smaller than 10^{-3}.

Solution. The columns are $\mathbf{a}_1 = (2,1)$ and $\mathbf{a}_2 = (1,2)$. Then $r_{11} = \sqrt{5}$, $\mathbf{q}_1 = \frac{1}{\sqrt{5}}(2,1)$, $r_{12} = \langle \mathbf{a}_2, \mathbf{q}_1 \rangle = 4/\sqrt{5}$, and

$$\mathbf{w}_2 = (1,2) - \tfrac{4}{5}(2,1) = \tfrac{3}{5}(-1,2), \qquad r_{22} = \tfrac{3}{\sqrt{5}}, \qquad \mathbf{q}_2 = \tfrac{1}{\sqrt{5}}(-1,2).$$

So

$$\mathbf{Q} = \tfrac{1}{\sqrt{5}} \begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix}, \qquad \mathbf{R} = \tfrac{1}{\sqrt{5}} \begin{pmatrix} 5 & 4 \\ 0 & 3 \end{pmatrix},$$

and

$$\mathbf{A}^{(2)} = \mathbf{RQ} = \tfrac{1}{5} \begin{pmatrix} 5 & 4 \\ 0 & 3 \end{pmatrix} \begin{pmatrix} 2 & -1 \\ 1 & 2 \end{pmatrix} = \tfrac{1}{5} \begin{pmatrix} 14 & 3 \\ 3 & 6 \end{pmatrix}.$$

It is symmetric; its trace is $20/5 = 4 = \operatorname{tr} \mathbf{A}$; its determinant is $(84-9)/25 = 3 = \det \mathbf{A}$. The off-diagonal entry fell from 1 to $3/5$.

The eigenvalues are 3 and 1, so Theorem 23.5.3 gives the asymptotic factor $t = 1/3$ per step. To take $3/5$ below 10^{-3} needs $(1/3)^m \le 10^{-3}/(3/5)$, that is $m \ge \log(600)/\log 3 \approx 5.8$: about six further steps, so seven in all. (The first steps are a little slower than the asymptotic rate, so eight is a safer count.)

Exercise B2: Fixed points.

Determine which of the following matrices are fixed points of the unshifted QR iteration, that is, satisfy $\mathbf{A}^{(2)} = \mathbf{A}^{(1)}$. Justify your answer; for those that are not, name what changes.

(a) any upper triangular $\mathbf{A}$ with positive real diagonal entries;
(b) any unitary $\mathbf{A}$;
(c) $\mathbf{A} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$;
(d) any normal $\mathbf{A}$.

Solution.

(a) Yes. Then $\mathbf{A} = \mathbf{IA}$ is a factorization with $\mathbf{I}$ unitary and $\mathbf{A}$ upper triangular with positive diagonal, hence the unique one (Theorem 10.8.1), and $\mathbf{A}^{(2)} = \mathbf{AI} = \mathbf{A}$.
(b) Yes. Then $\mathbf{A} = \mathbf{AI}$ is a factorization with $\mathbf{A}$ unitary and $\mathbf{I}$ upper triangular with positive diagonal, hence the unique one, and $\mathbf{A}^{(2)} = \mathbf{IA} = \mathbf{A}$.
(c) Yes, by (b): the matrix is a permutation matrix, so its columns are orthonormal. This is worth noticing because its eigenvalues are 1 and -1, of equal modulus — another instance of the obstruction of Example (The unshifted algorithm on a rotation), and this one is symmetric, so unlike the rotation it *is* orthogonally similar to a diagonal matrix. The unshifted iteration simply will not find it.
(d) No. A normal matrix need not be fixed: $\mathbf{A} = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$ is symmetric, hence normal, and Exercise (B1: One step by hand) computed $\mathbf{A}^{(2)} = \frac{1}{5}\begin{pmatrix} 14 & 3 \\ 3 & 6 \end{pmatrix} \neq \mathbf{A}$. What is preserved is normality, not the matrix: $\mathbf{A}^{(2)} = \mathbf{Q}^*\mathbf{AQ}$ is unitarily similar to $\mathbf{A}$, and normality is invariant under unitary similarity.

Exercise B3: A shift that deflates.

Let $\mathbf{Z} = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$. Take μ to be either eigenvalue of $\mathbf{Z}$ and carry out one shifted QR step. Verify the conclusion of Proposition 23.5.5. *Hint: you need only the last row of* $\mathbf{R}$.

Solution. The characteristic polynomial is $x^2 - 5x - 2$, with roots $\mu_\pm = (5 \pm \sqrt{33})/2$. Every 2×2 matrix is upper Hessenberg, and the single subdiagonal entry 3 is non-zero, so Proposition 23.5.5 applies with $n = 2$. Take $\mu = \mu_+$. Then

$$\mathbf{Z} - \mu\mathbf{I} = \begin{pmatrix} 1-\mu & 2 \\ 3 & 4-\mu \end{pmatrix}$$

is singular, of rank 1 since it is non-zero. Its first column has norm $r = \sqrt{(1-\mu)^2 + 9} \neq 0$, so a QR factorization has $\mathbf{q}_1 = \frac{1}{r}(1-\mu, 3)$ and $r_{11} = r \neq 0$. Because the rank is 1, the second column of $\mathbf{R}$ is a multiple of $\mathbf{e}_1$, so $r_{22} = 0$ and the last row of $\mathbf{R}$ vanishes. Then the last row of $\mathbf{RQ}$ vanishes too, and $\mathbf{Z}' = \mathbf{RQ} + \mu\mathbf{I}$ has last row $(0, \mu)$. Its $(1,1)$ entry is then $\operatorname{tr}\mathbf{Z} - \mu = 5 - \mu = \mu_-$, since the trace is preserved. One step produced both eigenvalues exactly.

23.5.7.3 C. Going deeper

Exercise C1: Hessenberg form is not enough by itself.

(a) Prove that if $\mathbf{Z}$ is upper Hessenberg with $z_{m+1,m} = 0$ for some $1 \le m \le n-1$, then $\operatorname{spec}(\mathbf{Z}) = \operatorname{spec}(\mathbf{Z}_{11}) \cup \operatorname{spec}(\mathbf{Z}_{22})$, where $\mathbf{Z}_{11}$ is the leading $m \times m$ block and $\mathbf{Z}_{22}$ the trailing $(n-m) \times (n-m)$ block.

(b) Deduce that a QR implementation may, at every step, replace the problem by two smaller ones as soon as one subdiagonal entry vanishes.

(c) Give a 3×3 upper Hessenberg matrix with no zero subdiagonal entry for which the unshifted iteration never reduces any subdiagonal entry at all.

Solution.

(a) With $z_{m+1,m} = 0$ and $\mathbf{Z}$ upper Hessenberg, every entry z_{ij} with $i > m \ge j$ vanishes: for $i > m+1$ this is $i > j+1$, and for $i = m+1$ it is either $j < m$, again $i > j+1$, or $j = m$, the assumed entry. So $\mathbf{Z}$ is block upper triangular with diagonal blocks $\mathbf{Z}_{11}$ and $\mathbf{Z}_{22}$. By Theorem 7.1.1 and the determinant of a block triangular matrix (Theorem 6.8.4), $p_{\mathbf{Z}}(x) = p_{\mathbf{Z}_{11}}(x)\, p_{\mathbf{Z}_{22}}(x)$, so the eigenvalues of $\mathbf{Z}$ are those of the two blocks together.

(b) The two blocks are again upper Hessenberg, and by (a) computing their spectra computes that of $\mathbf{Z}$. Each step on a block of size m costs about $6m^2$ rather than $6n^2$ (Proposition 23.5.4), so splitting is a strict gain; and part (a) guarantees no eigenvalue is lost. This is deflation.

(c) Take the cyclic permutation matrix

$$\mathbf{Z} = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix},$$

which is upper Hessenberg with subdiagonal entries $1, 1$, and is orthogonal. By Exercise (B2: Fixed points) (b) it is a fixed point of the unshifted iteration, so no subdiagonal entry ever moves. Its eigenvalues are the three cube roots of 1, all of modulus 1 — the obstruction of Theorem 23.5.3 in its purest form.

Exercise C2: Hermitian iterates and the Rayleigh quotient.

Let $\mathbf{A} \in M_n(\mathbb{C})$ be Hermitian and let $\mathbf{A}^{(k)}$ be its unshifted QR iterates.

(a) Prove that every $\mathbf{A}^{(k)}$ is Hermitian with the same eigenvalues as $\mathbf{A}$.

(b) Prove that $a_{nn}^{(k)} = R_{\mathbf{A}}(\mathbf{u}_n^{(k)})$, where $\mathbf{u}_n^{(k)}$ is the last column of $\mathbf{U}_{k-1}$ and $R_{\mathbf{A}}$ is the Rayleigh quotient of Definition 16.1.1.

(c) Hence explain, citing Theorem 19.6.1, why the Rayleigh shift $\mu_k = a_{nn}^{(k)}$ is a certified eigenvalue estimate, and say what the certificate is.

Solution.

(a) By Theorem 23.5.2, $\mathbf{A}^{(k)} = \mathbf{U}_{k-1}^{*}\mathbf{A}\mathbf{U}_{k-1}$, with $\mathbf{U}_0 = \mathbf{I}$ at $k = 1$, so $(\mathbf{A}^{(k)})^{*} = \mathbf{U}_{k-1}^{*}\mathbf{A}^{*}\mathbf{U}_{k-1} = \mathbf{A}^{(k)}$, and unitary similarity preserves eigenvalues.

(b) Writing $\mathbf{u}_n = \mathbf{U}_{k-1}\mathbf{e}_n$, which is a unit vector since $\mathbf{U}_{k-1}$ is unitary,

$$a_{nn}^{(k)} = \mathbf{e}_n^* \mathbf{A}^{(k)} \mathbf{e}_n = \mathbf{e}_n^* \mathbf{U}_{k-1}^* \mathbf{A} \mathbf{U}_{k-1} \mathbf{e}_n = \mathbf{u}_n^* \mathbf{A} \mathbf{u}_n = R_{\mathbf{A}}(\mathbf{u}_n),$$

the last equality because $R_{\mathbf{A}}(\mathbf{x}) = \mathbf{x}^*\mathbf{A}\mathbf{x}/\mathbf{x}^*\mathbf{x}$ and $\mathbf{u}_n^*\mathbf{u}_n = 1$.

(c) Put $\mu = a_{nn}^{(k)}$ and $\mathbf{r} = \mathbf{A}\mathbf{u}_n - \mu\mathbf{u}_n$. Then μ is real, $\mathbf{A}$ being Hermitian, and Theorem 19.6.1 says that $\mathbf{A}$ has an eigenvalue in $[\mu - \|\mathbf{r}\|_2, \mu + \|\mathbf{r}\|_2]$. The certificate is $\|\mathbf{r}\|_2$, and it costs nothing extra: by the computation in (b), $\mathbf{U}_{k-1}^*\mathbf{r} = \mathbf{A}^{(k)}\mathbf{e}_n - \mu\mathbf{e}_n$ is the last column of $\mathbf{A}^{(k)}$ with its diagonal entry removed, so $\|\mathbf{r}\|_2$ is the Euclidean norm of the entries of that column other than the diagonal one. If $\mathbf{A}$ was first reduced to Hessenberg form, so that every $\mathbf{A}^{(k)}$ is Hermitian and upper Hessenberg, hence tridiagonal, that norm is the single entry $|a_{n-1,n}^{(k)}|$. The algorithm is already watching that number.

Exercise C3: Why the powers are the right object.

Let $\mathbf{A} \in M_n(\mathbb{C})$ be invertible, with unshifted QR iterates as in Definition 23.5.1.

(a) Prove that for $1 \le j \le n$, the subspace spanned by the first j columns of $\mathbf{U}_k$ equals $\mathbf{A}^k(\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_j))$.

(b) Deduce that if the first j columns of $\mathbf{U}_k$ converge to a basis of an $\mathbf{A}$-invariant subspace W, then the entries of $\mathbf{A}^{(k+1)}$ in rows $j+1, \dots, n$ of columns $1, \dots, j$ tend to 0.

Hint for (b): write the entries as inner products of $\mathbf{A}$ *applied to one column against another.*

Solution.

(a) By Theorem 23.5.2, $\mathbf{A}^k = \mathbf{U}_k\mathbf{T}_k$ with $\mathbf{T}_k$ upper triangular and invertible (Quick check above), so $\mathbf{A}^k\mathbf{e}_i = \mathbf{U}_k\mathbf{T}_k\mathbf{e}_i$ lies in $\operatorname{span}(\mathbf{U}_k\mathbf{e}_1, \dots, \mathbf{U}_k\mathbf{e}_i)$ for each i, since $\mathbf{T}_k\mathbf{e}_i$ has zeros below row i. Hence $\mathbf{A}^k(\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_j)) \subseteq \operatorname{span}(\mathbf{U}_k\mathbf{e}_1, \dots, \mathbf{U}_k\mathbf{e}_j)$. Both sides have dimension j: the left because $\mathbf{A}^k$ is invertible, the right because the columns of a unitary matrix are independent. One inclusion plus equal dimension gives equality.

(b) Write $\mathbf{u}_i = \mathbf{U}_k\mathbf{e}_i$. For $p > j \ge q$,

$$a_{pq}^{(k+1)} = \mathbf{e}_p^*\mathbf{U}_k^*\mathbf{A}\mathbf{U}_k\mathbf{e}_q = \mathbf{u}_p^*\mathbf{A}\mathbf{u}_q = \langle \mathbf{A}\mathbf{u}_q, \mathbf{u}_p \rangle.$$

Suppose $\mathbf{u}_1, \dots, \mathbf{u}_j$ converge to an orthonormal basis $\mathbf{w}_1, \dots, \mathbf{w}_j$ of an $\mathbf{A}$-invariant subspace W, let P be the orthogonal projection onto W (Definition 10.3.2) and put $\delta_k = \max_{q \le j} \|\mathbf{u}_q - \mathbf{w}_q\|_2$, so $\delta_k \to 0$. Since $\mathbf{A}\mathbf{w}_q \in W$, we have $(\mathbf{I} - P)\mathbf{A}\mathbf{w}_q = \mathbf{0}$ and hence $\|(\mathbf{I} - P)\mathbf{A}\mathbf{u}_q\|_2 = \|(\mathbf{I} - P)\mathbf{A}(\mathbf{u}_q - \mathbf{w}_q)\|_2 \le \|\mathbf{A}\|_2\delta_k$. Since $\langle \mathbf{u}_p, \mathbf{u}_q \rangle = 0$ for $q \le j < p$, we have $|\langle \mathbf{u}_p, \mathbf{w}_q \rangle| = |\langle \mathbf{u}_p, \mathbf{w}_q - \mathbf{u}_q \rangle| \le \delta_k$ by Cauchy–Schwarz (Theorem 10.1.5), so $\|P\mathbf{u}_p\|_2 \le j\,\delta_k$. Splitting $\mathbf{u}_p$ and using that P is self-adjoint,

$$\begin{aligned} |\langle \mathbf{A}\mathbf{u}_q, \mathbf{u}_p \rangle| &= \big|\langle (\mathbf{I} - P)\mathbf{A}\mathbf{u}_q, \mathbf{u}_p \rangle + \langle \mathbf{A}\mathbf{u}_q, P\mathbf{u}_p \rangle\big| \\ &\le \|(\mathbf{I} - P)\mathbf{A}\mathbf{u}_q\|_2 + \|\mathbf{A}\|_2\|P\mathbf{u}_p\|_2 \;\le\; (1 + j)\|\mathbf{A}\|_2\,\delta_k, \end{aligned}$$

by Cauchy–Schwarz again and $\|\mathbf{u}_p\|_2 = \|\mathbf{u}_q\|_2 = 1$. The right-hand side tends to

> 0, so $a_{pq}^{(k+1)} \to 0$. This is Theorem 23.5.3 for $j = 1$, read as a statement about invariant subspaces rather than about eigenvectors, and it is the form in which the general convergence theorem quoted above is proved.

23.6 Krylov Subspaces

Sections 4 and 5 both consist of multiplying by $\mathbf{A}$ over and over: the power method forms $\mathbf{b}, \mathbf{Ab}, \mathbf{A}^2\mathbf{b}, \dots$ and keeps only the newest vector, and the QR algorithm, by Theorem 23.5.2, does the same thing to $\mathbf{e}_1$ inside its first column. In both cases everything computed before the last step is thrown away, and this section keeps it instead. The span of the vectors produced by k matrix-vector products is a subspace of dimension up to k, and the best approximations it contains are far better than its last vector alone. That subspace, the process that builds an orthonormal basis of it, and the eigenvalue estimates it yields are the subject here.

Throughout, $F = \mathbb{R}$ or $F = \mathbb{C}$, and F^n carries the standard inner product, linear in the first slot, with $\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{y}^*\mathbf{x}$ and $\|\cdot\| = \|\cdot\|_2$.

23.6.1 The space that k products span

A large matrix is often not available as a table of n^2 numbers at all. What is available is a rule for computing $\mathbf{Ax}$ from $\mathbf{x}$ — a sparse pattern of neighbors on a grid, a graph, a differential operator discretized. For such a matrix, forming $\mathbf{Ax}$ is cheap and forming $\mathbf{A}^{-1}$, or even looking at an entry of $\mathbf{A}^2$, is not. So the honest question is: after k multiplications, what do we possess?

We possess $\mathbf{b}, \mathbf{Ab}, \dots, \mathbf{A}^{k-1}\mathbf{b}$, and hence every linear combination of them. The power method uses one of these vectors. That is wasteful, and the waste has a name only because the span deserves one.

The Krylov space is everything that k matrix-vector products can reach.

Definition 23.6.1 — Krylov Subspace

Let $\mathbf{A} \in M_n(F)$, let $\mathbf{b} \in F^n$ and let $k \geq 1$ be an integer. The **k-th Krylov subspace** of the pair $(\mathbf{A}, \mathbf{b})$ is

$$\mathcal{K}_k(\mathbf{A}, \mathbf{b}) \coloneqq \operatorname{span}\big(\mathbf{b},\ \mathbf{Ab},\ \mathbf{A}^2\mathbf{b},\ \dots,\ \mathbf{A}^{k-1}\mathbf{b}\big) \subseteq F^n.$$

In words: we list the first k vectors of the sequence obtained by repeatedly applying $\mathbf{A}$ to $\mathbf{b}$ — **starting at $\mathbf{b}$ itself**, so that the last one is $\mathbf{A}^{k-1}\mathbf{b}$ and not $\mathbf{A}^k\mathbf{b}$ — and take their span. It is a subspace for the usual reason, being a span. The index k counts **vectors**, not powers; the off-by-one is a convention, and it is the one that makes $\dim \mathcal{K}_k \leq k$ with equality in the typical case.

Examples. Take $F = \mathbb{R}$ throughout.

- **The identity.** For $\mathbf{A} = \mathbf{I}_n$ and any $\mathbf{b} \neq \mathbf{0}$, every $\mathbf{A}^j\mathbf{b}$ equals $\mathbf{b}$, so $\mathcal{K}_k(\mathbf{I}_n, \mathbf{b}) = \operatorname{span}(\mathbf{b})$ for every k. One product buys nothing, and neither do a hundred.
- **A companion matrix.** Let $\mathbf{Ae}_j = \mathbf{e}_{j+1}$ for $j \leq n-1$, as for the companion matrix

of Definition 9.5.3, and let $\mathbf{b} = \mathbf{e}_1$. Then $\mathbf{A}^j\mathbf{e}_1 = \mathbf{e}_{j+1}$ for $j \le n-1$, so $\mathcal{K}_k(\mathbf{A}, \mathbf{e}_1) = \operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_k)$ for $k \le n$, of dimension exactly k. Here every product buys a new dimension.

- **A diagonal matrix.** Let $\mathbf{A} = \operatorname{diag}(4, 3, 2, 1)$ and $\mathbf{b} = (1, 1, 1, 1)$. Then $\mathbf{A}^j\mathbf{b} = (4^j, 3^j, 2^j, 1)$, and these four vectors for $j = 0, 1, 2, 3$ form a Vandermonde matrix with distinct nodes, hence are independent (Theorem 6.8.1). So $\dim \mathcal{K}_k = k$ for $k \le 4$, and $\mathcal{K}_4 = \mathbb{R}^4$.
- **Degenerate cases.** $\mathcal{K}_1(\mathbf{A}, \mathbf{b}) = \operatorname{span}(\mathbf{b})$; and $\mathcal{K}_k(\mathbf{A}, \mathbf{0}) = \{\mathbf{0}\}$ for every k, which is why $\mathbf{b} \neq \mathbf{0}$ is assumed from here on.

Non-example by minimal change. Drop the middle vector of the list. Let $\mathbf{A} \in M_3(\mathbb{R})$ satisfy $\mathbf{A}\mathbf{e}_1 = \mathbf{e}_2$, $\mathbf{A}\mathbf{e}_2 = \mathbf{e}_3$, $\mathbf{A}\mathbf{e}_3 = \mathbf{0}$, and let $\mathbf{b} = \mathbf{e}_1$. The set $\operatorname{span}(\mathbf{b}, \mathbf{A}^2\mathbf{b}) = \operatorname{span}(\mathbf{e}_1, \mathbf{e}_3)$ is a perfectly good subspace, and it is not $\mathcal{K}_k(\mathbf{A}, \mathbf{b})$ for any k, since those are $\operatorname{span}(\mathbf{e}_1)$, $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_2)$ and $\mathbb{R}^3$. The clause that fails is that the powers be **consecutive**, and what it costs is everything: $\mathbf{A}\operatorname{span}(\mathbf{e}_1, \mathbf{e}_3) = \operatorname{span}(\mathbf{e}_2)$, which meets $\operatorname{span}(\mathbf{e}_1, \mathbf{e}_3)$ only at $\mathbf{0}$. The Krylov spaces, by contrast, are nested and almost invariant, which is the next proposition.

Why this definition. Chapter 9 already met the union of all of them. The cyclic subspace $Z(\mathbf{b}; \mathbf{A}) = \operatorname{span}(\mathbf{b}, \mathbf{A}\mathbf{b}, \mathbf{A}^2\mathbf{b}, \dots)$ of Definition 9.5.1 is the smallest $\mathbf{A}$-invariant subspace containing $\mathbf{b}$ (Proposition 9.5.1), and Theorem 9.5.2 says that the list stops growing exactly at the degree of the $\mathbf{A}$-annihilator $m_{\mathbf{A},\mathbf{b}}$. The Krylov space is that construction **truncated at** k, and the truncation is the whole point: $Z(\mathbf{b}; \mathbf{A})$ is a theoretical object, while $\mathcal{K}_k(\mathbf{A}, \mathbf{b})$ is what k units of work actually deliver.

Proposition 23.6.1 — Krylov Spaces: Nesting, Dimension, Invariance

Let $\mathbf{A} \in M_n(F)$ and $\mathbf{b} \in F^n$ with $\mathbf{b} \neq \mathbf{0}$, and let $d = \deg m_{\mathbf{A},\mathbf{b}} \ge 1$ be the degree of the $\mathbf{A}$-annihilator of $\mathbf{b}$ (Definition 9.5.2). Then, for every $k \ge 1$:

(a) $\mathcal{K}_k(\mathbf{A}, \mathbf{b}) = \{\, p(\mathbf{A})\mathbf{b} : p \in F[x],\ \deg p \le k-1 \,\}$, and $\mathcal{K}_k \subseteq \mathcal{K}_{k+1}$ and $\mathbf{A}\,\mathcal{K}_k \subseteq \mathcal{K}_{k+1}$;

(b) $\dim \mathcal{K}_k(\mathbf{A}, \mathbf{b}) = \min(k, d)$;

(c) $\mathcal{K}_{k+1} = \mathcal{K}_k$ if and only if $k \ge d$, and in that case $\mathcal{K}_k = Z(\mathbf{b}; \mathbf{A})$ is $\mathbf{A}$-invariant.

Idea. Everything is Theorem 9.5.2 read one index at a time. That theorem says $(\mathbf{b}, \mathbf{A}\mathbf{b}, \dots, \mathbf{A}^{d-1}\mathbf{b})$ is a basis of $Z(\mathbf{b}; \mathbf{A})$; so the first d vectors of our list are independent, and from $\mathbf{A}^d\mathbf{b}$ on they add nothing.

Proof.

(a) A linear combination $\sum_{j<k} a_j \mathbf{A}^j\mathbf{b}$ is $p(\mathbf{A})\mathbf{b}$ for $p = \sum_{j<k} a_j x^j$, and conversely, which is the first statement. The inclusion $\mathcal{K}_k \subseteq \mathcal{K}_{k+1}$ holds because the spanning list of $\mathcal{K}_k$ is part of that of $\mathcal{K}_{k+1}$. And $\mathbf{A}\mathbf{A}^j\mathbf{b} = \mathbf{A}^{j+1}\mathbf{b} \in \mathcal{K}_{k+1}$ for $j \le k-1$, so $\mathbf{A}$ maps a spanning list of $\mathcal{K}_k$ into $\mathcal{K}_{k+1}$, hence maps $\mathcal{K}_k$ into $\mathcal{K}_{k+1}$.

(b) By Theorem 9.5.2 (a), the list $(\mathbf{b}, \mathbf{A}\mathbf{b}, \dots, \mathbf{A}^{d-1}\mathbf{b})$ is a basis of $Z(\mathbf{b}; \mathbf{A})$. If $k \le d$, the first k entries of that list are a sublist of a basis, hence independent, so $\dim \mathcal{K}_k = k$. If $k > d$, then $\mathcal{K}_k \subseteq Z(\mathbf{b}; \mathbf{A})$, because every $\mathbf{A}^j\mathbf{b}$ lies there (Proposition 9.5.1 (a)); and $\mathcal{K}_k \supseteq \mathcal{K}_d = Z(\mathbf{b}; \mathbf{A})$, since $\mathcal{K}_d$ already contains a basis of it. So $\mathcal{K}_k = Z(\mathbf{b}; \mathbf{A})$ and $\dim \mathcal{K}_k = d$. In both cases $\dim \mathcal{K}_k = \min(k, d)$.

(c) ($\Leftarrow$) If $k \ge d$, then (b) gives $\dim \mathcal{K}_{k+1} = d = \dim \mathcal{K}_k$, and with $\mathcal{K}_k \subseteq \mathcal{K}_{k+1}$ from (a) this forces equality; and the common space is $Z(\mathbf{b}; \mathbf{A})$, $\mathbf{A}$-invariant by

Proposition 9.5.1 (b). ($\Rightarrow$) If $k < d$, then (b) gives $\dim \mathcal{K}_{k+1} = k+1 > k = \dim \mathcal{K}_k$, so the two differ. This proves the proposition.

■

Warning. **The list $\mathbf{b}, \mathbf{A}\mathbf{b}, \dots, \mathbf{A}^{k-1}\mathbf{b}$ is a basis of $\mathcal{K}_k$ and is useless as one.** By Section 4's reading of the power method (Theorem 23.4.1), $\mathbf{A}^j\mathbf{b}$ turns towards the dominant eigenvector as j grows, so the later vectors of the list are nearly parallel to each other. Even for $\mathbf{A} = \operatorname{diag}(4,3,2,1)$ and $\mathbf{b} = (1,1,1,1)$, with its modest ratio $\lambda_1/\lambda_2 = 4/3$, the angle between consecutive vectors of the list falls from 24 degrees to 8.9 degrees across those four vectors, and the matrix with those four columns has 2-norm condition number about 1200 — for a 4×4 problem with one-digit data. Independent they may be; in the arithmetic of Definition 23.1.1 the coordinates of a vector in that basis are computed with errors magnified by that condition number, which grows quickly with k. **A Krylov method never uses this basis.** It builds an orthonormal one instead, and that is the next subsection.

Quick check. Let $\mathbf{A} \in M_n(F)$ be invertible with $\mathbf{A}^2 = \mathbf{I}_n$, and let $\mathbf{b} \neq \mathbf{0}$ be a vector that is not an eigenvector of $\mathbf{A}$. What is $\dim \mathcal{K}_k(\mathbf{A}, \mathbf{b})$ for each $k \geq 1$?

Solution. It is 1 for $k = 1$ and 2 for every $k \geq 2$. The polynomial $x^2 - 1$ kills $\mathbf{b}$, so $m_{\mathbf{A},\mathbf{b}}$ divides it and has degree at most 2 (Definition 9.5.2). Degree 1 would mean $m_{\mathbf{A},\mathbf{b}} = x - \lambda$, that is $\mathbf{A}\mathbf{b} = \lambda\mathbf{b}$, making $\mathbf{b}$ an eigenvector, which is excluded; and $\deg m_{\mathbf{A},\mathbf{b}} \geq 1$ because $\mathbf{b} \neq \mathbf{0}$. So $d = 2$, and Proposition 23.6.1 (b) gives $\min(k, 2)$.

23.6.2 Arnoldi: Gram–Schmidt with a purpose

We want an orthonormal basis $\mathbf{q}_1, \dots, \mathbf{q}_k$ of $\mathcal{K}_k$, with the nesting preserved: $\operatorname{span}(\mathbf{q}_1, \dots, \mathbf{q}_j) = \mathcal{K}_j$ for every $j \leq k$. Running Theorem 10.2.2 on the list $\mathbf{b}, \mathbf{A}\mathbf{b}, \dots, \mathbf{A}^{k-1}\mathbf{b}$ would do it, and would inherit exactly the defect the warning describes, since it needs those vectors first.

The repair is one line long, and it is the idea of the whole subsection. Do not orthogonalize $\mathbf{A}^j\mathbf{b}$. Orthogonalize $\mathbf{A}\mathbf{q}_j$. The vector $\mathbf{A}\mathbf{q}_j$ lies in $\mathcal{K}_{j+1}$ by Proposition 23.6.1 (a), and subtracting its components along $\mathbf{q}_1, \dots, \mathbf{q}_j$ leaves a vector in $\mathcal{K}_{j+1}$ orthogonal to $\mathcal{K}_j$ — which is what the next basis vector must be. The powers of $\mathbf{A}$ are never formed.

Algorithm. **The Arnoldi process.** Given $\mathbf{A} \in M_n(F)$ and $\mathbf{b} \neq \mathbf{0}$, set $\mathbf{q}_1 = \mathbf{b}/\|\mathbf{b}\|$. For $j = 1, 2, \dots$:

$$h_{ij} = \langle \mathbf{A}\mathbf{q}_j, \mathbf{q}_i \rangle \quad (1 \leq i \leq j), \qquad \mathbf{w}_j = \mathbf{A}\mathbf{q}_j - \sum_{i=1}^{j} h_{ij}\mathbf{q}_i,$$

$$h_{j+1,j} = \|\mathbf{w}_j\|, \qquad \mathbf{q}_{j+1} = \mathbf{w}_j / h_{j+1,j} \quad \text{if } h_{j+1,j} \neq 0.$$

If $h_{j+1,j} = 0$ the process stops; this is called a **breakdown**, and the theorem below says it is good news.

Write $\mathbf{Q}_j = (\mathbf{q}_1 \mid \cdots \mid \mathbf{q}_j) \in M_{n \times j}(F)$, let $\mathbf{H}_k \in M_k(F)$ have entries h_{ij} for $i \leq j+1$ and zeros elsewhere, and let $\widetilde{\mathbf{H}}_k \in M_{(k+1)\times k}(F)$ be $\mathbf{H}_k$ with the extra row $h_{k+1,k}\mathbf{e}_k^{\top}$ appended at the

bottom.

Theorem 23.6.2 — The Arnoldi Process

Let $\mathbf{A} \in M_n(F)$, let $\mathbf{b} \in F^n$ be non-zero, let $d = \deg m_{\mathbf{A},\mathbf{b}}$, and run the Arnoldi process. Then the **Arnoldi relation**

$$\mathbf{A}\mathbf{Q}_k = \mathbf{Q}_k\mathbf{H}_k + h_{k+1,k}\,\mathbf{q}_{k+1}\mathbf{e}_k^{\top} \qquad (1 \le k \le d) \tag{23.6.1}$$

holds, the last term being $\mathbf{0}$ when $k = d$. Moreover:

(a) For every $j \le d$, the list $(\mathbf{q}_1, \dots, \mathbf{q}_j)$ is an orthonormal basis of $\mathcal{K}_j(\mathbf{A}, \mathbf{b})$; moreover $h_{j+1,j} > 0$ for $j < d$, and $h_{d+1,d} = 0$, so the process breaks down at step d and at no earlier step.

(b) For $1 \le k \le d$ we have $\mathbf{Q}_k^*\mathbf{Q}_k = \mathbf{I}_k$, and $\mathbf{H}_k = \mathbf{Q}_k^*\mathbf{A}\mathbf{Q}_k$ is **upper Hessenberg**. For $k < d$, Eq. 23.6.1 can also be written $\mathbf{A}\mathbf{Q}_k = \mathbf{Q}_{k+1}\widetilde{\mathbf{H}}_k$.

(c) A breakdown means an invariant subspace: if $h_{k+1,k} = 0$, then $\mathbf{A}\mathcal{K}_k \subseteq \mathcal{K}_k$, and every eigenvalue of $\mathbf{H}_k$ is an eigenvalue of $\mathbf{A}$.

Idea. Only one thing has to be checked, and it is the nesting: if $\mathbf{q}_1, \dots, \mathbf{q}_j$ is an orthonormal basis of $\mathcal{K}_j$, then $\mathbf{A}\mathbf{q}_j$ lies in $\mathcal{K}_{j+1}$ but generally not in $\mathcal{K}_j$, and what the step subtracts is exactly its $\mathcal{K}_j$-component. The matrix identity is then just the definition of $\mathbf{w}_j$ rearranged, column by column, and the Hessenberg shape is the statement that $\mathbf{A}\mathbf{q}_j$ needs only $\mathbf{q}_1, \dots, \mathbf{q}_{j+1}$ — never $\mathbf{q}_{j+2}$ — because $\mathbf{A}\mathcal{K}_j \subseteq \mathcal{K}_{j+1}$.

Proof.

(a) Induction on j. For $j = 1$, $\mathbf{q}_1 = \mathbf{b}/\|\mathbf{b}\|$ is a unit vector spanning $\mathcal{K}_1 = \operatorname{span}(\mathbf{b})$. Let $1 \le j$ and suppose $(\mathbf{q}_1, \dots, \mathbf{q}_j)$ is an orthonormal basis of $\mathcal{K}_j$. The subtraction in the process makes $\mathbf{w}_j$ orthogonal to each $\mathbf{q}_i$ with $i \le j$: for such i,

$$\langle \mathbf{w}_j, \mathbf{q}_i \rangle = \langle \mathbf{A}\mathbf{q}_j, \mathbf{q}_i \rangle - \sum_{l=1}^{j} h_{lj} \langle \mathbf{q}_l, \mathbf{q}_i \rangle = h_{ij} - h_{ij} = 0,$$

using orthonormality. Also $\mathbf{A}\mathbf{q}_j \in \mathbf{A}\mathcal{K}_j \subseteq \mathcal{K}_{j+1}$ by Proposition 23.6.1 (a), and each $\mathbf{q}_i \in \mathcal{K}_j \subseteq \mathcal{K}_{j+1}$, so $\mathbf{w}_j \in \mathcal{K}_{j+1}$.

Claim. $\mathcal{K}_{j+1} = \mathcal{K}_j + \operatorname{span}(\mathbf{A}\mathbf{q}_j)$.

Proof. ($\supseteq$) Both summands lie in $\mathcal{K}_{j+1}$, by Proposition 23.6.1 (a). ($\subseteq$) Since $\mathcal{K}_{j+1} = \mathcal{K}_j + \operatorname{span}(\mathbf{A}^j\mathbf{b})$, it is enough to place $\mathbf{A}^j\mathbf{b}$ on the right. Write $\mathbf{A}^{j-1}\mathbf{b} = \sum_{i \le j} c_i \mathbf{q}_i$, possible because $\mathbf{A}^{j-1}\mathbf{b} \in \mathcal{K}_j$ and the $\mathbf{q}_i$ are a basis of it. Applying $\mathbf{A}$,

$$\mathbf{A}^j\mathbf{b} = \sum_{i \le j} c_i\, \mathbf{A}\mathbf{q}_i,$$

and for $i \le j - 1$ we have $\mathbf{A}\mathbf{q}_i \in \mathbf{A}\mathcal{K}_i \subseteq \mathcal{K}_{i+1} \subseteq \mathcal{K}_j$. So only the term $c_j\mathbf{A}\mathbf{q}_j$ leaves $\mathcal{K}_j$.

■

Now $\mathbf{w}_j = \mathbf{0}$ if and only if $\mathbf{A}\mathbf{q}_j \in \mathcal{K}_j$, and by the Claim that happens if and only if $\mathcal{K}_{j+1} = \mathcal{K}_j$. Suppose first that $j < d$. Then $\dim \mathcal{K}_{j+1} = j+1 > j = \dim \mathcal{K}_j$ by Proposition 23.6.1 (b), so $\mathcal{K}_{j+1} \neq \mathcal{K}_j$ and $\mathbf{w}_j \neq \mathbf{0}$. Hence $h_{j+1,j} > 0$, and $\mathbf{q}_{j+1} = \mathbf{w}_j / h_{j+1,j}$ is a unit vector in $\mathcal{K}_{j+1}$ orthogonal to $\mathbf{q}_1, \dots, \mathbf{q}_j$. An orthogonal list of non-zero vectors is independent, so $(\mathbf{q}_1, \dots, \mathbf{q}_{j+1})$ is an orthonormal list of $j+1$ vectors in the $(j+1)$-dimensional space $\mathcal{K}_{j+1}$, hence a basis of it.

If instead $j = d$, then $\mathcal{K}_{d+1} = \mathcal{K}_d$ by Proposition 23.6.1 (c), so $\mathbf{A}\mathbf{q}_d \in \mathbf{A}\mathcal{K}_d \subseteq \mathcal{K}_{d+1} = \mathcal{K}_d$ and $\mathbf{w}_d = \mathbf{0}$. This gives (a).

(b), and Eq. 23.6.1. The columns of $\mathbf{Q}_k$ are orthonormal by (a), which is $\mathbf{Q}_k^* \mathbf{Q}_k = \mathbf{I}_k$. Rearranging the definition of $\mathbf{w}_j$,

$$\mathbf{A}\mathbf{q}_j = \sum_{i=1}^{j} h_{ij}\mathbf{q}_i + h_{j+1,j}\mathbf{q}_{j+1} = \sum_{i=1}^{j+1} h_{ij}\mathbf{q}_i,$$

for each $j \leq k$, where for $j = d$ the last term is $\mathbf{0}$. For $j < k$ the right-hand side is $\mathbf{Q}_k \mathbf{H}_k \mathbf{e}_j$, since column j of $\mathbf{H}_k$ has entries $h_{1j}, \dots, h_{j+1,j}$ and zeros below and $j+1 \leq k$; for $j = k$ it is $\mathbf{Q}_k \mathbf{H}_k \mathbf{e}_k + h_{k+1,k}\mathbf{q}_{k+1}$. Collecting the columns gives Eq. 23.6.1, and the form $\mathbf{A}\mathbf{Q}_k = \mathbf{Q}_{k+1}\widetilde{\mathbf{H}}_k$ is the same identity with the extra column of $\mathbf{Q}_{k+1}$ and the extra row of $\widetilde{\mathbf{H}}_k$ absorbing the last term. The entries h_{ij} with $i > j+1$ are zero by definition, which is exactly upper Hessenberg form. Finally, multiplying Eq. 23.6.1 on the left by $\mathbf{Q}_k^*$ and using $\mathbf{Q}_k^* \mathbf{Q}_k = \mathbf{I}_k$ and $\mathbf{Q}_k^* \mathbf{q}_{k+1} = \mathbf{0}$,

$$\mathbf{Q}_k^* \mathbf{A} \mathbf{Q}_k = \mathbf{H}_k + h_{k+1,k}\, \mathbf{Q}_k^* \mathbf{q}_{k+1} \mathbf{e}_k^{\top} = \mathbf{H}_k.$$

(c) If $h_{k+1,k} = 0$, then Eq. 23.6.1 reads $\mathbf{A}\mathbf{Q}_k = \mathbf{Q}_k \mathbf{H}_k$, so $\mathbf{A}\mathbf{q}_j \in \mathcal{K}_k$ for every $j \leq k$ and hence $\mathbf{A}\mathcal{K}_k \subseteq \mathcal{K}_k$. If $\mathbf{H}_k \mathbf{y} = \theta \mathbf{y}$ with $\mathbf{y} \neq \mathbf{0}$, put $\mathbf{x} = \mathbf{Q}_k \mathbf{y}$, which is non-zero because the columns of $\mathbf{Q}_k$ are independent; then $\mathbf{A}\mathbf{x} = \mathbf{A}\mathbf{Q}_k \mathbf{y} = \mathbf{Q}_k \mathbf{H}_k \mathbf{y} = \theta \mathbf{Q}_k \mathbf{y} = \theta \mathbf{x}$. This proves the theorem.

■

The cost of k steps is k matrix-vector products plus the orthogonalizations, which use about $4nj$ flops at step j — j inner products and j subtractions, about $2n$ flops each — so $O(nk^2)$ in total; and all $k+1$ vectors must be stored. Both grow with k, which is why Arnoldi is restarted in practice. For Hermitian $\mathbf{A}$ neither grows, and that is the next theorem.

23.6.3 Lanczos: the recurrence collapses to three terms

Theorem 23.6.3 — The Lanczos Recurrence

Let $\mathbf{A} \in M_n(\mathbb{C})$ be **Hermitian**, let $\mathbf{b} \neq \mathbf{0}$, and run the Arnoldi process. Then $\mathbf{H}_k$ is Hermitian for every $k \leq d$, hence **tridiagonal**, with real diagonal entries; writing $\alpha_j = h_{jj} \in \mathbb{R}$ and $\beta_j = h_{j+1,j}$, which is > 0 for $j < d$ and 0 for $j = d$, we have $h_{j,j+1} = \beta_j$ and

$$\mathbf{A}\mathbf{q}_j = \beta_{j-1}\mathbf{q}_{j-1} + \alpha_j\mathbf{q}_j + \beta_j\mathbf{q}_{j+1} \qquad (1 \le j \le d), \tag{23.6.2}$$

with $\beta_0\mathbf{q}_0$ read as $\mathbf{0}$ and $\beta_d\mathbf{q}_{d+1}$ as $\mathbf{0}$. Consequently $\mathbf{H}_k = \mathbf{T}_k$ is the real symmetric tridiagonal matrix with diagonal $(\alpha_1, \dots, \alpha_k)$ and off-diagonal $(\beta_1, \dots, \beta_{k-1})$, and each step of the process needs only $\mathbf{q}_{j-1}$ and $\mathbf{q}_j$.

Idea. Two facts collide. The matrix $\mathbf{H}_k = \mathbf{Q}_k^*\mathbf{A}\mathbf{Q}_k$ is Hermitian because $\mathbf{A}$ is, and it is upper Hessenberg by Theorem 23.6.2. A Hermitian matrix with zeros below the subdiagonal has zeros above the superdiagonal too, by conjugating. Everything else is bookkeeping. The reason is worth naming separately: $h_{ij} = \langle \mathbf{A}\mathbf{q}_j, \mathbf{q}_i \rangle$ lets $\mathbf{A}$ move to the other slot for free, and $\mathbf{A}\mathbf{q}_i$ lives one index further along than $\mathbf{q}_i$ does.

Proof. By Theorem 23.6.2 (b), $\mathbf{H}_k = \mathbf{Q}_k^*\mathbf{A}\mathbf{Q}_k$, so $\mathbf{H}_k^* = \mathbf{Q}_k^*\mathbf{A}^*\mathbf{Q}_k = \mathbf{Q}_k^*\mathbf{A}\mathbf{Q}_k = \mathbf{H}_k$ and $\mathbf{H}_k$ is Hermitian; in particular its diagonal entries are real.

Let $i \le j - 2$. Since $\mathbf{A}^* = \mathbf{A}$ is self-adjoint,

$$h_{ij} = \langle \mathbf{A}\mathbf{q}_j, \mathbf{q}_i \rangle = \langle \mathbf{q}_j, \mathbf{A}\mathbf{q}_i \rangle.$$

Now $\mathbf{q}_i \in \mathcal{K}_i$, so $\mathbf{A}\mathbf{q}_i \in \mathcal{K}_{i+1} \subseteq \mathcal{K}_{j-1}$ by Proposition 23.6.1 (a) and $i+1 \le j-1$, while $\mathbf{q}_j$ is orthogonal to $\mathcal{K}_{j-1}$ by Theorem 23.6.2 (a). Hence $h_{ij} = 0$ whenever $i \le j-2$. Together with $h_{ij} = 0$ for $i > j+1$, this leaves only $i \in \{j-1, j, j+1\}$, so $\mathbf{H}_k$ is tridiagonal. Being Hermitian, $h_{j,j+1} = \overline{h_{j+1,j}} = \beta_j$, which is real and positive. The displayed recurrence Eq. 23.6.2 is then the expansion $\mathbf{A}\mathbf{q}_j = \sum_i h_{ij}\mathbf{q}_i$ of Theorem 23.6.2 (b) with only three surviving terms; and $\mathbf{H}_k$ has real entries, is symmetric and is tridiagonal, as claimed. Since the step needs only $h_{j-1,j} = \beta_{j-1}$, $h_{jj} = \alpha_j$ and $\mathbf{q}_{j-1}, \mathbf{q}_j$, this proves the theorem. ∎

This is Chapter 10's three-term recurrence, and for the same reason. Chapter 10 §10 built the monic orthogonal polynomials for an inner product on $\mathbb{R}[x]$ and found (Theorem 10.10.3) that $p_{k+1} = (x - a_k)p_k - b_k p_{k-1}$, with only three terms; the reason given there was Proposition 10.10.1, "multiplication by x moves from one slot to the other for free". The two statements are the same statement. Given Hermitian $\mathbf{A}$ and $\mathbf{b} \neq \mathbf{0}$, define on $\mathbb{R}[x]$

$$\langle p, q \rangle_{\mathbf{b}} := \langle p(\mathbf{A})\mathbf{b}, q(\mathbf{A})\mathbf{b} \rangle.$$

This is symmetric and bilinear, and on $\mathbb{R}[x]_{\le d-1}$ it is positive definite: $\langle p, p \rangle_{\mathbf{b}} = \|p(\mathbf{A})\mathbf{b}\|^2$ vanishes only when $p(\mathbf{A})\mathbf{b} = \mathbf{0}$, which by Definition 9.5.2 means $m_{\mathbf{A},\mathbf{b}} \mid p$, impossible for a non-zero p of degree below d. Multiplication by x is symmetric for it, since $\mathbf{A}$ is Hermitian:

$$\langle xp, q \rangle_{\mathbf{b}} = \langle \mathbf{A}\, p(\mathbf{A})\mathbf{b}, q(\mathbf{A})\mathbf{b} \rangle = \langle p(\mathbf{A})\mathbf{b}, \mathbf{A}\, q(\mathbf{A})\mathbf{b} \rangle = \langle p, xq \rangle_{\mathbf{b}}.$$

Now Proposition 23.6.1 (a) says $\mathbf{q}_{j+1}$ is $r(\mathbf{A})\mathbf{b}$ for some r of degree at most j, and orthogonality to $\mathcal{K}_j$ says $\langle r, s \rangle_{\mathbf{b}} = 0$ for every s of degree below j. So for $j \le d - 1$ the polynomial r is a scalar multiple of the j-th monic orthogonal polynomial p_j for $\langle \cdot, \cdot \rangle_{\mathbf{b}}$, and Eq. 23.6.2, at those indices, **is** the recurrence of Theorem 10.10.3 rewritten in terms of the vectors $p_j(\mathbf{A})\mathbf{b}$ — read, as that theorem's node inner product is read, only in the range of degrees where the form is positive definite. The last step $j = d$ lies outside that range: there the monic polynomial of degree d orthogonal to everything of lower degree is $m_{\mathbf{A},\mathbf{b}}$ itself, and $\langle m_{\mathbf{A},\mathbf{b}}, m_{\mathbf{A},\mathbf{b}} \rangle_{\mathbf{b}} = 0$. A third appearance of the same three terms is Chapter 6's: by Theorem 6.8.3, the characteristic

polynomials $D_k(x) = \det(x\mathbf{I}_k - \mathbf{T}_k)$ of the leading blocks satisfy

$$D_k = (x - \alpha_k)D_{k-1} - \beta_{k-1}^2 D_{k-2},$$

which is Theorem 10.10.3 with $a_{k-1} = \alpha_k$ and $b_{k-1} = \beta_{k-1}^2 > 0$. The Lanczos coefficients, the orthogonal polynomials and the determinants of the tridiagonal blocks are one object seen three ways.

Example. (A breakdown at step two)

Let $\mathbf{A} = \begin{pmatrix} 3 & 1 & 1 \\ 1 & 3 & 1 \\ 1 & 1 & 3 \end{pmatrix}$ and $\mathbf{b} = \mathbf{e}_1$. Run the Lanczos recurrence of Theorem 23.6.3, and identify what it finds.

Solution. $\mathbf{q}_1 = \mathbf{e}_1$, and $\mathbf{A}\mathbf{q}_1 = (3, 1, 1)$. So $\alpha_1 = \langle \mathbf{A}\mathbf{q}_1, \mathbf{q}_1 \rangle = 3$ and

$$\mathbf{w}_1 = (3, 1, 1) - 3(1, 0, 0) = (0, 1, 1), \qquad \beta_1 = \sqrt{2}, \qquad \mathbf{q}_2 = \tfrac{1}{\sqrt{2}}(0, 1, 1).$$

Next, $\mathbf{A}\mathbf{q}_2 = \frac{1}{\sqrt{2}}(2, 4, 4)$, so $\alpha_2 = \langle \mathbf{A}\mathbf{q}_2, \mathbf{q}_2 \rangle = \frac{1}{2}(0 + 4 + 4) = 4$ and

$$\mathbf{w}_2 = \tfrac{1}{\sqrt{2}}(2, 4, 4) - 4 \cdot \tfrac{1}{\sqrt{2}}(0, 1, 1) - \sqrt{2}\,(1, 0, 0) = \tfrac{1}{\sqrt{2}}(2, 0, 0) - \sqrt{2}(1, 0, 0) = \mathbf{0}.$$

The process breaks down at step 2, so $d = 2$ and $\mathcal{K}_2$ is $\mathbf{A}$-invariant, by Theorem 23.6.2 (a), (c). Then

$$\mathbf{T}_2 = \begin{pmatrix} 3 & \sqrt{2} \\ \sqrt{2} & 4 \end{pmatrix}, \qquad p_{\mathbf{T}_2}(x) = (x - 3)(x - 4) - 2 = x^2 - 7x + 10,$$

with roots 5 and 2. And indeed $\operatorname{spec}(\mathbf{A}) = \{5, 2\}$, with 5 simple and 2 of multiplicity 2: the two steps have produced both eigenvalues exactly. This is Theorem 23.6.2 (c) in action, and it is also Proposition 23.6.1 (b) with $d = \deg m_{\mathbf{A},\mathbf{e}_1} = 2$, since $m_{\mathbf{A}} = (x - 5)(x - 2)$ and neither factor alone kills $\mathbf{e}_1$.

23.6.4 Ritz values

An invariant subspace would give eigenvalues exactly. A Krylov space is an **almost** invariant subspace — by Eq. 23.6.1 it fails to be invariant only through the single vector $h_{k+1,k}\mathbf{q}_{k+1}$ — so it should give almost-eigenvalues, and it should be possible to say how almost.

Definition 23.6.2 — Ritz Values and Ritz Vectors

Let $\mathbf{A} \in M_n(F)$, let $\mathbf{Q}_k \in M_{n\times k}(F)$ have orthonormal columns, and put $\mathbf{H}_k = \mathbf{Q}_k^* \mathbf{A} \mathbf{Q}_k$. The eigenvalues $\theta_1, \dots, \theta_k$ of $\mathbf{H}_k$ are the **Ritz values** of $\mathbf{A}$ from the subspace $\operatorname{span}(\mathbf{q}_1, \dots, \mathbf{q}_k)$, and for an eigenvector $\mathbf{y}$ of $\mathbf{H}_k$ with $\mathbf{H}_k\mathbf{y} = \theta\mathbf{y}$ and $\|\mathbf{y}\| = 1$, the vector $\mathbf{x} = \mathbf{Q}_k\mathbf{y}$ is the corresponding **Ritz vector**; the pair $(\theta, \mathbf{x})$ is a **Ritz pair**.

In words: project the problem onto the subspace, solve the small problem exactly, and lift the answer back. The Ritz values depend on the subspace and not on which orthonormal basis of it

we chose: replacing $\mathbf{Q}_k$ by $\mathbf{Q}_k\mathbf{V}$ with $\mathbf{V}$ unitary replaces $\mathbf{H}_k$ by $\mathbf{V}^*\mathbf{H}_k\mathbf{V}$, which has the same eigenvalues. Note that $\|\mathbf{x}\| = \|\mathbf{Q}_k\mathbf{y}\| = \|\mathbf{y}\| = 1$, since $\mathbf{Q}_k$ has orthonormal columns.

Theorem 23.6.4 — Ritz Values Interlace, and Their Residual Is One Number

Let $\mathbf{A} \in M_n(\mathbb{C})$ be Hermitian with eigenvalues $\lambda_1(\mathbf{A}) \geq \cdots \geq \lambda_n(\mathbf{A})$, let $1 \leq k \leq d$, and let $\theta_1 \geq \cdots \geq \theta_k$ be the Ritz values from $\mathcal{K}_k(\mathbf{A}, \mathbf{b})$, that is, the eigenvalues of $\mathbf{T}_k$.

(a) $\lambda_i(\mathbf{A}) \;\geq\; \theta_i \;\geq\; \lambda_{i+n-k}(\mathbf{A})$ for $1 \leq i \leq k$.

(b) If $\mathbf{T}_k\mathbf{y} = \theta\mathbf{y}$ with $\|\mathbf{y}\| = 1$ and $\mathbf{x} = \mathbf{Q}_k\mathbf{y}$, then

$$\mathbf{A}\mathbf{x} - \theta\mathbf{x} = \beta_k\, y_k\, \mathbf{q}_{k+1}, \qquad \text{so} \qquad \|\mathbf{A}\mathbf{x} - \theta\mathbf{x}\| = \beta_k\, |y_k|,$$

where y_k is the last coordinate of $\mathbf{y}$ and $\beta_k = h_{k+1,k}$, with $\beta_d\mathbf{q}_{d+1}$ read as $\mathbf{0}$.

Idea. For (a), the obstacle is that $\mathbf{T}_k = \mathbf{Q}_k^*\mathbf{A}\mathbf{Q}_k$ is a compression, not a principal submatrix, and Chapter 16's interlacing is about principal submatrices. The repair is to complete $\mathbf{Q}_k$ to a unitary matrix: then $\mathbf{T}_k$ *is* the leading principal submatrix of a matrix unitarily similar to $\mathbf{A}$, and Corollary 16.4.3 applies unchanged. For (b), just apply Eq. 23.6.1 to $\mathbf{y}$ and watch the two $\mathbf{Q}_k\mathbf{T}_k\mathbf{y}$ terms cancel.

Proof.

(a) Extend $\mathbf{q}_1, \ldots, \mathbf{q}_k$ to an orthonormal basis $\mathbf{q}_1, \ldots, \mathbf{q}_n$ of $\mathbb{C}^n$, which is possible by Theorem 10.2.2 applied to any extension of the list to a basis (Theorem 1.6.5), and let $\mathbf{U} = (\mathbf{q}_1 \mid \cdots \mid \mathbf{q}_n)$, which is unitary. Then $\mathbf{B} = \mathbf{U}^*\mathbf{A}\mathbf{U}$ is Hermitian and unitarily similar to $\mathbf{A}$, so $\lambda_i(\mathbf{B}) = \lambda_i(\mathbf{A})$ for every i. Its entries are $b_{ij} = \langle \mathbf{A}\mathbf{q}_j, \mathbf{q}_i \rangle$, and for $i, j \leq k$ these are exactly the entries of $\mathbf{Q}_k^*\mathbf{A}\mathbf{Q}_k = \mathbf{T}_k$. So $\mathbf{T}_k = \mathbf{B}_{I,I}$ with $I = \{1, \ldots, k\}$, a principal submatrix of $\mathbf{B}$ obtained by deleting $m = n - k$ rows and the same columns. Now Corollary 16.4.3 gives

$$\lambda_i(\mathbf{B}) \;\geq\; \lambda_i(\mathbf{T}_k) \;\geq\; \lambda_{i+m}(\mathbf{B}) \qquad (1 \leq i \leq k),$$

which is the assertion, since $\lambda_i(\mathbf{T}_k) = \theta_i$ and $\lambda_i(\mathbf{B}) = \lambda_i(\mathbf{A})$.

(b) By Eq. 23.6.1, $\mathbf{A}\mathbf{Q}_k = \mathbf{Q}_k\mathbf{T}_k + \beta_k\mathbf{q}_{k+1}\mathbf{e}_k^\top$. Applying both sides to $\mathbf{y}$ and using $\mathbf{T}_k\mathbf{y} = \theta\mathbf{y}$ and $\mathbf{e}_k^\top\mathbf{y} = y_k$,

$$\mathbf{A}\mathbf{x} = \mathbf{A}\mathbf{Q}_k\mathbf{y} = \mathbf{Q}_k\mathbf{T}_k\mathbf{y} + \beta_k\, y_k\, \mathbf{q}_{k+1} = \theta\, \mathbf{Q}_k\mathbf{y} + \beta_k y_k \mathbf{q}_{k+1} = \theta\mathbf{x} + \beta_k y_k \mathbf{q}_{k+1}.$$

Subtracting $\theta\mathbf{x}$ gives the displayed identity, and taking norms gives the second form, since $\|\mathbf{q}_{k+1}\| = 1$ and $\beta_k \geq 0$. (For $k = d$ the right-hand side is $\mathbf{0}$, and the Ritz pair is an exact eigenpair, as Theorem 23.6.2 (c) already said.) This proves the theorem.

■

Part (b) is where the chapter's perturbation theory pays off, and it pays off for free. The residual $\|\mathbf{A}\mathbf{x} - \theta\mathbf{x}\|$ is the one quantity Chapter 19 §06 asks for, and here it is available **without forming $\mathbf{A}\mathbf{x}$**: it is the product of the number β_k the process has just computed and one coordinate of the small eigenvector $\mathbf{y}$. So Theorem 19.6.1 applies verbatim, and says that $\mathbf{A}$

has an eigenvalue within $\beta_k|y_k|$ of θ. Better still, $\theta = \langle \mathbf{A}\mathbf{x}, \mathbf{x}\rangle$ is the Rayleigh quotient of $\mathbf{x}$ — because $\langle \mathbf{A}\mathbf{x}, \mathbf{x}\rangle = \mathbf{y}^*\mathbf{Q}_k^*\mathbf{A}\mathbf{Q}_k\mathbf{y} = \mathbf{y}^*\mathbf{T}_k\mathbf{y} = \theta$ — so Theorem 19.6.2 applies too, and turns the same number into a bound of size $(\beta_k|y_k|)^2$ divided by the distance to the rest of the spectrum. Nothing in this section had to be proved twice.

Warning. **A Ritz value that happens to equal an eigenvalue is not a converged one, and for a non-Hermitian $\mathbf{A}$ there is no interlacing to fall back on.** Take

$$\mathbf{A} = \begin{pmatrix} 2 & 1 & 1 \\ 0 & 2 & 1 \\ 0 & 0 & 1 \end{pmatrix}, \qquad \mathbf{b} = \mathbf{e}_3.$$

Two Arnoldi steps give $\mathbf{q}_1 = \mathbf{e}_3$, $\mathbf{q}_2 = \frac{1}{\sqrt{2}}(1,1,0)$ and $\mathbf{H}_2 = \begin{pmatrix} 1 & 0 \\ \sqrt{2} & \frac{5}{2} \end{pmatrix}$, hence the Ritz values $\frac{5}{2}$ and 1; Exercise (B2: Two Arnoldi steps) works the details. The second is an exact eigenvalue of $\mathbf{A}$ — and its Ritz vector $\frac{1}{\sqrt{17}}(-2,-2,3)$ is not an eigenvector of $\mathbf{A}$, the residual being $\sqrt{34}/17 \approx 0.343$, nowhere near zero. What certifies convergence is the residual, never the agreement of a number with a number. Part (a) of Theorem 23.6.4 needs $\mathbf{A}$ Hermitian; without that hypothesis there is no interlacing and, by Theorem 19.4.4, a residual bound carries the factor $\kappa_2(\mathbf{X})$.

Example. (Ritz values closing in on the extremes)

Let $\mathbf{A} = \operatorname{diag}(4,3,2,1)$ and $\mathbf{b} = (1,1,1,1)$. Compute the Lanczos coefficients, the Ritz values for $k = 1,2,3$, and the residual of the largest Ritz pair at $k = 3$.

Solution. Here $\mathbf{q}_1 = \frac{1}{2}(1,1,1,1)$ and $\mathbf{A}\mathbf{q}_1 = \frac{1}{2}(4,3,2,1)$, so $\alpha_1 = \frac{1}{4}(4+3+2+1) = \frac{5}{2}$. Then

$$\mathbf{w}_1 = \tfrac{1}{2}(4,3,2,1) - \tfrac{5}{2}\cdot\tfrac{1}{2}(1,1,1,1) = \tfrac{1}{4}(3,1,-1,-3), \qquad \beta_1 = \frac{\sqrt{20}}{4} = \frac{\sqrt{5}}{2},$$

and $\mathbf{q}_2 = \frac{1}{\sqrt{20}}(3,1,-1,-3)$. Continuing in the same way gives $\alpha_2 = \alpha_3 = \alpha_4 = \frac{5}{2}$ as well, together with $\beta_2 = \frac{2}{\sqrt{5}}$ and $\beta_3 = \frac{3}{2\sqrt{5}}$.

The repetition of $\frac{5}{2}$ is a symmetry, not an accident. Let $\mathbf{S}$ be the reversal permutation matrix, $\mathbf{S}\mathbf{e}_j = \mathbf{e}_{5-j}$, and put $\mathbf{B} = \mathbf{A} - \frac{5}{2}\mathbf{I} = \operatorname{diag}(\frac{3}{2}, \frac{1}{2}, -\frac{1}{2}, -\frac{3}{2})$. Then $\mathbf{S}$ is orthogonal with $\mathbf{S}^2 = \mathbf{I}$, and $\mathbf{S}\mathbf{B}\mathbf{S} = -\mathbf{B}$, $\mathbf{S}\mathbf{b} = \mathbf{b}$. We show by induction, simultaneously, that $\mathbf{S}\mathbf{q}_j = \varepsilon_j\mathbf{q}_j$ with $\varepsilon_j = (-1)^{j-1}$ and that $\alpha_j = \frac{5}{2}$. The first holds at $j = 1$. Given it at j,

$$\alpha_j - \tfrac{5}{2} = \langle \mathbf{B}\mathbf{q}_j, \mathbf{q}_j\rangle = \langle \mathbf{S}\mathbf{B}\mathbf{q}_j, \mathbf{S}\mathbf{q}_j\rangle = \langle \mathbf{S}\mathbf{B}\mathbf{S}(\mathbf{S}\mathbf{q}_j), \mathbf{S}\mathbf{q}_j\rangle = -\varepsilon_j^2\langle \mathbf{B}\mathbf{q}_j, \mathbf{q}_j\rangle,$$

and $\varepsilon_j^2 = 1$, so this number equals its own negative and $\alpha_j = \frac{5}{2}$. The Lanczos step then reads $\mathbf{w}_j = \mathbf{B}\mathbf{q}_j - \beta_{j-1}\mathbf{q}_{j-1}$, and applying $\mathbf{S}$ with $\varepsilon_{j-1} = -\varepsilon_j$ gives $\mathbf{S}\mathbf{w}_j = -\varepsilon_j\mathbf{w}_j$, so $\mathbf{S}\mathbf{q}_{j+1} = \varepsilon_{j+1}\mathbf{q}_{j+1}$. The Ritz values are the eigenvalues of the leading blocks of $\mathbf{T}_4$:

k	Ritz values	check against $4,3,2,1$
1	$\frac{5}{2}$	$4 \ge 2.5 \ge 1$
2	$\frac{5\pm\sqrt{5}}{2} \approx 3.6180,\ 1.3820$	$4 \ge 3.618 \ge 2$; $3 \ge 1.382 \ge 1$

3	$\frac{5}{2} \pm \frac{\sqrt{205}}{10} \approx 3.9318,\ 1.0682,$ and $\frac{5}{2}$	$4 \ge 3.932 \ge 3;\ 3 \ge 2.5 \ge 2;$ $2 \ge 1.068 \ge 1$
4	$4, 3, 2, 1$	exact

Every row obeys Theorem 23.6.4 (a), with $m = n - k$ shifting the index on the right. The extreme Ritz values close in on 4 and 1 fast, and the interior ones lag: at $k = 3$ the outer two are within 0.07 of 4 and 1, while the single interior value $\frac{5}{2}$ is half a unit from each of 3 and 2.

The residual at $k = 3$. The eigenvector of $\mathbf{T}_3$ for $\theta_1 = \frac{5}{2} + \frac{\sqrt{205}}{10}$ is, normalized,

$$\mathbf{y} = \left(\tfrac{5}{\sqrt{82}},\ \tfrac{1}{\sqrt{2}},\ \tfrac{4}{\sqrt{82}}\right),$$

so Theorem 23.6.4 (b) gives $\|\mathbf{A}\mathbf{x} - \theta_1\mathbf{x}\| = \beta_3|y_3| = \frac{3}{2\sqrt{5}} \cdot \frac{4}{\sqrt{82}} = \frac{3\sqrt{410}}{205} \approx 0.2963$. By Theorem 19.6.1, $\mathbf{A}$ has an eigenvalue within 0.2963 of 3.9318; the truth is 4, at distance 0.0682, so the certificate costs a factor of about 4. Suppose we also know that $\mathbf{A}$ has no eigenvalue in the open interval $(3, 4)$. Then Theorem 19.6.2 (b) with $\alpha = 3$ improves the upper end to

$$\theta_1 + \frac{(0.2963)^2}{3.9318 - 3} = 3.9318 + 0.0942 = 4.0260,$$

and the lower end is θ_1 itself by interlacing. The bracket $[3.9318,\ 4.0260]$ has width 0.094 where the residual bound gave 0.593. That is the quadratic gain of Chapter 19 §06, obtained here from one number the process had already produced.

23.6.5 How fast the extreme Ritz values converge

The example suggests the extremes converge quickly. Here is why, and how much of it we can prove.

Theorem 23.6.5 — A Rate for the Largest Ritz Value

Let $\mathbf{A} \in M_n(\mathbb{C})$ be Hermitian with eigenvalues $\lambda_1 > \lambda_2 \ge \cdots \ge \lambda_n$ and an orthonormal eigenbasis $\mathbf{v}_1, \dots, \mathbf{v}_n$. Let $\mathbf{b}$ be a unit vector with $\mathbf{b} = \sum_i c_i \mathbf{v}_i$ and $c_1 \neq 0$, and put

$$\tau^2 = \frac{\sum_{i \ge 2} |c_i|^2}{|c_1|^2}, \qquad \rho = \frac{\lambda_2 - \lambda_n}{2\lambda_1 - \lambda_2 - \lambda_n} \in [0, 1).$$

Then the largest Ritz value $\theta_1^{(k)}$ from $\mathcal{K}_k(\mathbf{A}, \mathbf{b})$ satisfies, for $1 \le k \le d$,

$$0 \ \le\ \lambda_1 - \theta_1^{(k)} \ \le\ (\lambda_1 - \lambda_n)\, \tau^2\, \rho^{2(k-1)},$$

and $\theta_1^{(k)}$ is non-decreasing in k.

Idea. Three moves. ① The largest Ritz value is the largest Rayleigh quotient **over the Krylov space**, by the Rayleigh principle transported through $\mathbf{Q}_k$. ② Every vector of the Krylov space is $p(\mathbf{A})\mathbf{b}$ for a polynomial of degree below k, so we may choose p and get a bound for free: whichever p makes p large at λ_1 and small at the other eigenvalues gives a good one. ③ Take the simplest such p, the $(k-1)$-st power of x minus the

midpoint of $[\lambda_n, \lambda_2]$. That is not the best choice, and the best one is the subject of the next section.

Proof. **Step 1.** $\theta_1^{(k)} = \max\{R_{\mathbf{A}}(\mathbf{x}) : \mathbf{x} \in \mathcal{K}_k(\mathbf{A}, \mathbf{b}),\ \mathbf{x} \neq \mathbf{0}\}$. Indeed $\theta_1^{(k)} = \lambda_1(\mathbf{T}_k) = \max_{\mathbf{y}\neq\mathbf{0}} R_{\mathbf{T}_k}(\mathbf{y})$ by Proposition 16.1.1, and the map $\mathbf{y} \mapsto \mathbf{Q}_k\mathbf{y}$ is a bijection from $\mathbb{C}^k \setminus \{\mathbf{0}\}$ onto $\mathcal{K}_k \setminus \{\mathbf{0}\}$, because the columns of $\mathbf{Q}_k$ are a basis of $\mathcal{K}_k$ (Theorem 23.6.2 (a)). Under it, with $\mathbf{x} = \mathbf{Q}_k\mathbf{y}$,

$$\langle \mathbf{A}\mathbf{x}, \mathbf{x}\rangle = \mathbf{y}^*\mathbf{Q}_k^*\mathbf{A}\mathbf{Q}_k\mathbf{y} = \mathbf{y}^*\mathbf{T}_k\mathbf{y}, \qquad \langle \mathbf{x}, \mathbf{x}\rangle = \mathbf{y}^*\mathbf{Q}_k^*\mathbf{Q}_k\mathbf{y} = \mathbf{y}^*\mathbf{y},$$

so $R_{\mathbf{A}}(\mathbf{x}) = R_{\mathbf{T}_k}(\mathbf{y})$ and the two maxima agree. Monotonicity in k follows at once from $\mathcal{K}_k \subseteq \mathcal{K}_{k+1}$ (Proposition 23.6.1 (a)), and $\theta_1^{(k)} \leq \lambda_1$ from Proposition 16.1.1 applied on all of $\mathbb{C}^n$ — which is also Theorem 23.6.4 (a) at $i = 1$.

Step 2. Let $p \in \mathbb{R}[x]$ have $\deg p \leq k-1$ and $p(\lambda_1) \neq 0$, and put $\mathbf{x} = p(\mathbf{A})\mathbf{b}$. Then $\mathbf{x} \in \mathcal{K}_k$ by Proposition 23.6.1 (a), and $\mathbf{x} = \sum_i c_i p(\lambda_i)\mathbf{v}_i$ since $\mathbf{A}\mathbf{v}_i = \lambda_i\mathbf{v}_i$. The list $(\mathbf{v}_i)$ being orthonormal, Theorem 10.2.1 gives

$$R_{\mathbf{A}}(\mathbf{x}) = \frac{\sum_i |c_i|^2 p(\lambda_i)^2 \lambda_i}{\sum_i |c_i|^2 p(\lambda_i)^2},$$

and $\mathbf{x} \neq \mathbf{0}$ because its first coefficient $c_1 p(\lambda_1)$ is non-zero. Subtracting from λ_1,

$$\lambda_1 - R_{\mathbf{A}}(\mathbf{x}) = \frac{\sum_{i\geq 2} |c_i|^2 p(\lambda_i)^2 (\lambda_1 - \lambda_i)}{\sum_i |c_i|^2 p(\lambda_i)^2},$$

the term $i = 1$ having vanished from the numerator. Every factor $\lambda_1 - \lambda_i$ is at most $\lambda_1 - \lambda_n$; and the denominator is at least its single term $|c_1|^2 p(\lambda_1)^2$, all terms being non-negative. Hence

$$\begin{aligned} \lambda_1 - R_{\mathbf{A}}(\mathbf{x}) &\leq (\lambda_1 - \lambda_n)\, \frac{\sum_{i\geq 2} |c_i|^2 p(\lambda_i)^2}{|c_1|^2 p(\lambda_1)^2} \\ &\leq (\lambda_1 - \lambda_n)\, \tau^2 \max_{i\geq 2} \Big(\frac{p(\lambda_i)}{p(\lambda_1)}\Big)^2. \end{aligned} \tag{$*$}$$

By Step 1, $\lambda_1 - \theta_1^{(k)} \leq \lambda_1 - R_{\mathbf{A}}(\mathbf{x})$.

Step 3. Take $\mu = \frac{1}{2}(\lambda_2 + \lambda_n)$, the midpoint of the interval holding the unwanted eigenvalues, and $p(x) = (x - \mu)^{k-1}$, of degree $k-1$. For $i \geq 2$ we have $\lambda_n \leq \lambda_i \leq \lambda_2$, so $|\lambda_i - \mu| \leq \frac{1}{2}(\lambda_2 - \lambda_n)$. And

$$\lambda_1 - \mu = \tfrac{1}{2}(\lambda_2 - \lambda_n) + (\lambda_1 - \lambda_2) > \tfrac{1}{2}(\lambda_2 - \lambda_n) \geq 0,$$

using $\lambda_1 > \lambda_2$; in particular $p(\lambda_1) = (\lambda_1 - \mu)^{k-1} \neq 0$. Therefore

$$\max_{i\geq 2} \Big|\frac{p(\lambda_i)}{p(\lambda_1)}\Big| \leq \Big(\frac{(\lambda_2 - \lambda_n)/2}{\lambda_1 - \mu}\Big)^{k-1} = \rho^{k-1},$$

since $2(\lambda_1 - \mu) = 2\lambda_1 - \lambda_2 - \lambda_n$. Substituting into $(*)$ gives the bound, and $\rho < 1$ because $\lambda_1 > \lambda_2$. This proves the theorem.

■

For $\mathbf{A} = \mathrm{diag}(4,3,2,1)$ and $\mathbf{b} = (1,1,1,1)/2$ the constants are $\tau^2 = 3$, $\lambda_1 - \lambda_n = 3$ and $\rho = \frac{1}{2}$, so the bound reads $9 \cdot 4^{-(k-1)}$: the values $9, 2.25, 0.5625$ for $k = 1,2,3$, against the true gaps 1.5, 0.382, 0.068 of Example (Ritz values closing in on the extremes). The bound is correct and loose, and the looseness is in Step 3.

It is worth naming what ρ is. Assume for the rest of this subsection that $\lambda_2 > \lambda_n$, which the theorem does not require; if instead $\lambda_2 = \lambda_n$, then $\rho = 0$ and the bound of Theorem 23.6.5 is already as strong as this route can make it. Put

$$\gamma = \frac{\lambda_1 - \lambda_2}{\lambda_2 - \lambda_n},$$

the size of the gap above λ_2 measured against the spread of the rest. Then $2\lambda_1 - \lambda_2 - \lambda_n = 2(\lambda_1 - \lambda_2) + (\lambda_2 - \lambda_n) = (\lambda_2 - \lambda_n)(1 + 2\gamma)$, so

$$\rho = \frac{1}{1 + 2\gamma}.$$

(For $\mathbf{A} = \mathrm{diag}(4,3,2,1)$, $\gamma = \frac{1}{2}$ and $\rho = \frac{1}{2}$.) So Step 3 buys a factor $(1 + 2\gamma)^{-(k-1)}$ per unit of k, and a small gap makes it nearly worthless.

What is not proved here. The polynomial of Step 3 is not the best one. Minimizing $\max_{i \geq 2} |p(\lambda_i)/p(\lambda_1)|$ over the polynomials of degree at most $k-1$ with $p(\lambda_1) = 1$ is a question about how small a polynomial can be kept on an interval while staying large at a point outside it, and its answer is the Chebyshev polynomial T_{k-1}, shifted and scaled to that interval. The resulting estimate, due to Kaniel, Paige and Saad, is

$$0 \leq \lambda_1 - \theta_1^{(k)} \leq \frac{(\lambda_1 - \lambda_n)\,\tau^2}{\big(T_{k-1}(1 + 2\gamma)\big)^2}.$$

The next section defines the Chebyshev polynomials and proves the two facts this bound rests on: that T_k stays within 1 on $[-1,1]$, and that it grows geometrically just outside it; the substitution into $(*)$ is then immediate, but **we do not carry it out here, and nothing in this section depends on it.** The reason it is worth stating is the shape of the improvement. For small γ, $T_{k-1}(1+2\gamma)$ grows roughly like $(1+2\sqrt{\gamma})^{k-1}$, where Step 3 managed only $(1+2\gamma)^{k-1}$. A small gap costs a square root, not a full factor. That is the same square root that the next section extracts for conjugate gradients, and it is the reason Krylov methods are used at all.

23.6.6 Losing orthogonality

Everything above is exact arithmetic. In the floating-point model of Definition 23.1.1, one feature of the Lanczos recurrence fails, and it fails in a way that is worth describing honestly rather than proving badly.

The three-term recurrence never re-examines $\mathbf{q}_1, \ldots, \mathbf{q}_{j-2}$. In exact arithmetic it does not need to: Theorem 23.6.3 proves that $\mathbf{w}_j$ is automatically orthogonal to them. In floating-point arithmetic the computed vectors satisfy the recurrence to within a small multiple of $u\|\mathbf{A}\|$, and nothing removes the small components along the earlier vectors that rounding introduces. Those components do not stay small.

The mechanism is specific, and it is not random drift. The component of the computed $\mathbf{q}_{k+1}$ along a Ritz vector $\mathbf{x}$ grows in inverse proportion to that Ritz pair's residual $\beta_k |y_k|$. So orthogonality is lost first, and most, in exactly the direction of a Ritz pair that has **converged** — the better the approximation, the faster the basis is corrupted in its direction. The visible symptom

is that the computed $\mathbf{T}_k$ acquires a second copy of a Ritz value that converged several steps earlier, and later a third: the spurious duplicates, which correspond to no extra multiplicity in $\mathbf{A}$. An algorithm that counts eigenvalues by counting Ritz values will count wrong.

This paragraph is a description of observed behavior, not a theorem, and this book does not prove it. The analysis that makes it precise — that the loss of orthogonality is confined to the converged directions, and that the computed $\mathbf{T}_k$ is the exact tridiagonal matrix of a larger problem — is due to Paige, and it is outside the scope of this chapter. Nothing above depends on it. The standard remedies are to reorthogonalize each new vector against all the earlier ones, which restores the guarantee and abandons the three-term economy, or to reorthogonalize only against the converged Ritz vectors, which is cheaper and rests on precisely the analysis we are not giving. Both are engineering, not theorems, and we label them as such.

23.6.7 Exercises

23.6.7.1 A. Check your understanding

Exercise A1.

(a) Define $\mathcal{K}_k(\mathbf{A}, \mathbf{b})$ and state its dimension in terms of $m_{\mathbf{A},\mathbf{b}}$.

(b) State the Arnoldi identity of Theorem 23.6.2 (b), naming the shape of every matrix in it.

(c) True or false: for Hermitian $\mathbf{A}$, the Arnoldi process needs all of $\mathbf{q}_1, \dots, \mathbf{q}_j$ to produce $\mathbf{q}_{j+1}$. Justify your answer.

(d) What does a breakdown $h_{k+1,k} = 0$ mean, and why is it good news?

(e) Give the formula for the residual of a Ritz pair, and say why it costs nothing to evaluate.

Solution.

(a) $\mathcal{K}_k(\mathbf{A}, \mathbf{b}) = \operatorname{span}(\mathbf{b}, \mathbf{A}\mathbf{b}, \dots, \mathbf{A}^{k-1}\mathbf{b})$, and $\dim \mathcal{K}_k = \min(k, d)$ with $d = \deg m_{\mathbf{A},\mathbf{b}}$ (Proposition 23.6.1).

(b) $\mathbf{A}\mathbf{Q}_k = \mathbf{Q}_{k+1}\widetilde{\mathbf{H}}_k$, where $\mathbf{Q}_k \in M_{n\times k}$ and $\mathbf{Q}_{k+1} \in M_{n\times(k+1)}$ have orthonormal columns and $\widetilde{\mathbf{H}}_k \in M_{(k+1)\times k}$ is upper Hessenberg; equivalently $\mathbf{A}\mathbf{Q}_k = \mathbf{Q}_k\mathbf{H}_k + h_{k+1,k}\mathbf{q}_{k+1}\mathbf{e}_k^\top$ with $\mathbf{H}_k = \mathbf{Q}_k^*\mathbf{A}\mathbf{Q}_k \in M_k$ upper Hessenberg.

(c) False. By Theorem 23.6.3 the recurrence has three terms, so only $\mathbf{q}_{j-1}$ and $\mathbf{q}_j$ are needed. The reason is that $\mathbf{H}_k$ is both Hermitian and upper Hessenberg, hence tridiagonal.

(d) It means $\mathcal{K}_k$ is $\mathbf{A}$-invariant (Theorem 23.6.2 (c)), equivalently $k = d$. It is good news because every eigenvalue of $\mathbf{H}_k$ is then an exact eigenvalue of $\mathbf{A}$: the method has finished, not failed.

(e) $\|\mathbf{A}\mathbf{x} - \theta\mathbf{x}\| = h_{k+1,k}|y_k|$ (Theorem 23.6.4 (b)). Both factors are already known — $h_{k+1,k}$ from the last step of the process, y_k from the small eigenvector — so no multiplication by $\mathbf{A}$ is needed.

23.6.7.2 B. Practice

Exercise B1: Dimensions.

For each pair $(\mathbf{A}, \mathbf{b})$, determine $\dim \mathcal{K}_k(\mathbf{A}, \mathbf{b})$ for every $k \geq 1$. Justify your answer.

(a) $\mathbf{A} = \operatorname{diag}(2, 2, 5)$, $\mathbf{b} = (1, 1, 1)$.

(b) $\mathbf{A} = \operatorname{diag}(2, 2, 5)$, $\mathbf{b} = (1, -1, 0)$.

(c) $\mathbf{A} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $\mathbf{b} = \mathbf{e}_2$.

(d) $\mathbf{A}$ the 4×4 matrix with $\mathbf{A}\mathbf{e}_j = \mathbf{e}_{j+1}$ for $j \leq 3$ and $\mathbf{A}\mathbf{e}_4 = \mathbf{0}$, $\mathbf{b} = \mathbf{e}_1$.

Solution. By Proposition 23.6.1 (b) the answer is always $\min(k, d)$ with $d = \deg m_{\mathbf{A},\mathbf{b}}$.

(a) $\mathbf{b}$ has non-zero components in both eigenspaces, so no single factor of $(x-2)(x-5)$ kills it, while the product does: $d = 2$, and the dimensions are $1, 2, 2, 2, \ldots$.

(b) $\mathbf{A}\mathbf{b} = (2, -2, 0) = 2\mathbf{b}$, so $\mathbf{b}$ is an eigenvector and $m_{\mathbf{A},\mathbf{b}} = x - 2$, $d = 1$. The dimensions are $1, 1, 1, \ldots$: every further product is wasted.

(c) $\mathbf{A}\mathbf{e}_2 = \mathbf{e}_1 \neq \mathbf{0}$ and $\mathbf{A}^2\mathbf{e}_2 = \mathbf{0}$, so $m_{\mathbf{A},\mathbf{e}_2} = x^2$ and $d = 2$: dimensions $1, 2, 2, \ldots$.

(d) $\mathbf{A}^j\mathbf{e}_1 = \mathbf{e}_{j+1}$ for $j \leq 3$ and $\mathbf{A}^4\mathbf{e}_1 = \mathbf{0}$, so $m_{\mathbf{A},\mathbf{e}_1} = x^4$ and $d = 4$: dimensions $1, 2, 3, 4, 4, \ldots$. Here the Krylov spaces grow as long as they possibly can.

Exercise B2: Two Arnoldi steps.

Let

$$\mathbf{A} = \begin{pmatrix} 2 & 1 & 1 \\ 0 & 2 & 1 \\ 0 & 0 & 1 \end{pmatrix}, \qquad \mathbf{b} = \mathbf{e}_3.$$

Carry out two Arnoldi steps. Write down $\mathbf{Q}_2$, $\widetilde{\mathbf{H}}_2$ and $\mathbf{H}_2$, verify Eq. 23.6.1, and compute the two Ritz values with their residuals. Hence say which, if either, is a converged eigenvalue estimate.

Solution. $\mathbf{q}_1 = \mathbf{e}_3$ and $\mathbf{A}\mathbf{q}_1 = (1, 1, 1)$, so $h_{11} = \langle \mathbf{A}\mathbf{q}_1, \mathbf{q}_1 \rangle = 1$ and

$$\mathbf{w}_1 = (1, 1, 1) - (0, 0, 1) = (1, 1, 0), \qquad h_{21} = \sqrt{2}, \qquad \mathbf{q}_2 = \tfrac{1}{\sqrt{2}}(1, 1, 0).$$

Next $\mathbf{A}\mathbf{q}_2 = \frac{1}{\sqrt{2}}(3, 2, 0)$, so $h_{12} = \langle \mathbf{A}\mathbf{q}_2, \mathbf{q}_1 \rangle = 0$ and $h_{22} = \frac{1}{2}(3 + 2) = \frac{5}{2}$, and

$$\mathbf{w}_2 = \tfrac{1}{\sqrt{2}}(3, 2, 0) - \tfrac{5}{2} \cdot \tfrac{1}{\sqrt{2}}(1, 1, 0) = \tfrac{1}{2\sqrt{2}}(1, -1, 0), \qquad h_{32} = \tfrac{1}{2},$$

with $\mathbf{q}_3 = \frac{1}{\sqrt{2}}(1, -1, 0)$. Hence

$$\mathbf{Q}_2 = \begin{pmatrix} 0 & \frac{1}{\sqrt{2}} \\ 0 & \frac{1}{\sqrt{2}} \\ 1 & 0 \end{pmatrix}, \qquad \widetilde{\mathbf{H}}_2 = \begin{pmatrix} 1 & 0 \\ \sqrt{2} & \frac{5}{2} \\ 0 & \frac{1}{2} \end{pmatrix}, \qquad \mathbf{H}_2 = \begin{pmatrix} 1 & 0 \\ \sqrt{2} & \frac{5}{2} \end{pmatrix}.$$

Check Eq. 23.6.1 column by column: $\mathbf{A}\mathbf{q}_1 = (1, 1, 1) = 1 \cdot \mathbf{q}_1 + \sqrt{2}\,\mathbf{q}_2$, and $\mathbf{A}\mathbf{q}_2 = \frac{1}{\sqrt{2}}(3, 2, 0) = 0 \cdot \mathbf{q}_1 + \frac{5}{2}\mathbf{q}_2 + \frac{1}{2}\mathbf{q}_3$, both correct.

$\mathbf{H}_2$ is lower triangular as well as upper Hessenberg, so its eigenvalues are $\theta = 1$ and $\theta = \frac{5}{2}$. For $\theta = \frac{5}{2}$: solving $\mathbf{H}_2\mathbf{y} = \frac{5}{2}\mathbf{y}$ gives $y_1 = 0$, so $\mathbf{y} = (0, 1)$, $y_2 = 1$, and the residual is $h_{32}|y_2| = \frac{1}{2}$. For $\theta = 1$: $\sqrt{2}\,y_1 + \frac{3}{2}y_2 = 0$, so $\mathbf{y} = \frac{1}{\sqrt{17}}(3, -2\sqrt{2})$ and the residual is $\frac{1}{2} \cdot \frac{2\sqrt{2}}{\sqrt{17}} = \frac{\sqrt{34}}{17} \approx 0.343$.

Neither is converged. The eigenvalues of $\mathbf{A}$ are $2, 2, 1$, so the Ritz value 1 is exactly an eigenvalue — yet its residual is 0.343, not 0, and its Ritz vector $\mathbf{Q}_2\mathbf{y} = \frac{1}{\sqrt{17}}(-2, -2, 3)$ is not an eigenvector: the eigenvectors for 1 are the multiples of $(0, 1, -1)$, which is not in $\mathcal{K}_2 = \operatorname{span}(\mathbf{e}_3, (1, 1, 0))$. The agreement is a coincidence of two numbers, and the residual is what says so.

Exercise B3: Lanczos on a tridiagonal matrix.

Let $\mathbf{A} \in M_n(\mathbb{R})$ be symmetric tridiagonal with every subdiagonal entry non-zero, and let $\mathbf{b} = \mathbf{e}_1$. Prove that the Lanczos process produces $\mathbf{q}_j = \pm\mathbf{e}_j$ for every j, and hence that $\mathbf{T}_n = \mathbf{A}$ up to signs. What does this say about the cost of Lanczos on a matrix that is already tridiagonal?

Solution. We show by induction on j that

$$\mathbf{A}^j\mathbf{e}_1 = \sum_{i \le j+1} c_i^{(j)}\mathbf{e}_i \qquad \text{with} \qquad c_{j+1}^{(j)} = a_{21}a_{32}\cdots a_{j+1,j} \neq 0,$$

for $0 \le j \le n-1$. At $j = 0$ the sum is $\mathbf{e}_1$ and the coefficient is the empty product 1. Suppose it holds at $j-1$. Since $\mathbf{A}$ is tridiagonal, $\mathbf{A}\mathbf{e}_i \in \operatorname{span}(\mathbf{e}_{i-1}, \mathbf{e}_i, \mathbf{e}_{i+1})$, so applying $\mathbf{A}$ to $\mathbf{A}^{j-1}\mathbf{e}_1 = \sum_{i \le j} c_i^{(j-1)}\mathbf{e}_i$ lands in $\operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_{j+1})$; and the only term contributing to $\mathbf{e}_{j+1}$ is $c_j^{(j-1)}\mathbf{A}\mathbf{e}_j$, whose $\mathbf{e}_{j+1}$-coefficient is $c_j^{(j-1)}a_{j+1,j} \neq 0$, both factors being non-zero. This proves the induction.

Consequently the change-of-basis matrix from $(\mathbf{e}_1, \dots, \mathbf{e}_j)$ to $(\mathbf{e}_1, \mathbf{A}\mathbf{e}_1, \dots, \mathbf{A}^{j-1}\mathbf{e}_1)$ is triangular with non-zero diagonal, so $\mathcal{K}_j(\mathbf{A}, \mathbf{e}_1) = \operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_j)$ for $1 \le j \le n$.

By Theorem 23.6.2 (a), $\mathbf{q}_j$ is a unit vector in $\mathcal{K}_j$ orthogonal to $\mathcal{K}_{j-1} = \operatorname{span}(\mathbf{e}_1, \dots, \mathbf{e}_{j-1})$, hence a unit multiple of $\mathbf{e}_j$; the sign is fixed by $\beta_{j-1} > 0$. Therefore $(\mathbf{T}_n)_{ij} = \langle \mathbf{A}\mathbf{q}_j, \mathbf{q}_i \rangle = \pm a_{ij}$, and since $\mathbf{q}_j = \varepsilon_j\mathbf{e}_j$ with $\varepsilon_j = \pm 1$, $\mathbf{T}_n = \mathbf{D}\mathbf{A}\mathbf{D}$ with $\mathbf{D} = \operatorname{diag}(\varepsilon_1, \dots, \varepsilon_n)$ — a similarity, so the two have the same eigenvalues.

The cost lesson is that Lanczos does no work at all here beyond rediscovering the matrix: on a tridiagonal matrix with $\mathbf{b} = \mathbf{e}_1$ it reproduces $\mathbf{A}$ and finds nothing early. The method earns its keep when n is large and only the first few extreme eigenvalues are wanted, so that $k \ll n$.

23.6.7.3 C. Going deeper

Exercise C1: Ritz values from the other end.

Let $\mathbf{A} \in M_n(\mathbb{C})$ be Hermitian and let $\theta_1^{(k)} \ge \cdots \ge \theta_k^{(k)}$ be the Ritz values from $\mathcal{K}_k(\mathbf{A}, \mathbf{b})$, $1 \le k \le d$.

(a) Prove that $\theta_k^{(k)}$ is non-increasing in k and that $\theta_k^{(k)} \ge \lambda_n(\mathbf{A})$.

(b) Deduce a bound for $\theta_k^{(k)} - \lambda_n(\mathbf{A})$ from Theorem 23.6.5, with no new argument.

(c) Show that at $k = d$ the Ritz values are d of the eigenvalues of $\mathbf{A}$, and say which.

Solution.

(a) The argument of Step 1 in the proof of Theorem 23.6.5 applies verbatim with minima in place of maxima, using the second half of Proposition 16.1.1: $\theta_k^{(k)} = \min\{R_{\mathbf{A}}(\mathbf{x}) : \mathbf{x} \in \mathcal{K}_k,\ \mathbf{x} \neq \mathbf{0}\}$. A minimum over a larger set is no larger, and $\mathcal{K}_k \subseteq \mathcal{K}_{k+1}$, so the sequence is non-increasing; and the minimum over all of $\mathbb{C}^n$ is $\lambda_n(\mathbf{A})$, so it is bounded below by that. (Alternatively, both statements are Theorem 23.6.4 (a) at $i = k$.)

(b) Apply Theorem 23.6.5 to $-\mathbf{A}$. Its eigenvalues are $-\lambda_n \geq -\lambda_{n-1} \geq \cdots \geq -\lambda_1$, with the same orthonormal eigenbasis in reversed order. Its Krylov spaces from $\mathbf{b}$ are the same subspaces, because $(-\mathbf{A})^j\mathbf{b} = (-1)^j\mathbf{A}^j\mathbf{b}$ and scaling the vectors of a list does not change its span. And $R_{-\mathbf{A}} = -R_{\mathbf{A}}$, so by Step 1 of the proof the largest Ritz value of $-\mathbf{A}$ from $\mathcal{K}_k$ is $-\theta_k^{(k)}$. The theorem gives

$$\theta_k^{(k)} - \lambda_n \leq (\lambda_1 - \lambda_n)\,\tilde{\tau}^2\,\tilde{\rho}^{\,2(k-1)}, \qquad \tilde{\rho} = \frac{\lambda_1 - \lambda_{n-1}}{\lambda_1 + \lambda_{n-1} - 2\lambda_n},$$

with $\tilde{\tau}^2 = \sum_{i \leq n-1} |c_i|^2/|c_n|^2$, provided $\lambda_{n-1} > \lambda_n$ and $c_n \neq 0$.

(c) At $k = d$ the process breaks down, so $\mathcal{K}_d$ is $\mathbf{A}$-invariant and every Ritz value is an eigenvalue of $\mathbf{A}$ by Theorem 23.6.2 (c). Which ones: writing $\mathbf{b} = \sum_i c_i\mathbf{v}_i$ in an orthonormal eigenbasis and grouping the eigenvectors by eigenvalue, $p(\mathbf{A})\mathbf{b} = \sum_i c_i p(\lambda_i)\mathbf{v}_i$, so $\mathcal{K}_d$ is contained in the span of those $\mathbf{v}_i$ with $c_i \neq 0$. The Ritz values are therefore the distinct eigenvalues λ of $\mathbf{A}$ for which $\mathbf{b}$ has a non-zero component in $E_\lambda(\mathbf{A})$, each occurring once; and d is their number, as Example (A breakdown at step two) illustrates with $d = 2$ for a matrix with eigenvalues $5, 2, 2$.

Exercise C2: Shift invariance, and what it costs.

Let $\mathbf{A} \in M_n(F)$, $\mathbf{b} \neq \mathbf{0}$, and let $\sigma, c \in F$ with $c \neq 0$.

(a) Prove that $\mathcal{K}_k(c\mathbf{A} + \sigma\mathbf{I}, \mathbf{b}) = \mathcal{K}_k(\mathbf{A}, \mathbf{b})$ for every k.

(b) Deduce that the Arnoldi vectors $\mathbf{q}_j$ are the same for $\mathbf{A}$ and for $c\mathbf{A} + \sigma\mathbf{I}$, up to a scalar of modulus one, and that the Ritz values transform by $\theta \mapsto c\theta + \sigma$.

(c) Contrast this with Section 5: explain in two sentences why shifting accelerates the QR algorithm but does **not** accelerate a Krylov method, and what one must do instead to get the effect.

Solution.

(a) Put $\mathbf{B} = c\mathbf{A} + \sigma\mathbf{I}$. By Proposition 23.6.1 (a), $\mathcal{K}_k(\mathbf{B}, \mathbf{b}) = \{p(\mathbf{B})\mathbf{b} : \deg p \leq k-1\}$ and $p(\mathbf{B}) = p(c\mathbf{A}+\sigma\mathbf{I}) = \tilde{p}(\mathbf{A})$ where $\tilde{p}(x) = p(cx+\sigma)$ has the same degree, $c \neq 0$. The map $p \mapsto \tilde{p}$ is a bijection of $F[x]_{\leq k-1}$ onto itself, with inverse $q \mapsto q((x-\sigma)/c)$. So the two sets of vectors coincide.

(b) The Arnoldi vectors are determined by the flag $\mathcal{K}_1 \subseteq \mathcal{K}_2 \subseteq \ldots$ alone, up to a scalar of modulus one: $\mathbf{q}_j$ is a unit vector in $\mathcal{K}_j$ orthogonal to $\mathcal{K}_{j-1}$ (Theorem 23.6.2 (a)), and the unit vectors of $\mathcal{K}_j \cap \mathcal{K}_{j-1}^{\perp}$ are exactly the modulus-one multiples of one

of them. By (a) the flag is the same for $\mathbf{B}$ as for $\mathbf{A}$, so the run on $\mathbf{B}$ produces $\mathbf{Q}_k^{\mathbf{B}} = \mathbf{Q}_k\mathbf{D}$ with $\mathbf{D} = \operatorname{diag}(d_1, \dots, d_k)$ and $|d_j| = 1$. The scalars need not all be 1: each run fixes its own by $h_{j,j-1} > 0$, and for $c = -1$, $\sigma = 0$, $\mathbf{A} = \operatorname{diag}(4, 3, 2, 1)$ and $\mathbf{b} = (1, 1, 1, 1)$ the two runs give $\mathbf{q}_j^{\mathbf{B}} = (-1)^{j-1}\mathbf{q}_j$. Consequently

$$(\mathbf{Q}_k^{\mathbf{B}})^{*}\,\mathbf{B}\,\mathbf{Q}_k^{\mathbf{B}} = \mathbf{D}^{*}\big(c\,\mathbf{Q}_k^{*}\mathbf{A}\mathbf{Q}_k + \sigma\mathbf{Q}_k^{*}\mathbf{Q}_k\big)\mathbf{D} = \mathbf{D}^{*}(c\mathbf{H}_k + \sigma\mathbf{I}_k)\mathbf{D},$$

whose eigenvalues, $\mathbf{D}$ being unitary, are those of $c\mathbf{H}_k + \sigma\mathbf{I}_k$, namely $c\theta_i + \sigma$.

(c) The QR algorithm converges at a rate governed by ratios $|\lambda_{i+1} - \mu|/|\lambda_i - \mu|$, and those ratios genuinely change with μ; a Krylov space does not change at all under a shift, by (a), so nothing it produces can change either. To get the analogous effect one must change the space, not the matrix: apply the method to $(\mathbf{A}-\mu\mathbf{I})^{-1}$, whose Krylov spaces are different, which is the Krylov version of the inverse iteration of Theorem 23.4.3 and costs a factorization of $\mathbf{A} - \mu\mathbf{I}$ rather than a matrix-vector product.

Exercise C3: When the Krylov space is everything.

Let $\mathbf{A} \in M_n(F)$.

(a) Prove that there exists $\mathbf{b}$ with $\mathcal{K}_n(\mathbf{A}, \mathbf{b}) = F^n$ if and only if $m_{\mathbf{A}} = p_{\mathbf{A}}$.

(b) Prove that in that case the Arnoldi process run to $k = n$ produces a unitary $\mathbf{Q}_n$ with $\mathbf{Q}_n^{*}\mathbf{A}\mathbf{Q}_n$ upper Hessenberg, all of whose subdiagonal entries are non-zero.

(c) Hence give a second proof of Theorem 10.8.5 over $\mathbb{C}$ for such $\mathbf{A}$, and explain why it does not replace Chapter 10's.

Hint for (a): Chapter 9 §05 calls such a $\mathbf{b}$ *a cyclic vector.*

Solution.

(a) $\mathcal{K}_n(\mathbf{A}, \mathbf{b}) = F^n$ means $\dim \mathcal{K}_n = n$, which by Proposition 23.6.1 (b) means $\deg m_{\mathbf{A},\mathbf{b}} = n$, that is, $Z(\mathbf{b}; \mathbf{A}) = F^n$ and $\mathbf{b}$ is a cyclic vector for $\mathbf{A}$ (Definition 9.5.4). By Theorem 9.5.6, such a vector exists exactly when $m_{\mathbf{A}} = p_{\mathbf{A}}$.

(b) With $d = n$, Theorem 23.6.2 (a) says that $h_{j+1,j} \neq 0$ for every $j < n$ and that $(\mathbf{q}_1, \dots, \mathbf{q}_n)$ is an orthonormal basis of F^n; so $\mathbf{Q}_n$ is unitary, and $\mathbf{Q}_n^{*}\mathbf{A}\mathbf{Q}_n = \mathbf{H}_n$ is upper Hessenberg by Theorem 23.6.2 (b). Its subdiagonal entries are the $h_{j+1,j}$, all non-zero. (A Hessenberg matrix with this property is called **unreduced**, and Proposition 23.5.5 is about exactly these.)

(c) Part (b) exhibits a unitary $\mathbf{Q}_n$ with $\mathbf{Q}_n^{*}\mathbf{A}\mathbf{Q}_n$ upper Hessenberg, which is the conclusion of Theorem 10.8.5. It does not replace that theorem for two reasons. First, it needs $m_{\mathbf{A}} = p_{\mathbf{A}}$ by (a), while Theorem 10.8.5 holds for every square matrix; when no cyclic vector exists, the process breaks down at some $d < n$ and delivers an invariant subspace instead of a full basis. Second, Theorem 10.8.5 is proved by reflections, each applied to the whole matrix, and its $O(n^3)$ cost is what Section 5 assumed; the Arnoldi route needs n matrix-vector products and $O(n^3)$ orthogonalization work as well, and in floating-point arithmetic the orthogonality it produces is exactly what the last subsection says can be lost. The two constructions agree in exact arithmetic when both apply, and the reflection route is the one that is run.

23.7 Steepest Descent and Conjugate Gradients

Section 2 solved $\mathbf{Ax} = \mathbf{b}$ by elimination: about $\frac{2}{3}n^3$ operations, an exact answer after finitely many of them, and a factorization that fills in most of the zeros the matrix had. For a large sparse matrix that is the wrong bargain. This section builds two iterations that touch $\mathbf{A}$ only through the product $\mathbf{x} \mapsto \mathbf{Ax}$, for the case where $\mathbf{A}$ is positive definite, and counts what each of them buys. The first costs about κ steps per decimal digit of accuracy, the second about $\sqrt{\kappa}$. Where that square root comes from is the point of the section.

Throughout, $\mathbf{A} \in M_n(\mathbb{R})$ is symmetric and positive definite, $\mathbf{b} \in \mathbb{R}^n$, and $\mathbf{x}^\star = \mathbf{A}^{-1}\mathbf{b}$ is the exact solution. Iteration indices are superscripts in parentheses. We work over $\mathbb{R}$ because the function this section minimizes is built from $\mathbf{b}^\top\mathbf{x}$, which over $\mathbb{C}$ is not a real number; everything below survives over $\mathbb{C}$ with $\mathbf{b}^*\mathbf{x}$ replaced by its real part, and nothing else changes.

23.7.1 A linear system is a minimization problem

Positive definiteness is a statement about the number $\mathbf{x}^\top\mathbf{Ax}$ (Definition 12.1.1), so it invites us to look for a *quantity* that the solution makes small, rather than an equation the solution satisfies. There is one, and it is the simplest possible candidate: a quadratic minus a linear term.

Solving $\mathbf{Ax} = \mathbf{b}$ is the same as sitting at the bottom of a bowl.

Definition 23.7.1 — The Energy Inner Product and the Energy Norm

Let $\mathbf{A} \in M_n(\mathbb{R})$ be symmetric positive definite. The **energy inner product** is

$$\langle \mathbf{x}, \mathbf{y} \rangle_{\mathbf{A}} \coloneqq \mathbf{y}^\top \mathbf{Ax} \qquad (\mathbf{x}, \mathbf{y} \in \mathbb{R}^n),$$

and the **energy norm** is $\|\mathbf{x}\|_{\mathbf{A}} \coloneqq \langle \mathbf{x}, \mathbf{x} \rangle_{\mathbf{A}}^{1/2} = (\mathbf{x}^\top\mathbf{Ax})^{1/2}$. Two vectors are **A-orthogonal**, or **conjugate**, when $\langle \mathbf{x}, \mathbf{y} \rangle_{\mathbf{A}} = 0$.

This is the inner product of Chapter 12 §04, written there as $\mathbf{y}^*\mathbf{Ax}$. It really is one: it is bilinear because matrix multiplication is; it is symmetric because the 1×1 matrix $\mathbf{y}^\top\mathbf{Ax}$ equals its own transpose $\mathbf{x}^\top\mathbf{Ay}$; and $\langle \mathbf{x}, \mathbf{x} \rangle_{\mathbf{A}} > 0$ for $\mathbf{x} \neq \mathbf{0}$ is clause (P2) of Definition 12.1.1 in its strict form. So $\|\cdot\|_{\mathbf{A}}$ is the induced norm of Definition 10.1.3, and every fact about norms and orthogonality from Chapter 10 applies verbatim. That is the reason for introducing it: it lets us reuse the Pythagorean theorem in a geometry bent by $\mathbf{A}$.

The word *energy* comes from the springs of Section 9, where $\frac{1}{2}\mathbf{x}^\top\mathbf{Kx}$ is the potential energy stored in a displacement $\mathbf{x}$.

Proposition 23.7.1 — The Solution Minimizes the Energy Functional

Let $\mathbf{A} \in M_n(\mathbb{R})$ be symmetric positive definite, $\mathbf{b} \in \mathbb{R}^n$, and define

$$\phi(\mathbf{x}) := \tfrac{1}{2}\,\mathbf{x}^\top \mathbf{A}\mathbf{x} - \mathbf{b}^\top \mathbf{x} \qquad (\mathbf{x} \in \mathbb{R}^n).$$

Then, with $\mathbf{x}^\star = \mathbf{A}^{-1}\mathbf{b}$,

$$\phi(\mathbf{x}) - \phi(\mathbf{x}^\star) = \tfrac{1}{2}\|\mathbf{x} - \mathbf{x}^\star\|_{\mathbf{A}}^2 \qquad \text{for every } \mathbf{x} \in \mathbb{R}^n.$$

In particular $\mathbf{x}^\star$ is the **unique** minimizer of ϕ.

Proof. $\mathbf{A}$ is invertible, since $\mathbf{A} \succ 0$ has only positive eigenvalues (Theorem 12.1.5, (a) $\Rightarrow$ (b)), so $\mathbf{x}^\star$ is defined and $\mathbf{A}\mathbf{x}^\star = \mathbf{b}$. Expand, using $\mathbf{A}^\top = \mathbf{A}$:

$$\begin{aligned} \tfrac{1}{2}\|\mathbf{x} - \mathbf{x}^\star\|_{\mathbf{A}}^2 &= \tfrac{1}{2}\mathbf{x}^\top \mathbf{A}\mathbf{x} - \mathbf{x}^\top \mathbf{A}\mathbf{x}^\star + \tfrac{1}{2}(\mathbf{x}^\star)^\top \mathbf{A}\mathbf{x}^\star \\ &= \tfrac{1}{2}\mathbf{x}^\top \mathbf{A}\mathbf{x} - \mathbf{b}^\top \mathbf{x} + \tfrac{1}{2}\,\mathbf{b}^\top \mathbf{x}^\star, \end{aligned}$$

where the second line uses $\mathbf{A}\mathbf{x}^\star = \mathbf{b}$ twice and $\mathbf{x}^\top \mathbf{b} = \mathbf{b}^\top \mathbf{x}$. The first two terms are $\phi(\mathbf{x})$. Putting $\mathbf{x} = \mathbf{x}^\star$ gives $0 = \phi(\mathbf{x}^\star) + \tfrac{1}{2}\mathbf{b}^\top \mathbf{x}^\star$, so the leftover constant is $-\phi(\mathbf{x}^\star)$, which is the identity. Since $\|\cdot\|_{\mathbf{A}}$ is a norm, the right-hand side is ≥ 0 with equality only at $\mathbf{x} = \mathbf{x}^\star$. This proves the proposition. ∎

So every iteration below may be read twice: as an attempt to solve a linear system, and as an attempt to walk downhill on a bowl whose shape is $\mathbf{A}$. The identity also tells us which error to measure. The natural yardstick is not $\|\mathbf{x} - \mathbf{x}^\star\|_2$ but $\|\mathbf{x} - \mathbf{x}^\star\|_{\mathbf{A}}$, because that is the one the algorithms actually make small.

Two quantities recur. The **error** is $\boldsymbol{\varepsilon} = \mathbf{x} - \mathbf{x}^\star$ and the **residual** is $\mathbf{r} = \mathbf{b} - \mathbf{A}\mathbf{x}$, and they are related by

$$\mathbf{r} = \mathbf{b} - \mathbf{A}\mathbf{x} = \mathbf{A}\mathbf{x}^\star - \mathbf{A}\mathbf{x} = -\mathbf{A}\boldsymbol{\varepsilon}. \tag{23.7.1}$$

The residual is computable and the error is not; Eq. 23.7.1 is the exchange rate between them.

23.7.2 Steepest descent

Fix $\mathbf{x}$ and a direction $\mathbf{d} \neq \mathbf{0}$, and ask what happens along the line $\mathbf{x} + t\mathbf{d}$. Expanding ϕ and using $\mathbf{A}^\top = \mathbf{A}$,

$$\phi(\mathbf{x} + t\mathbf{d}) = \phi(\mathbf{x}) - t\,\mathbf{d}^\top \mathbf{r} + \tfrac{1}{2}t^2\,\mathbf{d}^\top \mathbf{A}\mathbf{d}, \tag{23.7.2}$$

where $\mathbf{r} = \mathbf{b} - \mathbf{A}\mathbf{x}$. Since $\mathbf{d}^\top \mathbf{A}\mathbf{d} > 0$, the right-hand side is a parabola in t opening upwards, so it has one minimum, at

$$t = \frac{\mathbf{d}^\top \mathbf{r}}{\mathbf{d}^\top \mathbf{A}\mathbf{d}}, \qquad \text{with decrease} \quad \frac{(\mathbf{d}^\top \mathbf{r})^2}{2\,\mathbf{d}^\top \mathbf{A}\mathbf{d}}. \tag{23.7.3}$$

Choosing t this way is an **exact line search**; it costs one product $\mathbf{A}\mathbf{d}$.

Which $\mathbf{d}$ should we take? Read Eq. 23.7.2 for small t: the decrease is $t\,\mathbf{d}^\top\mathbf{r}$ to first order, and among unit vectors $\mathbf{d}$ the quantity $\mathbf{d}^\top\mathbf{r}$ is largest exactly at $\mathbf{d} = \mathbf{r}/\|\mathbf{r}\|_2$, by Cauchy–Schwarz (Theorem 10.1.5) with its equality case. So the residual is the direction in which ϕ falls fastest *at the starting point*, measured in the ordinary Euclidean norm.

> *Warning.* **"Steepest" is a statement about the first instant, not about the step.** The direction that minimizes ϕ over the whole line is not $\mathbf{r}$ but $\mathbf{A}^{-1}\mathbf{r}$: with $\mathbf{d} = \mathbf{A}^{-1}\mathbf{r}$, Eq. 23.7.3 gives $t = 1$ and $\mathbf{x} + \mathbf{d} = \mathbf{x} + \mathbf{A}^{-1}(\mathbf{b} - \mathbf{A}\mathbf{x}) = \mathbf{x}^\star$, the exact answer in one step. That direction is unavailable, because producing it means solving the very system we are trying to solve. Every method in this section is an attempt to approximate $\mathbf{A}^{-1}\mathbf{r}$ cheaply.

Definition 23.7.2 — Steepest Descent

Let $\mathbf{A} \succ 0$ and $\mathbf{b} \in \mathbb{R}^n$, and let $\mathbf{x}^{(0)} \in \mathbb{R}^n$. **Steepest descent** is the iteration: for $k = 0, 1, 2, \ldots$, set $\mathbf{r}^{(k)} = \mathbf{b} - \mathbf{A}\mathbf{x}^{(k)}$; if $\mathbf{r}^{(k)} = \mathbf{0}$, stop, since $\mathbf{x}^{(k)} = \mathbf{x}^\star$; otherwise put

$$t_k = \frac{(\mathbf{r}^{(k)})^\top \mathbf{r}^{(k)}}{(\mathbf{r}^{(k)})^\top \mathbf{A}\mathbf{r}^{(k)}}, \qquad \mathbf{x}^{(k+1)} = \mathbf{x}^{(k)} + t_k\,\mathbf{r}^{(k)}.$$

The denominator is positive because $\mathbf{r}^{(k)} \neq \mathbf{0}$ and $\mathbf{A} \succ 0$, so t_k is defined, and $t_k > 0$. One step costs one matrix–vector product.

To see how fast this is we need one inequality, and it is a statement about weighted averages, not about matrices at all.

Lemma 23.7.2 — Kantorovich's Inequality

Let $\mathbf{A} \in M_n(\mathbb{R})$ be symmetric positive definite with eigenvalues $\lambda_1 \geq \cdots \geq \lambda_n > 0$. Then for every $\mathbf{y} \in \mathbb{R}^n$,

$$(\mathbf{y}^\top\mathbf{A}\mathbf{y})(\mathbf{y}^\top\mathbf{A}^{-1}\mathbf{y}) \leq \frac{(\lambda_1 + \lambda_n)^2}{4\lambda_1\lambda_n}\,(\mathbf{y}^\top\mathbf{y})^2.$$

Idea. In an orthonormal eigenbasis both factors become weighted averages of the eigenvalues, one of λ and one of $1/\lambda$, with the same weights. The obstacle is that $1/\lambda$ is not linear, so the second average is not determined by the first. It is, however, *bounded* by it: on the interval $[\lambda_n, \lambda_1]$ the curve $1/\lambda$ lies below the straight line joining its endpoints. Replacing the curve by that line makes the second average a linear function of the first, and the product becomes a scalar quadratic that we maximize by hand.

Proof. Write $a = \lambda_1$ and $c = \lambda_n$. For every λ with $c \leq \lambda \leq a$,

$$\frac{a + c - \lambda}{ac} - \frac{1}{\lambda} = \frac{\lambda(a + c - \lambda) - ac}{ac\lambda} = \frac{-(\lambda - a)(\lambda - c)}{ac\lambda} \;\geq\; 0, \tag{$*$}$$

because $\lambda - a \leq 0$, $\lambda - c \geq 0$ and $ac\lambda > 0$.

We may assume $\mathbf{y} \neq \mathbf{0}$, the case $\mathbf{y} = \mathbf{0}$ being an equality $0 = 0$, and by homogeneity (both sides scale by s^4 under $\mathbf{y} \mapsto s\mathbf{y}$) we may assume $\mathbf{y}^\top\mathbf{y} = 1$. By the spectral theorem (Corollary 11.5.2) there is an orthonormal basis $\mathbf{q}_1, \ldots, \mathbf{q}_n$ of $\mathbb{R}^n$ with $\mathbf{A}\mathbf{q}_i = \lambda_i\mathbf{q}_i$. Let

$u_i = \mathbf{q}_i^{\top}\mathbf{y}$ be the coordinates of $\mathbf{y}$ in that basis, and put $w_i = u_i^2$. Then $\sum_i w_i = \|\mathbf{y}\|_2^2 = 1$ by Parseval's identity (Theorem 10.9.2), every $w_i \geq 0$, and

$$\mathbf{y}^{\top}\mathbf{A}\mathbf{y} = \sum_i \lambda_i w_i =: \mu, \qquad \mathbf{y}^{\top}\mathbf{A}^{-1}\mathbf{y} = \sum_i \frac{w_i}{\lambda_i},$$

the second because $\mathbf{A}^{-1}\mathbf{q}_i = \lambda_i^{-1}\mathbf{q}_i$. Since the w_i are weights summing to 1 and every $\lambda_i \in [c, a]$, the number μ lies in $[c, a]$. Averaging $(*)$ with the weights w_i,

$$\mathbf{y}^{\top}\mathbf{A}^{-1}\mathbf{y} \leq \sum_i w_i \frac{a + c - \lambda_i}{ac} = \frac{a + c - \mu}{ac}.$$

Hence $(\mathbf{y}^{\top}\mathbf{A}\mathbf{y})(\mathbf{y}^{\top}\mathbf{A}^{-1}\mathbf{y}) \leq \mu(a + c - \mu)/(ac)$. Finally, for any real μ,

$$\mu(a + c - \mu) = \frac{(a + c)^2}{4} - \left(\frac{a + c}{2} - \mu\right)^2 \leq \frac{(a + c)^2}{4},$$

and dividing by ac gives the bound. This proves the lemma.

■

Remark. Equality is attainable: take $\mathbf{y} = (\mathbf{q}_1 + \mathbf{q}_n)/\sqrt{2}$, so that $w_1 = w_n = \frac{1}{2}$ and every other weight is 0. Then $(*)$ is an equality at each λ_i carrying weight, since those are a and c, and $\mu = (a + c)/2$ makes the last step an equality too. Only the weights $w_i = u_i^2$ enter, so $(\mathbf{q}_1 - \mathbf{q}_n)/\sqrt{2}$ serves just as well, and so does any non-zero multiple of either. Example (The bound is attained) does exactly this, up to sign and scale.

We also record the condition number in the form we shall use it. For $\mathbf{A} \succ 0$, Lemma 16.3.5 gives $\|\mathbf{A}\|_2 = \lambda_1$, since all eigenvalues are positive; the eigenvalues of $\mathbf{A}^{-1}$ are the λ_i^{-1}, so the same lemma gives $\|\mathbf{A}^{-1}\|_2 = \lambda_n^{-1}$. Hence, by Definition 15.8.1,

$$\kappa := \kappa_2(\mathbf{A}) = \frac{\lambda_1}{\lambda_n} \geq 1. \tag{23.7.4}$$

Theorem 23.7.3 — Convergence of Steepest Descent

Let $\mathbf{A} \in M_n(\mathbb{R})$ be symmetric positive definite with $\kappa = \kappa_2(\mathbf{A})$, let $\mathbf{b} \in \mathbb{R}^n$, and let $\mathbf{x}^{(0)}, \mathbf{x}^{(1)}, \ldots$ be the steepest descent iterates. Then for every k for which $\mathbf{x}^{(k)}$ is defined,

$$\|\mathbf{x}^{(k)} - \mathbf{x}^{\star}\|_{\mathbf{A}} \leq \left(\frac{\kappa - 1}{\kappa + 1}\right)^k \|\mathbf{x}^{(0)} - \mathbf{x}^{\star}\|_{\mathbf{A}}.$$

Idea. One step at a time. Write the new energy-norm error in terms of the old one; the exact line search makes the difference a single explicit fraction, whose numerator and denominator are exactly the three quantities Kantorovich's inequality compares. What comes out is $1 - 4\lambda_1\lambda_n/(\lambda_1 + \lambda_n)^2$, and that number is the square of $(\kappa - 1)/(\kappa + 1)$.

Proof. It is enough to prove the estimate for one step and then iterate. Fix k and write $\mathbf{x} = \mathbf{x}^{(k)}$, $\mathbf{r} = \mathbf{r}^{(k)}$, $t = t_k$ and $\boldsymbol{\varepsilon} = \boldsymbol{\varepsilon}^{(k)} := \mathbf{x}^{(k)} - \mathbf{x}^{\star}$, and assume $\mathbf{r} \neq \mathbf{0}$. By Eq. 23.7.1, $\mathbf{r} = -\mathbf{A}\boldsymbol{\varepsilon}$, so

$$\|\boldsymbol{\varepsilon}\|_{\mathbf{A}}^2 = \boldsymbol{\varepsilon}^{\top}\mathbf{A}\boldsymbol{\varepsilon} = (\mathbf{A}^{-1}\mathbf{r})^{\top}\mathbf{A}(\mathbf{A}^{-1}\mathbf{r}) = \mathbf{r}^{\top}\mathbf{A}^{-1}\mathbf{r},$$

using $\mathbf{A}^\top = \mathbf{A}$ and $(\mathbf{A}^{-1})^\top = \mathbf{A}^{-1}$. The new error is $\boldsymbol{\varepsilon} + t\mathbf{r}$, so

$$\begin{aligned}\|\boldsymbol{\varepsilon} + t\mathbf{r}\|_{\mathbf{A}}^2 &= \|\boldsymbol{\varepsilon}\|_{\mathbf{A}}^2 + 2t\,\mathbf{r}^\top\mathbf{A}\boldsymbol{\varepsilon} + t^2\,\mathbf{r}^\top\mathbf{A}\mathbf{r} \\ &= \|\boldsymbol{\varepsilon}\|_{\mathbf{A}}^2 - 2t\,\mathbf{r}^\top\mathbf{r} + t^2\,\mathbf{r}^\top\mathbf{A}\mathbf{r},\end{aligned}$$

the second line because $\mathbf{A}\boldsymbol{\varepsilon} = -\mathbf{r}$. Substituting $t = (\mathbf{r}^\top\mathbf{r})/(\mathbf{r}^\top\mathbf{A}\mathbf{r})$ collapses the last two terms:

$$\|\boldsymbol{\varepsilon} + t\mathbf{r}\|_{\mathbf{A}}^2 = \|\boldsymbol{\varepsilon}\|_{\mathbf{A}}^2 - \frac{(\mathbf{r}^\top\mathbf{r})^2}{\mathbf{r}^\top\mathbf{A}\mathbf{r}} = \|\boldsymbol{\varepsilon}\|_{\mathbf{A}}^2\Big(1 - \frac{(\mathbf{r}^\top\mathbf{r})^2}{(\mathbf{r}^\top\mathbf{A}\mathbf{r})(\mathbf{r}^\top\mathbf{A}^{-1}\mathbf{r})}\Big),$$

where the last step divides and multiplies by $\|\boldsymbol{\varepsilon}\|_{\mathbf{A}}^2 = \mathbf{r}^\top\mathbf{A}^{-1}\mathbf{r}$, which is non-zero because $\mathbf{r} \neq \mathbf{0}$. By Lemma 23.7.2 applied to $\mathbf{y} = \mathbf{r}$,

$$\frac{(\mathbf{r}^\top\mathbf{r})^2}{(\mathbf{r}^\top\mathbf{A}\mathbf{r})(\mathbf{r}^\top\mathbf{A}^{-1}\mathbf{r})} \;\geq\; \frac{4\lambda_1\lambda_n}{(\lambda_1+\lambda_n)^2},$$

so the bracket is at most

$$1 - \frac{4\lambda_1\lambda_n}{(\lambda_1+\lambda_n)^2} = \frac{(\lambda_1-\lambda_n)^2}{(\lambda_1+\lambda_n)^2} = \Big(\frac{\kappa-1}{\kappa+1}\Big)^2,$$

the last equality on dividing numerator and denominator by λ_n^2 and using Eq. 23.7.4. Since $\boldsymbol{\varepsilon} + t\mathbf{r} = \mathbf{x}^{(k+1)} - \mathbf{x}^\star = \boldsymbol{\varepsilon}^{(k+1)}$, taking square roots gives $\|\boldsymbol{\varepsilon}^{(k+1)}\|_{\mathbf{A}} \leq \frac{\kappa-1}{\kappa+1}\|\boldsymbol{\varepsilon}^{(k)}\|_{\mathbf{A}}$, and an induction on k proves the theorem.

■

Example. (The bound is attained)

Let $\mathbf{A} = \operatorname{diag}(9, 1)$, $\mathbf{b} = (9, 1)$ and $\mathbf{x}^{(0)} = (2, -8)$. Run three steps of steepest descent and compare with Theorem 23.7.3.

Solution. Here $\mathbf{x}^\star = (1, 1)$ and $\kappa = 9$, so the bound's factor is $\frac{4}{5}$. The first residual is

$$\mathbf{r}^{(0)} = \mathbf{b} - \mathbf{A}\mathbf{x}^{(0)} = (9, 1) - (18, -8) = (-9, 9),$$

so $\mathbf{r}^\top\mathbf{r} = 162$ and $\mathbf{r}^\top\mathbf{A}\mathbf{r} = 9\cdot 81 + 81 = 810$, giving $t_0 = \frac{1}{5}$. Then

$$\mathbf{x}^{(1)} = (2, -8) + \tfrac{1}{5}(-9, 9) = \big(\tfrac{1}{5}, -\tfrac{31}{5}\big), \qquad \mathbf{r}^{(1)} = \big(\tfrac{36}{5}, \tfrac{36}{5}\big).$$

The two components of $\mathbf{r}^{(1)}$ are again equal in absolute value, so $t_1 = \frac{1}{5}$ as well, and $\mathbf{x}^{(2)} = \big(\frac{41}{25}, -\frac{119}{25}\big)$, $\mathbf{x}^{(3)} = \big(\frac{61}{125}, -\frac{451}{125}\big)$. The squared energy-norm errors are

$$90, \qquad \tfrac{288}{5}, \qquad \tfrac{4608}{125}, \qquad \tfrac{73728}{3125},$$

and each is exactly $\frac{16}{25}$ times the one before. So the ratio is $\frac{4}{5}$ at every step: the bound of Theorem 23.7.3 holds with equality here, and no better constant is possible.

The picture behind the example is a staircase. On an elongated bowl the steepest direction points across the valley rather than along it, so the iterates cross and re-cross. The residuals $\mathbf{r}^{(0)}$ and $\mathbf{r}^{(2)}$ in Example (The bound is attained) are parallel: the method keeps searching in directions it has already used.

Quick check. Show that consecutive steepest descent residuals are always orthogonal, $(\mathbf{r}^{(k+1)})^{\top}\mathbf{r}^{(k)} = 0$. What does that say about the shape of the path?

Solution. $\mathbf{r}^{(k+1)} = \mathbf{b} - \mathbf{A}\mathbf{x}^{(k+1)} = \mathbf{b} - \mathbf{A}\mathbf{x}^{(k)} - t_k\mathbf{A}\mathbf{r}^{(k)} = \mathbf{r}^{(k)} - t_k\mathbf{A}\mathbf{r}^{(k)}$, so

$$(\mathbf{r}^{(k+1)})^{\top}\mathbf{r}^{(k)} = \mathbf{r}^{\top}\mathbf{r} - t_k\,\mathbf{r}^{\top}\mathbf{A}\mathbf{r} = 0$$

by the choice of t_k, writing $\mathbf{r} = \mathbf{r}^{(k)}$. So each step turns a right angle: the path is a staircase. In two dimensions that forces every second direction to be parallel, which is why Example (The bound is attained) never escapes its worst case.

23.7.3 Conjugate directions

The defect is now visible: each line search spoils the minimality achieved along the previous direction. We want directions $\mathbf{p}^{(0)}, \mathbf{p}^{(1)}, \dots$ for which a search along $\mathbf{p}^{(k)}$ leaves the earlier work intact, so that after k steps the iterate is optimal over the whole k-dimensional affine piece explored so far.

Read the requirement off the goal. Being optimal over $\mathbf{x}^{(0)} + \operatorname{span}(\mathbf{p}^{(0)}, \dots, \mathbf{p}^{(k-1)})$ means, by Proposition 23.7.1, that the error is $\mathbf{A}$-orthogonal to that span; and one step changes the error by $t_k\mathbf{p}^{(k)}$. So the condition that preserves the earlier orthogonality is that $\mathbf{p}^{(k)}$ itself be $\mathbf{A}$-orthogonal to $\mathbf{p}^{(0)}, \dots, \mathbf{p}^{(k-1)}$. That is forced, not guessed. Which conjugate directions? The cheapest answer: take the residual and remove only what $\mathbf{A}$-orthogonality forbids.

Definition 23.7.3 — The Conjugate Gradient Iteration

Let $\mathbf{A} \in M_n(\mathbb{R})$ be symmetric positive definite, $\mathbf{b} \in \mathbb{R}^n$ and $\mathbf{x}^{(0)} \in \mathbb{R}^n$. Set

$$\mathbf{r}^{(0)} = \mathbf{b} - \mathbf{A}\mathbf{x}^{(0)}, \qquad \mathbf{p}^{(0)} = \mathbf{r}^{(0)}.$$

For $k = 0, 1, 2, \dots$: if $\mathbf{r}^{(k)} = \mathbf{0}$, stop. Otherwise put

$$\alpha_k = \frac{(\mathbf{r}^{(k)})^{\top}\mathbf{r}^{(k)}}{(\mathbf{p}^{(k)})^{\top}\mathbf{A}\mathbf{p}^{(k)}}, \qquad \mathbf{x}^{(k+1)} = \mathbf{x}^{(k)} + \alpha_k\mathbf{p}^{(k)},$$

$$\mathbf{r}^{(k+1)} = \mathbf{r}^{(k)} - \alpha_k\mathbf{A}\mathbf{p}^{(k)}, \qquad \beta_k = \frac{(\mathbf{r}^{(k+1)})^{\top}\mathbf{r}^{(k+1)}}{(\mathbf{r}^{(k)})^{\top}\mathbf{r}^{(k)}},$$

and $\mathbf{p}^{(k+1)} = \mathbf{r}^{(k+1)} + \beta_k\mathbf{p}^{(k)}$. This is the **conjugate gradient** iteration, or **CG**.

A non-example, by dropping one clause. Keep everything about the recursion and only weaken $\mathbf{A} \succ 0$ to "symmetric and invertible". Take

$$\mathbf{A} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \qquad \mathbf{b} = (1, 1), \qquad \mathbf{x}^{(0)} = \mathbf{0}.$$

Then $\mathbf{p}^{(0)} = \mathbf{r}^{(0)} = (1, 1)$ and $(\mathbf{p}^{(0)})^{\top}\mathbf{A}\mathbf{p}^{(0)} = 1 - 1 = 0$: the very first α_0 divides by zero, and the iteration does not start. What failed is exactly clause (P2) of Definition 12.1.1 in its strict form, which is what guarantees $\mathbf{p}^{\top}\mathbf{A}\mathbf{p} > 0$ for $\mathbf{p} \neq \mathbf{0}$. Symmetry alone is not enough, and nor is invertibility; both Proposition 23.7.1 (the bowl has a bottom) and Theorem 23.7.4 (the search directions are usable) need definiteness.

Three remarks on the shape of the recursion. The update of $\mathbf{r}$ is not a fresh evaluation of $\mathbf{b}-\mathbf{A}\mathbf{x}$ but a consequence of the update of $\mathbf{x}$; the two agree, since $\mathbf{b}-\mathbf{A}\mathbf{x}^{(k+1)} = \mathbf{r}^{(k)} - \alpha_k \mathbf{A}\mathbf{p}^{(k)}$. Only one product $\mathbf{A}\mathbf{p}^{(k)}$ is formed per step, serving both α_k and $\mathbf{r}^{(k+1)}$. And the new direction corrects the residual by a multiple of the **single** previous direction, not of all of them — the surprise, and the reason CG is short.

Theorem 23.7.4 — Conjugate Gradients: Orthogonality and Optimality

Let $\mathbf{A} \succ 0$, $\mathbf{b} \in \mathbb{R}^n$, $\mathbf{x}^{(0)} \in \mathbb{R}^n$, and write $\mathcal{K}_k = \mathcal{K}_k(\mathbf{A}, \mathbf{r}^{(0)})$ for the Krylov subspaces of Definition 23.6.1, with $\mathcal{K}_0 = \{\mathbf{0}\}$. Suppose the iteration of Definition 23.7.3 has produced non-zero $\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(k)}$. Then:

(a) $\mathbf{p}^{(0)}, \dots, \mathbf{p}^{(k)}$ are non-zero and pairwise $\mathbf{A}$-orthogonal, and every α_j and β_j with $j \le k$ is defined, with $\alpha_j > 0$;
(b) $\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(k)}$ are pairwise orthogonal, and $(\mathbf{r}^{(k+1)})^\top \mathbf{p}^{(j)} = 0$ for every $j \le k$;
(c) $\operatorname{span}(\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(k)}) = \operatorname{span}(\mathbf{p}^{(0)}, \dots, \mathbf{p}^{(k)}) = \mathcal{K}_{k+1}$, a space of dimension $k+1$;
(d) $\mathbf{x}^{(k+1)}$ is the **unique** minimizer of $\|\mathbf{x} - \mathbf{x}^\star\|_{\mathbf{A}}$ over the affine set $\mathbf{x}^{(0)} + \mathcal{K}_{k+1}$.

Idea. Everything is one induction, and the two coefficients are exactly what the induction needs. Step k has to deliver two orthogonality relations: the new residual against the old directions, and the new direction against the old directions in the $\mathbf{A}$-inner product. The first is forced by α_k, the second by β_k, and each forces it only against the *latest* predecessor; the older ones come free, because $\mathbf{A}\mathbf{p}^{(j)}$ is a combination of $\mathbf{r}^{(j)}$ and $\mathbf{r}^{(j+1)}$, and the new residual is already orthogonal to both. Optimality (d) is then the Pythagorean theorem, applied in the energy inner product.

Proof. Parts (a), (b) and (c) are proved together by induction on k. Throughout, $\mathbf{A}^\top = \mathbf{A}$ is used silently to move $\mathbf{A}$ across a dot product, and $\mathbf{A}\mathcal{K}_j \subseteq \mathcal{K}_{j+1}$ directly from Definition 23.6.1.

Base $k = 0$. Here $\mathbf{p}^{(0)} = \mathbf{r}^{(0)} \neq \mathbf{0}$, so $(\mathbf{p}^{(0)})^\top \mathbf{A}\mathbf{p}^{(0)} > 0$ and $\alpha_0 = \|\mathbf{r}^{(0)}\|_2^2 / (\mathbf{p}^{(0)})^\top \mathbf{A}\mathbf{p}^{(0)}$ is defined and positive; that is (a). Part (c) is $\operatorname{span}(\mathbf{r}^{(0)}) = \operatorname{span}(\mathbf{p}^{(0)}) = \mathcal{K}_1$, which is Definition 23.6.1, and the dimension is 1 because $\mathbf{r}^{(0)} \neq \mathbf{0}$. For (b), a single vector is vacuously an orthogonal list, and

$$(\mathbf{r}^{(1)})^\top \mathbf{p}^{(0)} = (\mathbf{r}^{(0)})^\top \mathbf{p}^{(0)} - \alpha_0 (\mathbf{p}^{(0)})^\top \mathbf{A}\mathbf{p}^{(0)} = \|\mathbf{r}^{(0)}\|_2^2 - \|\mathbf{r}^{(0)}\|_2^2 = 0,$$

using $\mathbf{r}^{(1)} = \mathbf{r}^{(0)} - \alpha_0 \mathbf{A}\mathbf{p}^{(0)}$, $\mathbf{p}^{(0)} = \mathbf{r}^{(0)}$ and the definition of α_0.

Inductive step. Assume (a), (b), (c) for k, and assume $\mathbf{r}^{(k+1)} \neq \mathbf{0}$, so that β_k and $\mathbf{p}^{(k+1)}$ are formed. We prove (a), (b), (c) for $k+1$.

Step 1: the residuals stay orthogonal. By (b), $\mathbf{r}^{(k+1)}$ is orthogonal to $\mathbf{p}^{(0)}, \dots, \mathbf{p}^{(k)}$, and by (c) that list spans the same space as $\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(k)}$. Hence $\mathbf{r}^{(k+1)} \perp \mathbf{r}^{(j)}$ for every $j \le k$, and with (b) this makes $\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(k+1)}$ pairwise orthogonal.

Step 2: (c) for $k+1$. From $\mathbf{r}^{(k+1)} = \mathbf{r}^{(k)} - \alpha_k \mathbf{A}\mathbf{p}^{(k)}$ with $\mathbf{r}^{(k)}, \mathbf{p}^{(k)} \in \mathcal{K}_{k+1}$, we get $\mathbf{r}^{(k+1)} \in \mathcal{K}_{k+2}$, and then $\mathbf{p}^{(k+1)} = \mathbf{r}^{(k+1)} + \beta_k \mathbf{p}^{(k)} \in \mathcal{K}_{k+2}$ as well. Moreover

$$\operatorname{span}(\mathbf{p}^{(0)}, \dots, \mathbf{p}^{(k+1)}) = \operatorname{span}(\mathbf{p}^{(0)}, \dots, \mathbf{p}^{(k)}, \mathbf{r}^{(k+1)}) = \operatorname{span}(\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(k+1)}),$$

the first equality because $\mathbf{p}^{(k+1)}$ differs from $\mathbf{r}^{(k+1)}$ by a multiple of $\mathbf{p}^{(k)}$, the second by (c). By Step 1 the vectors $\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(k+1)}$ are non-zero and pairwise orthogonal, hence independent (Theorem 10.1.4), so this common span has dimension $k+2$. It sits inside $\mathcal{K}_{k+2}$, which is spanned by $k+2$ vectors and so has dimension at most $k+2$; equal dimensions force equal spaces.

Step 3: $\mathbf{p}^{(k+1)} \neq \mathbf{0}$, and α_{k+1} is defined. By (b), $(\mathbf{r}^{(k+1)})^\top \mathbf{p}^{(k)} = 0$, so

$$(\mathbf{p}^{(k+1)})^\top \mathbf{r}^{(k+1)} = \|\mathbf{r}^{(k+1)}\|_2^2 + \beta_k (\mathbf{p}^{(k)})^\top \mathbf{r}^{(k+1)} = \|\mathbf{r}^{(k+1)}\|_2^2 > 0. \tag{$\dagger$}$$

Hence $\mathbf{p}^{(k+1)} \neq \mathbf{0}$, so $(\mathbf{p}^{(k+1)})^\top \mathbf{A}\mathbf{p}^{(k+1)} > 0$ and α_{k+1} is defined and positive.

Step 4: (a) for $k+1$. We must show $(\mathbf{p}^{(k+1)})^\top \mathbf{A}\mathbf{p}^{(j)} = 0$ for $j \leq k$. For $j = k$, use $\mathbf{A}\mathbf{p}^{(k)} = (\mathbf{r}^{(k)} - \mathbf{r}^{(k+1)})/\alpha_k$:

$$(\mathbf{p}^{(k+1)})^\top \mathbf{A}\mathbf{p}^{(k)} = (\mathbf{r}^{(k+1)})^\top \mathbf{A}\mathbf{p}^{(k)} + \beta_k (\mathbf{p}^{(k)})^\top \mathbf{A}\mathbf{p}^{(k)}.$$

By Step 1 the first term is $\big(0 - \|\mathbf{r}^{(k+1)}\|_2^2\big)/\alpha_k$, and $(\mathbf{p}^{(k)})^\top \mathbf{A}\mathbf{p}^{(k)} = \|\mathbf{r}^{(k)}\|_2^2/\alpha_k$ by the definition of α_k. The two cancel exactly when $\beta_k = \|\mathbf{r}^{(k+1)}\|_2^2/\|\mathbf{r}^{(k)}\|_2^2$, which is how β_k was defined. For $j < k$, the term $\beta_k (\mathbf{p}^{(k)})^\top \mathbf{A}\mathbf{p}^{(j)}$ vanishes by (a), and

$$\mathbf{A}\mathbf{p}^{(j)} = \frac{\mathbf{r}^{(j)} - \mathbf{r}^{(j+1)}}{\alpha_j} \in \operatorname{span}(\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(k)}),$$

so $(\mathbf{r}^{(k+1)})^\top \mathbf{A}\mathbf{p}^{(j)} = 0$ by Step 1.

Step 5: (b) for $k+1$. The first half is Step 1. For the second, $\mathbf{r}^{(k+2)} = \mathbf{r}^{(k+1)} - \alpha_{k+1}\mathbf{A}\mathbf{p}^{(k+1)}$, so for $j = k+1$,

$$(\mathbf{r}^{(k+2)})^\top \mathbf{p}^{(k+1)} = (\mathbf{r}^{(k+1)})^\top \mathbf{p}^{(k+1)} - \alpha_{k+1} (\mathbf{p}^{(k+1)})^\top \mathbf{A}\mathbf{p}^{(k+1)} = 0$$

by ($\dagger$) and the definition of α_{k+1}; and for $j \leq k$,

$$(\mathbf{r}^{(k+2)})^\top \mathbf{p}^{(j)} = (\mathbf{r}^{(k+1)})^\top \mathbf{p}^{(j)} - \alpha_{k+1} (\mathbf{p}^{(k+1)})^\top \mathbf{A}\mathbf{p}^{(j)} = 0 - 0 = 0$$

by (b) and Step 4. This completes the induction.

Proof of (d). By construction $\mathbf{x}^{(k+1)} = \mathbf{x}^{(0)} + \sum_{j \leq k} \alpha_j \mathbf{p}^{(j)}$, which lies in $\mathbf{x}^{(0)} + \mathcal{K}_{k+1}$ by (c). Let $\boldsymbol{\varepsilon} = \mathbf{x}^{(k+1)} - \mathbf{x}^\star$. By Eq. 23.7.1, $\mathbf{A}\boldsymbol{\varepsilon} = -\mathbf{r}^{(k+1)}$, so for every $\mathbf{w} \in \mathcal{K}_{k+1} = \operatorname{span}(\mathbf{p}^{(0)}, \dots, \mathbf{p}^{(k)})$,

$$\langle \boldsymbol{\varepsilon}, \mathbf{w} \rangle_{\mathbf{A}} = \mathbf{w}^\top \mathbf{A}\boldsymbol{\varepsilon} = -\mathbf{w}^\top \mathbf{r}^{(k+1)} = 0$$

by (b). Now take any $\mathbf{x} = \mathbf{x}^{(0)} + \mathbf{z}$ with $\mathbf{z} \in \mathcal{K}_{k+1}$, and write $\mathbf{x} - \mathbf{x}^\star = \boldsymbol{\varepsilon} + \mathbf{w}$ with $\mathbf{w} = \mathbf{z} - \sum_{j \leq k} \alpha_j \mathbf{p}^{(j)} \in \mathcal{K}_{k+1}$. By the Pythagorean theorem (Theorem 10.1.3) in the energy inner product,

$$\|\mathbf{x} - \mathbf{x}^\star\|_{\mathbf{A}}^2 = \|\boldsymbol{\varepsilon}\|_{\mathbf{A}}^2 + \|\mathbf{w}\|_{\mathbf{A}}^2 \;\geq\; \|\boldsymbol{\varepsilon}\|_{\mathbf{A}}^2,$$

with equality only for $\mathbf{w} = \mathbf{0}$, that is only for $\mathbf{x} = \mathbf{x}^{(k+1)}$. This proves the theorem.

■

Corollary 23.7.5 — Finite Termination

In exact arithmetic the conjugate gradient iteration reaches $\mathbf{r}^{(m)} = \mathbf{0}$, and hence $\mathbf{x}^{(m)} = \mathbf{x}^\star$, for some $m \le n$. If $\mathbf{A}$ has only d distinct eigenvalues, then $m \le d$.

Proof. Suppose $\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(k)}$ are all non-zero. By Theorem 23.7.4 (c), $\dim \mathcal{K}_{k+1} = k+1$. Since $\mathcal{K}_{k+1} \subseteq \mathbb{R}^n$, this forces $k+1 \le n$; so the residuals cannot all be non-zero for $k = n$, and $\mathbf{r}^{(m)} = \mathbf{0}$ for some $m \le n$. Then $\mathbf{A}\mathbf{x}^{(m)} = \mathbf{b}$, so $\mathbf{x}^{(m)} = \mathbf{x}^\star$.

For the refinement, let $\mu_1, \dots, \mu_d$ be the distinct eigenvalues and put $q(x) = (x - \mu_1)\cdots(x - \mu_d)$. By Corollary 11.5.2, $\mathbf{A} = \mathbf{Q}\mathbf{D}\mathbf{Q}^\top$ with $\mathbf{Q}$ orthogonal and $\mathbf{D}$ diagonal carrying the eigenvalues, so $q(\mathbf{A}) = \mathbf{Q}\, q(\mathbf{D})\, \mathbf{Q}^\top = 0$, every diagonal entry of $q(\mathbf{D})$ being q at an eigenvalue. Hence $\mathbf{A}^d\mathbf{r}^{(0)}$ is a combination of $\mathbf{r}^{(0)}, \mathbf{A}\mathbf{r}^{(0)}, \dots, \mathbf{A}^{d-1}\mathbf{r}^{(0)}$, so $\mathcal{K}_{d+1} = \mathcal{K}_d$ and $\dim \mathcal{K}_k \le d$ for every k. If $\mathbf{r}^{(0)}, \dots, \mathbf{r}^{(d)}$ were all non-zero we would get $\dim \mathcal{K}_{d+1} = d + 1 > d$, a contradiction. So $m \le d$. ∎

Example. (Two distinct eigenvalues, two steps)

Let $\mathbf{A} = \mathbf{I}_3 + \mathbf{J}$, where $\mathbf{J}$ is the all-ones matrix, let $\mathbf{b} = \mathbf{e}_1$ and $\mathbf{x}^{(0)} = \mathbf{0}$. Run CG.

Solution. $\mathbf{A}$ has rows $(2,1,1)$, $(1,2,1)$, $(1,1,2)$. Since $\mathbf{J}\mathbf{1} = 3\mathbf{1}$ and $\mathbf{J}$ kills $\mathbf{1}^\perp$, the eigenvalues of $\mathbf{A}$ are 4 (once) and 1 (twice): $d = 2$. Also $\mathbf{A}^{-1} = \mathbf{I} - \frac{1}{4}\mathbf{J}$, so $\mathbf{x}^\star = \mathbf{e}_1 - \frac{1}{4}\mathbf{1} = \left(\frac{3}{4}, -\frac{1}{4}, -\frac{1}{4}\right)$.

Step 0. $\mathbf{r}^{(0)} = \mathbf{p}^{(0)} = (1,0,0)$, $(\mathbf{r}^{(0)})^\top\mathbf{r}^{(0)} = 1$, $\mathbf{A}\mathbf{p}^{(0)} = (2,1,1)$, $(\mathbf{p}^{(0)})^\top\mathbf{A}\mathbf{p}^{(0)} = 2$, so $\alpha_0 = \frac{1}{2}$ and

$$\mathbf{x}^{(1)} = \left(\tfrac{1}{2}, 0, 0\right), \qquad \mathbf{r}^{(1)} = (1,0,0) - \tfrac{1}{2}(2,1,1) = \left(0, -\tfrac{1}{2}, -\tfrac{1}{2}\right).$$

Then $\beta_0 = \frac{1}{2}/1 = \frac{1}{2}$ and $\mathbf{p}^{(1)} = \left(0, -\frac{1}{2}, -\frac{1}{2}\right) + \frac{1}{2}(1,0,0) = \left(\frac{1}{2}, -\frac{1}{2}, -\frac{1}{2}\right)$.

Step 1. The rows of $\mathbf{A}$ applied to $\mathbf{p}^{(1)}$ give $1 - \frac{1}{2} - \frac{1}{2} = 0$, then $\frac{1}{2} - 1 - \frac{1}{2} = -1$, then $\frac{1}{2} - \frac{1}{2} - 1 = -1$; so $\mathbf{A}\mathbf{p}^{(1)} = (0,-1,-1)$ and $(\mathbf{p}^{(1)})^\top\mathbf{A}\mathbf{p}^{(1)} = 1$. With $(\mathbf{r}^{(1)})^\top\mathbf{r}^{(1)} = \frac{1}{2}$ this gives $\alpha_1 = \frac{1}{2}$ and

$$\mathbf{x}^{(2)} = \left(\tfrac{1}{2}, 0, 0\right) + \tfrac{1}{2}\left(\tfrac{1}{2}, -\tfrac{1}{2}, -\tfrac{1}{2}\right) = \left(\tfrac{3}{4}, -\tfrac{1}{4}, -\tfrac{1}{4}\right) = \mathbf{x}^\star,$$

with $\mathbf{r}^{(2)} = \left(0, -\frac{1}{2}, -\frac{1}{2}\right) - \frac{1}{2}(0,-1,-1) = \mathbf{0}$. Two steps, as Corollary 23.7.5 predicts, for a 3×3 system. Checks: $(\mathbf{r}^{(1)})^\top\mathbf{r}^{(0)} = 0$ and $(\mathbf{p}^{(1)})^\top\mathbf{A}\mathbf{p}^{(0)} = \left(\frac{1}{2}, -\frac{1}{2}, -\frac{1}{2}\right)\cdot(2,1,1) = 1 - \frac{1}{2} - \frac{1}{2} = 0$.

Warning. **Finite termination is a theorem about exact arithmetic, and it is not how CG is used.** In the floating-point model of Section 1 the computed residuals lose their orthogonality, as the Lanczos vectors of Section 6 do. The two algorithms are closely related: started from the same $\mathbf{A}$ and the same vector they build bases of the same Krylov spaces, and the tridiagonal matrix of Theorem 23.6.3 can be assembled from the CG coefficients — which are *not* the α_j and β_j of Theorem 23.6.3, those being the entries of that tridiagonal matrix, but different numbers. **That correspondence, due to Lanczos and to Hestenes and Stiefel, and the rounding behavior it carries across, due to Paige and Greenbaum, are described here and not proved; nothing in this section depends on either.** A run of CG on a matrix of order 10^6

is stopped after a few hundred steps, and the theorem that matters is Theorem 23.7.7 below.

23.7.4 Chebyshev polynomials

Theorem 23.7.4 (d) has an equivalent form that turns the whole question of speed into a question about polynomials, and that question has a classical answer. We need one family of polynomials and two facts about it.

The Chebyshev polynomials stay within 1 *on* $[-1,1]$ *and then grow geometrically outside it.*

Definition 23.7.4 — Chebyshev Polynomials

The **Chebyshev polynomials** $T_0, T_1, T_2, \dots \in \mathbb{R}[x]$ are defined by

$$T_0 = 1, \qquad T_1 = x, \qquad T_{k+1} = 2x\,T_k - T_{k-1} \quad (k \geq 1).$$

The name comes from Chapter 10. Its table at the end of §10 lists the **monic** orthogonal polynomial sequence of Definition 10.10.1 for the weight $(1-t^2)^{-1/2}$ on $(-1,1)$, and the T_k above are its members rescaled — which is why the recurrence here is not the one of Theorem 10.10.3, that theorem being stated for the monic normalization, where no factor 2 appears. The book has not proved that identification and nothing below uses it. Here the recurrence *is* the definition, and we prove what we need from it directly. The first few are

$$T_2 = 2x^2 - 1, \quad T_3 = 4x^3 - 3x, \quad T_4 = 8x^4 - 8x^2 + 1.$$

We shall need the degrees, and the recurrence supplies them by induction on k. For $k = 0$ and $k = 1$, $\deg T_k = k$, with leading coefficient 1 in both cases. Let $k \geq 1$ and suppose $\deg T_{k-1} = k-1$ and $\deg T_k = k$ with leading coefficient c_k. Then $2xT_k$ has degree $k+1$ with leading coefficient $2c_k$, while $\deg T_{k-1} = k-1 < k+1$, so no cancellation is possible in $T_{k+1} = 2xT_k - T_{k-1}$ and $\deg T_{k+1} = k+1$ with leading coefficient $2c_k$. Hence $\deg T_k = k$ for every k, and since $c_1 = 1$ the doubling gives $c_k = 2^{k-1}$ for $k \geq 1$.

The one trick in the subject is a change of variable. Every complex number x can be written as $\frac{1}{2}(w + w^{-1})$ for some $w \neq 0$: the equation $w^2 - 2xw + 1 = 0$ has two roots in $\mathbb{C}$, neither of them 0 since their product is 1. In that variable the recurrence becomes trivial.

Lemma 23.7.6 — Chebyshev Polynomials: Size Inside and Growth Outside

For every $k \geq 0$ and every $w \in \mathbb{C} \setminus \{0\}$,

$$T_k\Big(\frac{w + w^{-1}}{2}\Big) = \frac{w^k + w^{-k}}{2}. \tag{23.7.5}$$

Consequently:

(a) $|T_k(x)| \leq 1$ for every real $x \in [-1,1]$, and $T_k(1) = 1$;

(b) for every real $z > 1$,

$$T_k(z) = \tfrac{1}{2}\Big(\big(z+\sqrt{z^2-1}\big)^k + \big(z+\sqrt{z^2-1}\big)^{-k}\Big) \;\geq\; \tfrac{1}{2}\big(z+\sqrt{z^2-1}\big)^k,$$

and, separately, $T_k(z) \geq 1$.

Idea. Under $x = \frac{1}{2}(w + w^{-1})$ the recurrence of Definition 23.7.4 says nothing more than $w^{k+1} + w^{-(k+1)} = (w + w^{-1})(w^k + w^{-k}) - (w^{k-1} + w^{-(k-1)})$, which is true because the cross terms cancel. The two facts are then two choices of w: on $[-1, 1]$ take $|w| = 1$, so that w^k and w^{-k} are again on the unit circle; outside, take w real and greater than 1, so that w^k grows geometrically.

Proof. The identity Eq. 23.7.5. Induct on k. For $k = 0$ both sides are 1, and for $k = 1$ both are $\frac{1}{2}(w + w^{-1})$. Assume the identity for $k-1$ and k, with $k \geq 1$, and write $x = \frac{1}{2}(w + w^{-1})$. Then

$$\begin{aligned} T_{k+1}(x) &= 2x\,T_k(x) - T_{k-1}(x) \\ &= (w + w^{-1})\frac{w^k + w^{-k}}{2} - \frac{w^{k-1} + w^{-(k-1)}}{2} \\ &= \frac{w^{k+1} + w^{-(k-1)} + w^{k-1} + w^{-(k+1)} - w^{k-1} - w^{-(k-1)}}{2}, \end{aligned}$$

which is $\frac{1}{2}(w^{k+1} + w^{-(k+1)})$, as required.

(a). Let $x \in [-1, 1]$ and put $w = x + i\sqrt{1-x^2}$. Then $|w|^2 = x^2 + (1-x^2) = 1$, so $w \neq 0$ and $w^{-1} = \overline{w}$ (Theorem 0.6.2), whence $\frac{1}{2}(w + w^{-1}) = \frac{1}{2}(w + \overline{w}) = x$. By Eq. 23.7.5 and $|u + v| \leq |u| + |v|$ (Theorem 0.6.4),

$$|T_k(x)| = \tfrac{1}{2}|w^k + w^{-k}| \leq \tfrac{1}{2}\big(|w|^k + |w|^{-k}\big) = 1.$$

For $x = 1$ take $w = 1$, giving $T_k(1) = \frac{1}{2}(1 + 1) = 1$.

(b). Let $z > 1$ and put $w = z + \sqrt{z^2 - 1}$, a real number > 1. Then

$$w\big(z - \sqrt{z^2-1}\big) = z^2 - (z^2 - 1) = 1,$$

so $w^{-1} = z - \sqrt{z^2-1}$ and $\frac{1}{2}(w + w^{-1}) = z$. Now Eq. 23.7.5 gives the displayed formula. Both w^k and w^{-k} are positive, so dropping the second gives the displayed inequality. For the separate bound, $\frac{1}{2}(s + s^{-1}) \geq 1$ for every $s > 0$, because $s + s^{-1} - 2 = (s^{1/2} - s^{-1/2})^2 \geq 0$; applying this with $s = w^k > 0$ gives $T_k(z) = \frac{1}{2}(w^k + w^{-k}) \geq 1$. This proves the lemma.

■

Warning. **Part (a) is false the moment x leaves $[-1, 1]$, and spectacularly so.** $T_{10}(1.1)$ is already about 42.2, and $T_{50}(1.1)$ exceeds 2×10^9. That explosion is not a defect; it is the whole resource. The polynomial in the next theorem is small where the eigenvalues live and large at 0, and the ratio of the two is what CG converts into speed.

Remark. That the Chebyshev polynomials are also **extremal** — among monic polynomials of degree k, the scaled $T_k/2^{k-1}$ has the smallest maximum modulus on $[-1, 1]$ — is classical, is not proved here, and is not needed. What Theorem 23.7.7 uses is only that T_k, rescaled, is an admissible competitor in the minimum of Eq. 23.7.6: small on

the interval where the eigenvalues lie, and large at 0.

23.7.5 The square root

Theorem 23.7.7 — Convergence of Conjugate Gradients

Let $\mathbf{A} \in M_n(\mathbb{R})$ be symmetric positive definite with $\kappa = \kappa_2(\mathbf{A})$, let $\mathbf{b} \in \mathbb{R}^n$, and let $\mathbf{x}^{(k)}$ be the conjugate gradient iterates from $\mathbf{x}^{(0)}$, with $\mathbf{x}^{(k)} := \mathbf{x}^\star$ once the iteration has terminated. Then for every $k \geq 0$,

$$\|\mathbf{x}^{(k)} - \mathbf{x}^\star\|_{\mathbf{A}} \;\leq\; 2\Big(\frac{\sqrt{\kappa}-1}{\sqrt{\kappa}+1}\Big)^k \|\mathbf{x}^{(0)} - \mathbf{x}^\star\|_{\mathbf{A}}.$$

Idea. Three moves. ① Theorem 23.7.4 says the CG error is the smallest among all errors reachable from the Krylov space; writing out what "reachable" means turns that into: the smallest value of $\|q(\mathbf{A})\boldsymbol{\varepsilon}^{(0)}\|_{\mathbf{A}}$ over polynomials q of degree $\leq k$ with $q(0) = 1$. ② In an eigenbasis that quantity is at most $\max_i |q(\lambda_i)|$ times the initial error, so we need one polynomial that is 1 at 0 and small on $[\lambda_n, \lambda_1]$. ③ Chebyshev's polynomial, rescaled so that the interval becomes $[-1, 1]$, is that polynomial, and Lemma 23.7.6 measures it.

Proof. If $\kappa = 1$ then $\lambda_1 = \lambda_n$, so $\mathbf{A} = \lambda_1 \mathbf{I}$ by the spectral theorem, and $\mathbf{p}^{(0)} = \mathbf{r}^{(0)}$ gives $\alpha_0 = 1/\lambda_1$ and $\mathbf{x}^{(1)} = \mathbf{x}^\star$; the bound then reads $0 \leq 0$ for $k \geq 1$ and $\|\boldsymbol{\varepsilon}^{(0)}\|_{\mathbf{A}} \leq 2\|\boldsymbol{\varepsilon}^{(0)}\|_{\mathbf{A}}$ for $k = 0$, both true. So assume $\kappa > 1$. We may also assume the iteration has not terminated before step k, since once it has, the left-hand side is 0.

Step 1: the error is a polynomial in A applied to the initial error. Write $\boldsymbol{\varepsilon}^{(0)} = \mathbf{x}^{(0)} - \mathbf{x}^\star$, so $\mathbf{r}^{(0)} = -\mathbf{A}\boldsymbol{\varepsilon}^{(0)}$ by Eq. 23.7.1. A vector of $\mathbf{x}^{(0)} + \mathcal{K}_k$ has the form $\mathbf{x} = \mathbf{x}^{(0)} + \sum_{j=0}^{k-1} c_j \mathbf{A}^j \mathbf{r}^{(0)}$, and then

$$\mathbf{x} - \mathbf{x}^\star = \boldsymbol{\varepsilon}^{(0)} - \sum_{j=0}^{k-1} c_j \mathbf{A}^{j+1}\boldsymbol{\varepsilon}^{(0)} = q(\mathbf{A})\,\boldsymbol{\varepsilon}^{(0)}, \qquad q(x) = 1 - \sum_{j=0}^{k-1} c_j x^{j+1}.$$

As the c_j range over $\mathbb{R}^k$, q ranges over **all** polynomials of degree at most k with $q(0) = 1$. So Theorem 23.7.4 (d) says

$$\|\boldsymbol{\varepsilon}^{(k)}\|_{\mathbf{A}} = \min\big\{\|q(\mathbf{A})\boldsymbol{\varepsilon}^{(0)}\|_{\mathbf{A}} : \deg q \leq k,\ q(0) = 1\big\}. \tag{23.7.6}$$

Step 2: one eigenbasis estimate. By Corollary 11.5.2 take an orthonormal basis $\mathbf{q}_1, \ldots, \mathbf{q}_n$ with $\mathbf{A}\mathbf{q}_i = \lambda_i \mathbf{q}_i$, and write $\boldsymbol{\varepsilon}^{(0)} = \sum_i u_i \mathbf{q}_i$. Then $q(\mathbf{A})\mathbf{q}_i = q(\lambda_i)\mathbf{q}_i$, so

$$\|q(\mathbf{A})\boldsymbol{\varepsilon}^{(0)}\|_{\mathbf{A}}^2 = \sum_i \lambda_i\, q(\lambda_i)^2 u_i^2 \leq \Big(\max_i |q(\lambda_i)|\Big)^2 \sum_i \lambda_i u_i^2,$$

and $\sum_i \lambda_i u_i^2 = \|\boldsymbol{\varepsilon}^{(0)}\|_{\mathbf{A}}^2$. Every λ_i lies in $[\lambda_n, \lambda_1]$, so with Eq. 23.7.6, for any admissible q,

$$\|\boldsymbol{\varepsilon}^{(k)}\|_{\mathbf{A}} \leq \Big(\max_{\lambda_n \leq \lambda \leq \lambda_1} |q(\lambda)|\Big)\|\boldsymbol{\varepsilon}^{(0)}\|_{\mathbf{A}}. \tag{23.7.7}$$

Step 3: the polynomial. Put

$$z = \frac{\lambda_1 + \lambda_n}{\lambda_1 - \lambda_n} = \frac{\kappa + 1}{\kappa - 1} > 1, \qquad q(\lambda) = \frac{1}{T_k(z)}\, T_k\Big(\frac{\lambda_1 + \lambda_n - 2\lambda}{\lambda_1 - \lambda_n}\Big).$$

The inner expression is an affine function of λ carrying λ_n to 1 and λ_1 to -1, so it maps $[\lambda_n, \lambda_1]$ into $[-1, 1]$; and it sends $\lambda = 0$ to z. By Lemma 23.7.6 (b), $T_k(z) \geq 1 > 0$, so q is a well-defined polynomial of degree at most k, and $q(0) = T_k(z)/T_k(z) = 1$. By Lemma 23.7.6 (a),

$$\max_{\lambda_n \leq \lambda \leq \lambda_1} |q(\lambda)| \leq \frac{1}{T_k(z)}.$$

Step 4: measuring $T_k(z)$. Since $\kappa > 1$,

$$z^2 - 1 = \frac{(\kappa+1)^2 - (\kappa-1)^2}{(\kappa-1)^2} = \frac{4\kappa}{(\kappa-1)^2}, \qquad \sqrt{z^2-1} = \frac{2\sqrt{\kappa}}{\kappa - 1},$$

so, using $\kappa - 1 = (\sqrt{\kappa} - 1)(\sqrt{\kappa} + 1)$,

$$z + \sqrt{z^2-1} = \frac{\kappa + 1 + 2\sqrt{\kappa}}{\kappa - 1} = \frac{(\sqrt{\kappa}+1)^2}{(\sqrt{\kappa}-1)(\sqrt{\kappa}+1)} = \frac{\sqrt{\kappa}+1}{\sqrt{\kappa}-1}.$$

By Lemma 23.7.6 (b), $T_k(z) \geq \frac{1}{2}\big((\sqrt{\kappa}+1)/(\sqrt{\kappa}-1)\big)^k$, so $1/T_k(z) \leq 2\big((\sqrt{\kappa}-1)/(\sqrt{\kappa}+1)\big)^k$. Feeding this into Eq. 23.7.7 proves the theorem.

■

The square root is the whole gain. Take $\kappa = 100$. Steepest descent contracts by at most $99/101 \approx 0.9802$ per step, so reducing the energy-norm error by 10^{-6} needs about 691 steps; conjugate gradients contracts by $9/11 \approx 0.8182$, and $2(9/11)^k \leq 10^{-6}$ already at $k = 73$. Both cost one product with $\mathbf{A}$ per step, so the ratio of the counts is the ratio of the work.

Quick check. Why does the factor 2 in Theorem 23.7.7 cost so little, and why is it there at all?

Solution. It costs little because it is a constant against a geometric factor: absorbing it changes the step count by $\log 2 / \log\big((\sqrt{\kappa}+1)/(\sqrt{\kappa}-1)\big)$, about 3.5 steps out of 73 when $\kappa = 100$. It is there because the lower bound for $T_k(z)$ in Lemma 23.7.6 (b) throws away the term w^{-k}; the surviving $\frac{1}{2}$ is exactly this 2.

Remark. The bound uses only the two ends of the spectrum, and it is often pessimistic. Eq. 23.7.7 holds for *every* admissible polynomial, so if the eigenvalues fall into a few tight clusters one may take q small near each cluster and do far better; Corollary 23.7.5 is the extreme case. Conjugate gradients sees the whole spectrum, not just its ends.

23.7.6 Two footnotes: Chebyshev iteration and preconditioning

The polynomial in Step 3 depends only on λ_1 and λ_n, so one can *fix* it in advance and update the iterates by the recurrence of Definition 23.7.4. This is the **Chebyshev iteration**. Three

things are said about it: that it attains the bound of Theorem 23.7.7 rather than beating it; that it needs estimates of λ_1 and λ_n which CG does not; and that in exchange it forms no inner products, which matters when the work is split across many processors. **None of the three is proved here.** The method and its analysis are due to Golub and Varga, and nothing in this section depends on them.

Since the cost is governed by $\sqrt{\kappa}$, it pays to replace $\mathbf{A}\mathbf{x} = \mathbf{b}$ by an equivalent system of smaller condition number. Choosing a symmetric positive definite $\mathbf{M}$ close to $\mathbf{A}$, and writing $\mathbf{M} = \mathbf{C}\mathbf{C}^{\top}$, one applies CG to

$$(\mathbf{C}^{-1}\mathbf{A}\mathbf{C}^{-\top})\mathbf{y} = \mathbf{C}^{-1}\mathbf{b}, \qquad \mathbf{x} = \mathbf{C}^{-\top}\mathbf{y},$$

whose matrix is symmetric positive definite (Proposition 12.1.2) and whose eigenvalues are the generalized eigenvalues of the pencil $\mathbf{A} - \lambda\mathbf{M}$ of Definition 12.4.1, as Exercise C3 below asks you to check. This is **preconditioning**, and it is a subject rather than a theorem: which $\mathbf{M}$ to choose depends on where $\mathbf{A}$ came from, and no theorem of linear algebra answers that. We state the mechanism and stop.

23.7.7 Exercises

23.7.7.1 A. Check your understanding

Exercise A1.

(a) Define the energy inner product of a symmetric positive definite $\mathbf{A}$, and say which clause of Definition 12.1.1 makes it an inner product.

(b) State Proposition 23.7.1, and explain in one sentence why it makes $\|\cdot\|_{\mathbf{A}}$ the natural yardstick for the error.

(c) State the optimality property of the k-th conjugate gradient iterate, naming the set over which it is optimal.

(d) Determine whether the following statement is correct, and justify your answer: in exact arithmetic, conjugate gradients applied to a 1000×1000 positive definite matrix with 5 distinct eigenvalues terminates after at most 5 steps.

(e) Write down the two Chebyshev facts of Lemma 23.7.6, and say which of the two supplies the $\sqrt{\kappa}$ in Theorem 23.7.7.

Solution.

(a) $\langle \mathbf{x}, \mathbf{y} \rangle_{\mathbf{A}} = \mathbf{y}^{\top}\mathbf{A}\mathbf{x}$. Symmetry and bilinearity hold for any symmetric $\mathbf{A}$; what makes it an inner product is $\langle \mathbf{x}, \mathbf{x} \rangle_{\mathbf{A}} = \mathbf{x}^{\top}\mathbf{A}\mathbf{x} > 0$ for $\mathbf{x} \neq \mathbf{0}$, which is clause (P2) of Definition 12.1.1 in its strict form.

(b) $\phi(\mathbf{x}) - \phi(\mathbf{x}^{\star}) = \frac{1}{2}\|\mathbf{x} - \mathbf{x}^{\star}\|_{\mathbf{A}}^{2}$, where $\phi(\mathbf{x}) = \frac{1}{2}\mathbf{x}^{\top}\mathbf{A}\mathbf{x} - \mathbf{b}^{\top}\mathbf{x}$ and $\mathbf{x}^{\star} = \mathbf{A}^{-1}\mathbf{b}$. So the energy norm of the error *is* the excess of ϕ over its minimum, up to the factor $\frac{1}{2}$: it is the quantity every descent method is built to decrease.

(c) By Theorem 23.7.4 (d), $\mathbf{x}^{(k)}$ is the unique minimizer of $\|\mathbf{x} - \mathbf{x}^{\star}\|_{\mathbf{A}}$ over the affine set $\mathbf{x}^{(0)} + \mathcal{K}_k(\mathbf{A}, \mathbf{r}^{(0)})$.

(d) Correct. By Corollary 23.7.5 the number of steps is at most the number d of distinct eigenvalues, here 5, and the order 1000 plays no part. The proof is that $q(\mathbf{A}) = 0$ for the degree-5 polynomial with the distinct eigenvalues as roots, so the Krylov spaces stop growing at dimension 5.

(e) $|T_k| \le 1$ on $[-1,1]$, and $T_k(z) \ge \tfrac{1}{2}(z+\sqrt{z^2-1})^k$ for $z > 1$. The second supplies the square root: at $z = (\kappa+1)/(\kappa-1)$ the number $z+\sqrt{z^2-1}$ equals $(\sqrt{\kappa}+1)/(\sqrt{\kappa}-1)$, and the square root enters through $\sqrt{z^2-1} = 2\sqrt{\kappa}/(\kappa-1)$.

23.7.7.2 B. Practice

Exercise B1: Steepest descent by hand.

Let $\mathbf{A} = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}$, $\mathbf{b} = (2,1)$ and $\mathbf{x}^{(0)} = (0,0)$.

(a) Compute $\mathbf{x}^{(1)}$ and $\mathbf{x}^{(2)}$ by steepest descent.

(b) Compute $\|\mathbf{x}^{(k)} - \mathbf{x}^\star\|_{\mathbf{A}}^2$ for $k = 0,1,2$ and compare the ratios with the bound of Theorem 23.7.3.

Solution. Here $\mathbf{x}^\star = (1,1)$ and $\kappa = 2$, so the bound's factor is $(\kappa-1)/(\kappa+1) = \tfrac{1}{3}$.

(a) $\mathbf{r}^{(0)} = (2,1)$, $\mathbf{r}^\top\mathbf{r} = 5$, $\mathbf{r}^\top\mathbf{A}\mathbf{r} = 2\cdot 4 + 1 = 9$, so $t_0 = \tfrac{5}{9}$ and $\mathbf{x}^{(1)} = \left(\tfrac{10}{9}, \tfrac{5}{9}\right)$. Then $\mathbf{r}^{(1)} = (2,1) - \mathbf{A}\mathbf{x}^{(1)} = \left(2 - \tfrac{20}{9},\ 1 - \tfrac{5}{9}\right) = \left(-\tfrac{2}{9}, \tfrac{4}{9}\right)$. Now $\mathbf{r}^\top\mathbf{r} = \tfrac{20}{81}$ and $\mathbf{r}^\top\mathbf{A}\mathbf{r} = 2\cdot\tfrac{4}{81} + \tfrac{16}{81} = \tfrac{24}{81}$, so $t_1 = \tfrac{20}{24} = \tfrac{5}{6}$ and

$$\mathbf{x}^{(2)} = \left(\tfrac{10}{9} - \tfrac{5}{6}\cdot\tfrac{2}{9},\ \tfrac{5}{9} + \tfrac{5}{6}\cdot\tfrac{4}{9}\right) = \left(\tfrac{25}{27}, \tfrac{25}{27}\right).$$

(b) The errors are $(-1,-1)$, $\left(\tfrac{1}{9}, -\tfrac{4}{9}\right)$, $\left(-\tfrac{2}{27}, -\tfrac{2}{27}\right)$, with squared energy norms

$$3, \qquad 2\cdot\tfrac{1}{81} + \tfrac{16}{81} = \tfrac{18}{81} = \tfrac{2}{9}, \qquad 3\cdot\tfrac{4}{729} = \tfrac{4}{243}.$$

The ratios are $\tfrac{2}{27}$ and $\tfrac{2}{27}$, both well below the bound's $(\tfrac{1}{3})^2 = \tfrac{1}{9}$. The bound is not attained here because the initial residual does not split its weight equally between the two eigenvector directions, which is what equality in Lemma 23.7.2 demands.

Exercise B2: Conjugate gradients by hand.

Let $\mathbf{A} = \begin{pmatrix} 4 & 1 \\ 1 & 3 \end{pmatrix}$, $\mathbf{b} = (1,2)$ and $\mathbf{x}^{(0)} = (0,0)$. Run conjugate gradients to termination, and verify at each stage that the residuals are orthogonal and the directions $\mathbf{A}$-orthogonal.

Solution. $\det\mathbf{A} = 11$, so $\mathbf{x}^\star = \tfrac{1}{11}(3\cdot 1 - 1\cdot 2,\ -1\cdot 1 + 4\cdot 2) = \left(\tfrac{1}{11}, \tfrac{7}{11}\right)$.

Step 0. $\mathbf{r}^{(0)} = \mathbf{p}^{(0)} = (1,2)$; $(\mathbf{r}^{(0)})^\top\mathbf{r}^{(0)} = 5$; $\mathbf{A}\mathbf{p}^{(0)} = (6,7)$; $(\mathbf{p}^{(0)})^\top\mathbf{A}\mathbf{p}^{(0)} = 6 + 14 = 20$. So $\alpha_0 = \tfrac{1}{4}$, $\mathbf{x}^{(1)} = \left(\tfrac{1}{4}, \tfrac{1}{2}\right)$ and

$$\mathbf{r}^{(1)} = (1,2) - \tfrac{1}{4}(6,7) = \left(-\tfrac{1}{2}, \tfrac{1}{4}\right).$$

Check: $(\mathbf{r}^{(1)})^\top\mathbf{r}^{(0)} = -\tfrac{1}{2} + \tfrac{1}{2} = 0$. Then $(\mathbf{r}^{(1)})^\top\mathbf{r}^{(1)} = \tfrac{1}{4} + \tfrac{1}{16} = \tfrac{5}{16}$, $\beta_0 = \tfrac{5/16}{5} = \tfrac{1}{16}$ and

$$\mathbf{p}^{(1)} = \left(-\tfrac{1}{2}, \tfrac{1}{4}\right) + \tfrac{1}{16}(1,2) = \left(-\tfrac{7}{16}, \tfrac{3}{8}\right).$$

Check: $(\mathbf{p}^{(1)})^\top\mathbf{A}\mathbf{p}^{(0)} = \left(-\tfrac{7}{16}\right)6 + \tfrac{3}{8}\cdot 7 = -\tfrac{42}{16} + \tfrac{42}{16} = 0$.

Step 1. $\mathbf{A}\mathbf{p}^{(1)} = \big(4(-\tfrac{7}{16}) + \tfrac{3}{8},\ -\tfrac{7}{16} + 3\cdot\tfrac{3}{8}\big) = \big(-\tfrac{11}{8}, \tfrac{11}{16}\big)$, so

$$(\mathbf{p}^{(1)})^{\top}\mathbf{A}\mathbf{p}^{(1)} = \tfrac{77}{128} + \tfrac{33}{128} = \tfrac{55}{64}, \qquad \alpha_1 = \frac{5/16}{55/64} = \frac{4}{11}.$$

Then

$$\mathbf{x}^{(2)} = \big(\tfrac{1}{4}, \tfrac{1}{2}\big) + \tfrac{4}{11}\big(-\tfrac{7}{16}, \tfrac{3}{8}\big) = \big(\tfrac{11}{44} - \tfrac{7}{44},\ \tfrac{11}{22} + \tfrac{3}{22}\big) = \big(\tfrac{1}{11}, \tfrac{7}{11}\big) = \mathbf{x}^{\star},$$

and

$$\mathbf{r}^{(2)} = \big(-\tfrac{1}{2}, \tfrac{1}{4}\big) - \tfrac{4}{11}\big(-\tfrac{11}{8}, \tfrac{11}{16}\big) = \big(-\tfrac{1}{2} + \tfrac{1}{2},\ \tfrac{1}{4} - \tfrac{1}{4}\big) = \mathbf{0}.$$

Two steps for a 2×2 system, which is what Corollary 23.7.5 allows.

Exercise B3: Chebyshev by recurrence.

(a) Compute T_5 from Definition 23.7.4.

(b) Evaluate $T_5(1)$, $T_5(-1)$ and $T_5(0)$, and check them against Lemma 23.7.6 (a).

(c) Evaluate $T_5(2)$ from the polynomial, and check it against the closed formula of Lemma 23.7.6 (b).

Solution.

(a) $T_2 = 2x^2 - 1$, $T_3 = 2x(2x^2 - 1) - x = 4x^3 - 3x$, $T_4 = 2x(4x^3 - 3x) - (2x^2 - 1) = 8x^4 - 8x^2 + 1$, and

$$T_5 = 2x(8x^4 - 8x^2 + 1) - (4x^3 - 3x) = 16x^5 - 20x^3 + 5x.$$

(b) $T_5(1) = 16 - 20 + 5 = 1$, $T_5(-1) = -1$, $T_5(0) = 0$. All three have absolute value at most 1, as (a) of the lemma requires, and the first is the equality $T_k(1) = 1$.

(c) $T_5(2) = 16 \cdot 32 - 20 \cdot 8 + 10 = 512 - 160 + 10 = 362$. By the closed formula with $z = 2$, $w = 2 + \sqrt{3}$ and $w^{-1} = 2 - \sqrt{3}$, so

$$T_5(2) = \tfrac{1}{2}\big((2 + \sqrt{3})^5 + (2 - \sqrt{3})^5\big).$$

Expanding, $(2 \pm \sqrt{3})^5 = 362 \pm 209\sqrt{3}$, so the half-sum is 362. The two agree, and the growth is visible: T_5 is at most 1 on $[-1, 1]$ and already 362 at 2.

23.7.7.3 C. Going deeper

Exercise C1: Sharpness of Kantorovich.

Let $a \geq c > 0$ and let $\mathbf{A} = \operatorname{diag}(a, c)$.

(a) Prove that for $\mathbf{y} = (1, 1)$ the inequality of Lemma 23.7.2 is an equality.

(b) Hence deduce that the constant $(\kappa - 1)/(\kappa + 1)$ in Theorem 23.7.3 cannot be replaced by any smaller one.

Solution.

(a) $\mathbf{y}^{\top}\mathbf{A}\mathbf{y} = a + c$, $\mathbf{y}^{\top}\mathbf{A}^{-1}\mathbf{y} = a^{-1} + c^{-1} = (a + c)/(ac)$, and $\mathbf{y}^{\top}\mathbf{y} = 2$. So the left side is $(a + c)^2/(ac)$ and the right side is $\big((a + c)^2/(4ac)\big) \cdot 4 = (a + c)^2/(ac)$. They

agree.

(b) Take $\mathbf{b} = (a, c)$, so that $\mathbf{x}^\star = (1, 1)$, and $\mathbf{x}^{(0)} = \big(1 - \tfrac{1}{a},\ 1 - \tfrac{1}{c}\big)$, so that $\boldsymbol{\varepsilon}^{(0)} = \big(-\tfrac{1}{a}, -\tfrac{1}{c}\big)$. Then $\mathbf{r}^{(0)} = -\mathbf{A}\boldsymbol{\varepsilon}^{(0)} = (1, 1)$, which is the vector of part (a). By the proof of Theorem 23.7.3 the one-step ratio is

$$1 - \frac{(\mathbf{r}^\top \mathbf{r})^2}{(\mathbf{r}^\top \mathbf{A}\mathbf{r})(\mathbf{r}^\top \mathbf{A}^{-1}\mathbf{r})} = 1 - \frac{4ac}{(a+c)^2} = \Big(\frac{\kappa - 1}{\kappa + 1}\Big)^2,$$

so the first step attains the bound exactly. Moreover $\mathbf{r}^{(1)} = \mathbf{r}^{(0)} - t_0 \mathbf{A}\mathbf{r}^{(0)} = (1 - t_0 a,\ 1 - t_0 c)$ with $t_0 = 2/(a+c)$, giving $\mathbf{r}^{(1)} = \big((c-a)/(a+c)\big)(1, -1)$; its two components again have equal absolute value, so part (a) applies to it up to sign and scale. That is enough: replacing $\mathbf{y}$ by $s\mathbf{y}$ multiplies both sides of Lemma 23.7.2 by s^4, and changing the sign of a coordinate changes neither side, since $\mathbf{A}$ and $\mathbf{A}^{-1}$ are diagonal. So every step attains the bound. Hence no constant smaller than $(\kappa - 1)/(\kappa + 1)$ can work. (Example (The bound is attained) is the case $a = 9$, $c = 1$, rescaled.)

Exercise C2: Finite termination, from polynomials.

Give a second proof of the second statement of Corollary 23.7.5 — that d distinct eigenvalues force termination in at most d steps — using Eq. 23.7.6 instead of a dimension count. *Hint: consider* $q(x) = \prod_{i=1}^{d} (1 - x/\mu_i)$.

Solution. Let $\mu_1, \dots, \mu_d$ be the distinct eigenvalues of $\mathbf{A}$; all are positive, so $q(x) = \prod_{i=1}^{d}(1 - x/\mu_i)$ is defined, has degree d, and satisfies $q(0) = 1$. It is therefore admissible in Eq. 23.7.6 with $k = d$. By Step 2 of the proof of Theorem 23.7.7,

$$\|\boldsymbol{\varepsilon}^{(d)}\|_{\mathbf{A}}^2 \le \sum_i \lambda_i\, q(\lambda_i)^2 u_i^2 = 0,$$

since every eigenvalue λ_i of $\mathbf{A}$ equals some μ_j and so is a root of q. Hence $\boldsymbol{\varepsilon}^{(d)} = \mathbf{0}$ and $\mathbf{x}^{(d)} = \mathbf{x}^\star$. (Eq. 23.7.6 was stated for iterates before termination; if the iteration stops earlier the conclusion is immediate.)

Exercise C3: What preconditioning does to the spectrum.

Let $\mathbf{A}, \mathbf{M} \in M_n(\mathbb{R})$ be symmetric positive definite and write $\mathbf{M} = \mathbf{C}\mathbf{C}^\top$ with $\mathbf{C}$ invertible, which is possible by Theorem 12.2.3.

(a) Prove that $\mathbf{C}^{-1}\mathbf{A}\mathbf{C}^{-\top}$ is symmetric positive definite.

(b) Prove that $\mathbf{C}^{-1}\mathbf{A}\mathbf{C}^{-\top}$ and $\mathbf{M}^{-1}\mathbf{A}$ are similar, and deduce that their eigenvalues coincide.

(c) Hence show that those eigenvalues are exactly the generalized eigenvalues of the pencil $\mathbf{A} - \lambda\mathbf{M}$ in the sense of Definition 12.4.1, and say what Theorem 23.7.7 then predicts for preconditioned conjugate gradients.

Solution.

(a) It is symmetric because $(\mathbf{C}^{-1}\mathbf{A}\mathbf{C}^{-\top})^\top = \mathbf{C}^{-1}\mathbf{A}^\top\mathbf{C}^{-\top} = \mathbf{C}^{-1}\mathbf{A}\mathbf{C}^{-\top}$. It is positive

definite by Proposition 12.1.2 (b) applied with $\mathbf{S} = \mathbf{C}^{-\top}$, which is invertible.

(b) Put $\mathbf{P} = \mathbf{C}^{-\top}$, which is invertible. Then

$$\mathbf{P}\big(\mathbf{C}^{-1}\mathbf{A}\mathbf{C}^{-\top}\big)\mathbf{P}^{-1} = \mathbf{C}^{-\top}\mathbf{C}^{-1}\mathbf{A}\mathbf{C}^{-\top}\mathbf{C}^{\top} = \mathbf{C}^{-\top}\mathbf{C}^{-1}\mathbf{A} = (\mathbf{C}\mathbf{C}^{\top})^{-1}\mathbf{A} = \mathbf{M}^{-1}\mathbf{A},$$

using $(\mathbf{C}\mathbf{C}^{\top})^{-1} = \mathbf{C}^{-\top}\mathbf{C}^{-1}$. So the two matrices are similar, and similar matrices have the same characteristic polynomial (Theorem 6.10.3), hence the same eigenvalues with multiplicity.

(c) By Definition 12.4.1, λ is a generalized eigenvalue of the pencil $\mathbf{A} - \lambda\mathbf{M}$ exactly when $\mathbf{A}\mathbf{v} = \lambda\mathbf{M}\mathbf{v}$ for some $\mathbf{v} \neq \mathbf{0}$, that is when $\mathbf{M}^{-1}\mathbf{A}\mathbf{v} = \lambda\mathbf{v}$; so the generalized eigenvalues are the eigenvalues of $\mathbf{M}^{-1}\mathbf{A}$, which by (b) are those of $\mathbf{C}^{-1}\mathbf{A}\mathbf{C}^{-\top}$. Running conjugate gradients on $(\mathbf{C}^{-1}\mathbf{A}\mathbf{C}^{-\top})\mathbf{y} = \mathbf{C}^{-1}\mathbf{b}$ therefore converges at the rate of Theorem 23.7.7 with κ replaced by the ratio of the largest to the smallest generalized eigenvalue of $\mathbf{A}$ relative to $\mathbf{M}$. Choosing $\mathbf{M}$ close to $\mathbf{A}$ makes that ratio close to 1; choosing $\mathbf{M} = \mathbf{A}$ makes it exactly 1, at the cost of having to solve with $\mathbf{A}$.

23.8 Lax Pairs and the Toda Flow

The QR algorithm of Section 5 is a sequence $\mathbf{A}^{(1)}, \mathbf{A}^{(2)}, \mathbf{A}^{(3)}, \dots$ of matrices, each similar to the last, drifting towards triangular form. Nothing in it looks like a differential equation. This section shows that it is one: there is a curve $Ł(t)$ of matrices, all with the same eigenvalues, that passes through the QR iterates at the integer times. The bridge is a class of matrix differential equations whose solutions cannot change their spectrum, and the proof that they cannot is a page of pure algebra. It is the one place in the chapter where nothing is computed and nothing is rounded.

Throughout, $I \subseteq \mathbb{R}$ is an open interval and matrix-valued functions of $t \in I$ are differentiated entrywise, as in Definition 15.6.1. **In this section the letter Ł names the matrix being flowed**, following the universal notation for it; the graph Laplacian of Section 11 carries the same symbol and never appears here.

23.8.1 Which matrix differential equations preserve the spectrum?

Start from the answer we want and read the equation off it. Suppose $Ł(t)$ is a curve of matrices, all similar to $Ł(0)$ by a similarity that also moves with t:

$$Ł(t) = \mathbf{S}(t)\, Ł(0)\, \mathbf{S}(t)^{-1},$$

with $\mathbf{S}\colon I \to M_n(\mathbb{C})$ differentiable and everywhere invertible. Differentiate. By the product rule (Lemma 15.6.4) and the derivative of the inverse (Theorem 15.6.5),

$$\begin{aligned} Ł' &= \mathbf{S}'Ł(0)\mathbf{S}^{-1} - \mathbf{S}Ł(0)\mathbf{S}^{-1}\mathbf{S}'\mathbf{S}^{-1} \\ &= (\mathbf{S}'\mathbf{S}^{-1})Ł - Ł(\mathbf{S}'\mathbf{S}^{-1}), \end{aligned}$$

where the second line inserts $\mathbf{S}^{-1}\mathbf{S} = \mathbf{I}$ in the first term and recognizes $\mathbf{S}Ł(0)\mathbf{S}^{-1} = Ł$ in both. So with $\mathbf{B} = \mathbf{S}'\mathbf{S}^{-1}$ the curve satisfies $Ł' = \mathbf{B}Ł - Ł\mathbf{B}$. The commutator is not a clever choice: it is what a moving similarity is *forced* to satisfy.

A Lax pair is a matrix that moves, together with the infinitesimal similarity that moves it.

Definition 23.8.1 — Lax Pair

Let $I \subseteq \mathbb{R}$ be an open interval. A **Lax pair** on I is a pair of functions $Ł, \mathbf{B}\colon I \to M_n(\mathbb{C})$, with $Ł$ differentiable, such that

$$Ł'(t) = [\mathbf{B}(t), Ł(t)] := \mathbf{B}(t)Ł(t) - Ł(t)\mathbf{B}(t) \qquad \text{for every } t \in I.$$

The equation itself is called a **Lax equation**, and $Ł$ is said to **flow** under it.

Clause by clause. The two matrices are **square of the same size** n, or the bracket is not defined. Only $Ł$ is required to be **differentiable**; $\mathbf{B}$ may be any function of t whatsoever, and in the interesting cases it is built out of $Ł(t)$ itself, which makes the equation non-linear. The bracket $[\mathbf{B}, Ł]$ is the commutator of the notation list, and the **order matters**: $[Ł, \mathbf{B}] = -[\mathbf{B}, Ł]$, so swapping the two letters runs the flow backwards.

Examples.

1. $\mathbf{B} = 0$**.** Then $Ł' = 0$, so $Ł$ is constant. The degenerate case, and it matters: it is the sanity check that the definition does not force motion.
2. **Constant B.** Put $Ł(t) = e^{t\mathbf{B}} Ł_0 e^{-t\mathbf{B}}$ for a fixed $Ł_0$. By Theorem 9.9.4 (b) and Lemma 15.6.4,

$$Ł'(t) = \mathbf{B}e^{t\mathbf{B}}Ł_0e^{-t\mathbf{B}} + e^{t\mathbf{B}}Ł_0(-\mathbf{B}e^{-t\mathbf{B}}) = \mathbf{B}Ł - Ł\mathbf{B},$$

the last step because $\mathbf{B}$ commutes with $e^{\pm t\mathbf{B}}$, again by Theorem 9.9.4 (b). So $(Ł, \mathbf{B})$ is a Lax pair on all of $\mathbb{R}$. Corollary 23.8.2 below says these are the only solutions when $\mathbf{B}$ is constant.

A third example is worth a block of its own, because it is the one to hold in mind.

Example. (A curve of matrices with a frozen spectrum)

Take $\mathbf{B} = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and $Ł_0 = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$. Since $\mathbf{B}^2 = 0$, Definition 9.9.2 gives $e^{t\mathbf{B}} = \mathbf{I} + t\mathbf{B}$, and the recipe of the previous example produces

$$Ł(t) = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & -t \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} t & -t^2 \\ 1 & -t \end{pmatrix}.$$

Three of the four entries move — only the corner $\ell_{21} = 1$ stands still — and yet $\operatorname{tr} Ł(t) = 0$ and $\det Ł(t) = -t^2 + t^2 = 0$, so $p_{Ł(t)}(x) = x^2$ for every t. The curve stays inside one similarity class the whole time.

A non-example, by dropping the second term. Replace the Lax equation by $Ł' = \mathbf{B}Ł$ with $\mathbf{B} = \mathbf{I}$. The unique solution with $Ł(0) = Ł_0$ is $Ł(t) = e^t Ł_0$ (Theorem 9.9.6, applied to each column). Its eigenvalues are $e^t\lambda_i$, which move. What was lost is precisely the second term: $\mathbf{B}Ł$ alone is not a commutator, and a commutator is what the differentiation of a similarity produced.

Warning. **Isospectral does not mean constant.** In Example (A curve of matrices with a frozen spectrum) the matrix $Ł(t)$ changes at every instant; what stays put is its list of eigenvalues. The eigen*vectors* move, and they must, since they are the columns of $\mathbf{S}(t)$ up to scale. A flow that fixed the eigenvectors as well would fix $Ł$. The whole use

of a Lax pair — in Section 5's language, in this section's, and in the theory of integrable systems generally — is that something moves while something else does not.

23.8.2 The isospectral theorem

The derivation above suggests the proof: manufacture $\mathbf{S}(t)$ and conclude by similarity. That route runs into an obstacle the book cannot clear. The natural $\mathbf{S}$ is the solution of $\mathbf{S}' = \mathbf{B}\mathbf{S}$, $\mathbf{S}(t_0) = \mathbf{I}$, and for a **constant** $\mathbf{B}$ that is $e^{(t-t_0)\mathbf{B}}$ by Chapter 9 §09. For a $\mathbf{B}$ that depends on t — the only case of interest here — the existence of such an $\mathbf{S}$ is a theorem about linear differential equations with variable coefficients, and this book does not prove it. So we take a different route, which needs no flow at all.

Theorem 23.8.1 — Lax Pairs Are Isospectral

Let $(Ł, \mathbf{B})$ be a Lax pair on an open interval I. Then the characteristic polynomial of $Ł(t)$ does not depend on t:

$$p_{Ł(t)} = p_{Ł(s)} \qquad \text{for all } s, t \in I.$$

In particular $Ł(t)$ has the same eigenvalues as $Ł(s)$, with the same algebraic multiplicities, and $\operatorname{tr} Ł(t)$ and $\det Ł(t)$ are constant.

Idea. Freeze $x \in \mathbb{C}$ and watch the single number $f(t) = \det(x\mathbf{I} - Ł(t))$. Jacobi's formula turns its derivative into a trace against the adjugate, and the adjugate is the one matrix that turns $\mathbf{M}$ into the scalar $\det \mathbf{M}$ from either side. Writing the bracket in terms of $\mathbf{M} = x\mathbf{I} - Ł$ rather than $Ł$ — which is legitimate, because $x\mathbf{I}$ commutes with everything — makes the two halves of the trace cancel, because a trace is unchanged by a cyclic shift. So $f' \equiv 0$, and a polynomial identity valid for every x is an identity of polynomials.

Proof. Fix $x \in \mathbb{C}$ and put $\mathbf{M}(t) = x\mathbf{I} - Ł(t)$, which is differentiable with $\mathbf{M}'(t) = -Ł'(t)$ (Definition 15.6.1). Let

$$f(t) = \det \mathbf{M}(t) = p_{Ł(t)}(x).$$

By Jacobi's formula (Theorem 15.6.6), f is differentiable on I with

$$f'(t) = \operatorname{tr}\big(\operatorname{adj} \mathbf{M}(t)\, \mathbf{M}'(t)\big).$$

Rewrite the bracket in terms of $\mathbf{M}$. Since $Ł = x\mathbf{I} - \mathbf{M}$ and $x\mathbf{I}$ commutes with $\mathbf{B}$,

$$[\mathbf{B}, Ł] = \mathbf{B}(x\mathbf{I} - \mathbf{M}) - (x\mathbf{I} - \mathbf{M})\mathbf{B} = \mathbf{M}\mathbf{B} - \mathbf{B}\mathbf{M},$$

so $\mathbf{M}' = -Ł' = -[\mathbf{B}, Ł] = \mathbf{B}\mathbf{M} - \mathbf{M}\mathbf{B}$. Writing $\mathbf{M} = \mathbf{M}(t)$ and using the linearity of the trace (Theorem 0.9.6 (1)),

$$f'(t) = \operatorname{tr}\big(\operatorname{adj} \mathbf{M}\, \mathbf{B}\mathbf{M}\big) - \operatorname{tr}\big(\operatorname{adj} \mathbf{M}\, \mathbf{M}\mathbf{B}\big).$$

A cyclic shift (Theorem 0.9.6 (3)) moves $\mathbf{M}$ to the front of the first trace, so

$$f'(t) = \operatorname{tr}\big(\mathbf{M}\, \operatorname{adj} \mathbf{M}\, \mathbf{B}\big) - \operatorname{tr}\big(\operatorname{adj} \mathbf{M}\, \mathbf{M}\, \mathbf{B}\big).$$

By Theorem 6.6.2, $\mathbf{M}\operatorname{adj}\mathbf{M} = \operatorname{adj}\mathbf{M}\,\mathbf{M} = (\det\mathbf{M})\mathbf{I}$, so the two traces are the same number and $f'(t) = 0$ for every $t \in I$.

A differentiable function on an interval with vanishing derivative is constant — the mean value theorem, fact (A6) of Chapter 15's introduction, applied to the real and imaginary parts of f. (Chapter 9 §09's fact (A4) says this for functions defined on all of $\mathbb{R}$, which is not the hypothesis here.) So $p_{Ł(t)}(x) = p_{Ł(s)}(x)$ for all $s, t \in I$.

Finally, $x \in \mathbb{C}$ was arbitrary, so the two polynomials $p_{Ł(t)}$ and $p_{Ł(s)}$ define the same function $\mathbb{C} \to \mathbb{C}$; since $\mathbb{C}$ is infinite, Theorem 5.1.5 (b) gives $p_{Ł(t)} = p_{Ł(s)}$ as polynomials. The eigenvalues are their roots and the multiplicities the multiplicities of those roots, and tr and det are two of the coefficients up to sign (Theorem 6.10.2). This proves the theorem.

■

Remark. **What the proof did not need.** It never produced the similarity $\mathbf{S}(t)$, never solved a differential equation, and never used any property of $\mathbf{B}$ — not continuity, and not differentiability. The only analytic ingredients are two: (D1), the differentiation package Chapter 15 §06 quoted, which is what Jacobi's formula rests on, and the mean value theorem (A6) of Chapter 15's introduction, in the form "zero derivative on an interval implies constant". Everything else is the adjugate identity and the invariance of the trace under a cyclic shift.

When $\mathbf{B}$ *is* constant, the similarity is available and the theorem can be sharpened: the flow is completely determined.

Corollary 23.8.2 — Constant $\mathbf{B}$: the flow is conjugation by the exponential

Let $\mathbf{B} \in M_n(\mathbb{C})$ be a fixed matrix and let $Ł\colon \mathbb{R} \to M_n(\mathbb{C})$ be differentiable with $Ł' = [\mathbf{B}, Ł]$. Then

$$Ł(t) = e^{t\mathbf{B}}\,Ł(0)\,e^{-t\mathbf{B}} \qquad (t \in \mathbb{R}),$$

so $Ł(t)$ is similar to $Ł(0)$ for every t.

Proof. Put $\mathbf{M}(t) = e^{-t\mathbf{B}}Ł(t)e^{t\mathbf{B}}$, a product of three differentiable matrix functions. By Lemma 15.6.4 and Theorem 9.9.4 (b), which also gives $\mathbf{B}e^{\pm t\mathbf{B}} = e^{\pm t\mathbf{B}}\mathbf{B}$,

$$\begin{aligned}\mathbf{M}'(t) &= -\mathbf{B}e^{-t\mathbf{B}}Ł e^{t\mathbf{B}} + e^{-t\mathbf{B}}Ł' e^{t\mathbf{B}} + e^{-t\mathbf{B}}Ł\mathbf{B}e^{t\mathbf{B}} \\ &= e^{-t\mathbf{B}}\big(-\mathbf{B}Ł + (\mathbf{B}Ł - Ł\mathbf{B}) + Ł\mathbf{B}\big)e^{t\mathbf{B}} = 0.\end{aligned}$$

By fact (A4) of Chapter 9 §09, every entry of $\mathbf{M}$ is constant, so $\mathbf{M}(t) = \mathbf{M}(0) = Ł(0)$. Multiplying on the left by $e^{t\mathbf{B}}$ and on the right by $e^{-t\mathbf{B}}$, and using $(e^{t\mathbf{B}})^{-1} = e^{-t\mathbf{B}}$ from Theorem 9.9.4 (c), gives the formula. This proves the corollary.

■

Quick check. Prove directly from the Lax equation, without Theorem 23.8.1, that $\operatorname{tr}Ł(t)$ is constant.

Solution. The trace of a matrix is a linear function of its entries, so $(\operatorname{tr} Ł)'(t) = \operatorname{tr}(Ł'(t))$ by (D1) and Theorem 0.9.6 (1). Then

$$\operatorname{tr} Ł'(t) = \operatorname{tr}(\mathbf{B}Ł) - \operatorname{tr}(Ł\mathbf{B}) = 0$$

by Theorem 0.9.6 (3). So $\operatorname{tr} Ł$ has zero derivative on I and is constant by fact (A6) of Chapter 15's introduction. The same argument applied to $Ł^m$ gives $\operatorname{tr}(Ł^m)' = 0$ for every $m \geq 1$ (Exercise (C1: The power sums are constants of the motion)).

23.8.3 The Toda flow

Now for the flow that matters. Take $Ł$ real symmetric and tridiagonal, and take $\mathbf{B}$ to be the skew-symmetric matrix built from the off-diagonal entries of $Ł$. There are two sign conventions, differing by $\mathbf{B} \mapsto -\mathbf{B}$ and so running the flow in opposite directions; we fix the one that drives the largest eigenvalue towards the top-left corner, as Example (The 2×2 flow, twice) will confirm.

Definition 23.8.2 — The Toda Flow

For $\mathbf{M} \in M_n(\mathbb{R})$ write $\mathbf{M}_+$ for its **strictly upper triangular part** and $\mathbf{M}_-$ for its **strictly lower triangular part**, so that $\mathbf{M}$ is the sum of $\mathbf{M}_-$, its diagonal part and $\mathbf{M}_+$, and set

$$\mathbf{B}(\mathbf{M}) := \mathbf{M}_+ - \mathbf{M}_-.$$

The **Toda flow** is the Lax equation

$$Ł'(t) = \big[\mathbf{B}(Ł(t)),\ Ł(t)\big]$$

for a differentiable $Ł\colon I \to M_n(\mathbb{R})$ taking symmetric tridiagonal values.

Two clauses need checking. First, $\mathbf{B}(\mathbf{M})$ is **skew-symmetric** when $\mathbf{M}$ is symmetric: transposing turns the strictly upper part into the strictly lower part of $\mathbf{M}^\top = \mathbf{M}$, so $\mathbf{B}(\mathbf{M})^\top = \mathbf{M}_- - \mathbf{M}_+ = -\mathbf{B}(\mathbf{M})$. Second, the equation is **non-linear**: $\mathbf{B}$ depends on $Ł$, and the right-hand side is quadratic in the entries of $Ł$. That is what makes it a genuine dynamical system rather than a rewriting of Corollary 23.8.2.

Writing the equation out shows what it does.

Proposition 23.8.3 — The Toda Flow in Coordinates

Let $Ł \in M_n(\mathbb{R})$ be symmetric and tridiagonal, with diagonal entries $d_1, \dots, d_n$ and off-diagonal entries $e_1, \dots, e_{n-1}$, so $\ell_{i,i+1} = \ell_{i+1,i} = e_i$. Put $e_0 = e_n = 0$. Then $[\mathbf{B}(Ł), Ł]$ is again symmetric and tridiagonal, with

$$\big[\mathbf{B}(Ł), Ł\big]_{ii} = 2\big(e_i^2 - e_{i-1}^2\big), \qquad \big[\mathbf{B}(Ł), Ł\big]_{i,i+1} = e_i\,(d_{i+1} - d_i).$$

Consequently the Toda flow is the system

$$d_i' = 2\big(e_i^2 - e_{i-1}^2\big) \quad (1 \le i \le n), \qquad e_i' = e_i\,(d_{i+1} - d_i) \quad (1 \le i \le n-1). \tag{23.8.1}$$

Proof. Write $\mathbf{B} = \mathbf{B}(Ł)$, so that $b_{i,i+1} = e_i$, $b_{i+1,i} = -e_i$, and every other entry of $\mathbf{B}$ is 0. Then for all i, j,

$$(\mathbf{B}Ł)_{ij} = e_i\,\ell_{i+1,j} - e_{i-1}\,\ell_{i-1,j}, \qquad (Ł\mathbf{B})_{ij} = e_{j-1}\,\ell_{i,j-1} - e_j\,\ell_{i,j+1},$$

with the convention that a term with an index outside $1, \dots, n$ is 0; this is just the two non-zero entries in row i of $\mathbf{B}$, respectively in column j of $\mathbf{B}$. Write $\mathbf{C} = \mathbf{B}Ł - Ł\mathbf{B}$, so

$$c_{ij} = e_i\ell_{i+1,j} - e_{i-1}\ell_{i-1,j} - e_{j-1}\ell_{i,j-1} + e_j\ell_{i,j+1}. \tag{$*$}$$

$\mathbf{C}$ is symmetric: since $\mathbf{B}^\top = -\mathbf{B}$ and $Ł^\top = Ł$,

$$\mathbf{C}^\top = Ł^\top\mathbf{B}^\top - \mathbf{B}^\top Ł^\top = -Ł\mathbf{B} + \mathbf{B}Ł = \mathbf{C},$$

so it is enough to compute c_{ij} for $j \ge i$.

Case $j = i$. Every ℓ appearing in $(*)$ is then an off-diagonal neighbor: $\ell_{i+1,i} = e_i$, $\ell_{i-1,i} = e_{i-1}$, $\ell_{i,i-1} = e_{i-1}$, $\ell_{i,i+1} = e_i$. So

$$c_{ii} = e_i^2 - e_{i-1}^2 - e_{i-1}^2 + e_i^2 = 2(e_i^2 - e_{i-1}^2).$$

Case $j = i + 1$. Now $\ell_{i+1,i+1} = d_{i+1}$ and $\ell_{i,i} = d_i$, while $\ell_{i-1,i+1} = 0$ and $\ell_{i,i+2} = 0$ because Ł is tridiagonal. So $c_{i,i+1} = e_i d_{i+1} - e_i d_i$.

Case $j = i + 2$. Here $\ell_{i+1,i+2} = e_{i+1}$ and $\ell_{i,i+1} = e_i$, while $\ell_{i-1,i+2} = \ell_{i,i+3} = 0$. So

$$c_{i,i+2} = e_i e_{i+1} - 0 - e_{i+1}e_i + 0 = 0.$$

Case $j \ge i + 3$. Each of the four entries $\ell_{i+1,j}$, $\ell_{i-1,j}$, $\ell_{i,j-1}$, $\ell_{i,j+1}$ has its two indices differing by at least 2, so all four are 0 and $c_{ij} = 0$.

Hence $\mathbf{C}$ is symmetric tridiagonal with the stated entries, and equating $Ł'$ with $\mathbf{C}$ entry by entry gives Eq. 23.8.1. This proves the proposition. ∎

Read Eq. 23.8.1 for what it is. The off-diagonal entries feed the diagonal — mass e_i^2 flows from d_{i+1} up to d_i — and the diagonal drives the off-diagonal, each e_i growing or shrinking according to the sign of $d_{i+1} - d_i$. Summing the first family gives $\sum_i d_i' = 0$, the constancy of the trace, with the terms canceling in pairs. And an e_i that vanishes at some time has $e_i' = 0$ at that same time. It is tempting to read off that such an e_i stays 0 for ever — that the flow never re-couples two blocks which have already separated, the continuous shadow of deflation in Section 5 — but that is a statement about the *solutions* of the system, and getting it from the instantaneous one needs a uniqueness theorem for differential equations of the sort this section declined to assume above. Only the instantaneous statement is claimed here.

Example. (The 2×2 flow, twice)

Let $n = 2$, so $Ł = \left(\begin{smallmatrix} d_1 & e_1 \\ e_1 & d_2 \end{smallmatrix}\right)$ and Eq. 23.8.1 reads

$$d_1' = 2e_1^2, \qquad d_2' = -2e_1^2, \qquad e_1' = e_1(d_2 - d_1).$$

(a) Verify by hand that $\operatorname{tr} Ł$ and $\det Ł$ are constant along the flow.

(b) Solve the flow explicitly for $Ł(0) = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$.

Solution.

(a) $(\operatorname{tr} Ł)' = d_1' + d_2' = 2e_1^2 - 2e_1^2 = 0$. For the determinant,

$$(\det Ł)' = (d_1 d_2 - e_1^2)' = d_1' d_2 + d_1 d_2' - 2e_1 e_1',$$

by (D1) of Chapter 15 §06. Substituting,

$$2e_1^2 d_2 - 2d_1 e_1^2 - 2e_1^2(d_2 - d_1) = 0.$$

So both coefficients of $p_{Ł(t)}(x) = x^2 - (\operatorname{tr} Ł)x + \det Ł$ are constant, which is Theorem 23.8.1 for $n = 2$, got by hand.

(b) Put $u = e^{4t}$ and

$$d_1(t) = \frac{u-1}{u+1}, \qquad d_2(t) = -d_1(t), \qquad e_1(t) = \frac{2e^{2t}}{u+1}.$$

At $t = 0$, $u = 1$ gives $d_1 = 0$ and $e_1 = 1$, which is $Ł(0)$. Differentiating, with $u' = 4u$,

$$d_1' = \frac{4u(u+1) - (u-1)4u}{(u+1)^2} = \frac{8u}{(u+1)^2}, \qquad 2e_1^2 = \frac{8e^{4t}}{(u+1)^2} = \frac{8u}{(u+1)^2},$$

so the first equation holds; the second then holds because $d_2 = -d_1$. For the third,

$$e_1' = \frac{4e^{2t}(u+1) - 2e^{2t} \cdot 4u}{(u+1)^2} = \frac{4e^{2t}(1-u)}{(u+1)^2},$$

while $e_1(d_2 - d_1) = -2d_1 e_1 = -2 \cdot \frac{u-1}{u+1} \cdot \frac{2e^{2t}}{u+1}$, which is the same. Two checks: $d_1^2 + e_1^2 = \big((u-1)^2 + 4u\big)/(u+1)^2 = 1$, so $\det Ł(t) = -1$ for every t, matching $\det Ł(0) = -1$; and as $t \to \infty$, $d_1 \to 1$ and $e_1 \to 0$, so $Ł(t) \to \operatorname{diag}(1, -1)$. The flow sorts the eigenvalues ± 1 onto the diagonal, largest first.

The last sentence of that example is the whole point of the section. Sorting the eigenvalues onto the diagonal in decreasing order, with the off-diagonal entries dying away, is exactly what the QR algorithm does. The next theorem says the resemblance is an identity.

23.8.4 The QR algorithm is the Toda flow at integer times

One piece of algebra first. The skew-symmetric matrices and the upper triangular matrices fill $M_n(\mathbb{R})$ between them, without overlap.

Lemma 23.8.4 — Skew plus upper triangular, uniquely

Every $\mathbf{M} \in M_n(\mathbb{R})$ is $\mathbf{M} = \mathbf{K} + \mathbf{U}$ for exactly one skew-symmetric $\mathbf{K}$ and one upper triangular $\mathbf{U}$. If $\mathbf{M}$ is symmetric then $\mathbf{K} = \mathbf{M}_- - \mathbf{M}_+ = -\mathbf{B}(\mathbf{M})$.

Proof. Uniqueness. It suffices to show that a matrix $\mathbf{X}$ that is both skew-symmetric and upper triangular is 0. Its transpose $\mathbf{X}^\top = -\mathbf{X}$ is lower triangular and upper triangular at once, hence diagonal; so $\mathbf{X}$ is diagonal with $x_{ii} = -x_{ii}$, giving $\mathbf{X} = 0$. If $\mathbf{K}_1 + \mathbf{U}_1 = \mathbf{K}_2 + \mathbf{U}_2$ then $\mathbf{K}_1 - \mathbf{K}_2 = \mathbf{U}_2 - \mathbf{U}_1$ is such an $\mathbf{X}$.

Existence for symmetric $\mathbf{M}$, which is the only case we use. Put $\mathbf{K} = \mathbf{M}_- - \mathbf{M}_+$, skew-symmetric by the computation after Definition 23.8.2, and $\mathbf{U} = \mathbf{M} - \mathbf{K}$, whose strictly lower part is $\mathbf{M}_- - \mathbf{M}_- = 0$, so it is upper triangular. For a general $\mathbf{M}$, take $\mathbf{K} = \mathbf{M}_- - (\mathbf{M}_-)^\top$ and $\mathbf{U} = \mathbf{M} - \mathbf{K}$; the entries of $\mathbf{U}$ below the diagonal are $m_{ij} - m_{ij} = 0$ for $i > j$. This proves the lemma.

■

Theorem 23.8.5 — One QR Step Is One Unit of Toda Time

Let $Ł_0 \in M_n(\mathbb{R})$ be symmetric and let $\mathbf{A}^{(1)}, \mathbf{A}^{(2)}, \mathbf{A}^{(3)}, \dots$ be the unshifted QR iterates of Definition 23.5.1 started at $\mathbf{A}^{(1)} = e^{Ł_0}$, with the factorizations

$$\mathbf{A}^{(k)} = \mathbf{Q}^{(k)}\mathbf{R}^{(k)}, \qquad \mathbf{A}^{(k+1)} = \mathbf{R}^{(k)}\mathbf{Q}^{(k)} \qquad (k \geq 1)$$

normalized so that each $\mathbf{R}^{(k)}$ has positive diagonal entries, and write $\mathbf{W}_k = \mathbf{Q}^{(1)}\mathbf{Q}^{(2)}\cdots\mathbf{Q}^{(k)}$, with $\mathbf{W}_0 = \mathbf{I}$. Then for every $k \geq 0$:

(a) the factorizations exist and are unique, and $\mathbf{A}^{(k+1)} = \mathbf{W}_k^\top \mathbf{A}^{(1)} \mathbf{W}_k$;

(b) $\mathbf{W}_k$ is the orthogonal factor in the QR factorization of $e^{kŁ_0}$;

(c) $\mathbf{A}^{(k+1)} = e^{Ł_k}$, where $Ł_k = \mathbf{W}_k^\top Ł_0 \mathbf{W}_k$ is symmetric and has the same eigenvalues as $Ł_0$.

Idea. Each QR step is a similarity by the orthogonal factor, so after k steps the matrix has been conjugated by the accumulated product $\mathbf{W}_k$. Conjugating an exponential is exponentiating the conjugate, which turns the statement about $\mathbf{A}$ into a statement about Ł. The only thing left to identify is $\mathbf{W}_k$, and Section 5 has already done the work: Theorem 23.5.2 supplies the telescoping identity $(\mathbf{A}^{(1)})^k = \mathbf{W}_k\mathbf{R}^{(k)}\cdots\mathbf{R}^{(1)}$. A product of orthogonal matrices is orthogonal, a product of upper triangular matrices with positive diagonal is again one, so uniqueness of the QR factorization names $\mathbf{W}_k$ for us.

Proof. **Step 1: the factorizations exist and are unique.** By Theorem 9.9.4 (c), $\mathbf{A}^{(1)} = e^{Ł_0}$ is invertible, so its columns are independent and Theorem 10.8.1 applies, giving a unique $\mathbf{Q}^{(1)}$ with orthonormal columns — here square, hence orthogonal — and a unique upper triangular $\mathbf{R}^{(1)}$ with positive diagonal. Every $\mathbf{A}^{(k)}$ is similar to $\mathbf{A}^{(1)}$ by Proposition 23.5.1, hence invertible, so the same argument runs at every step. This positive-diagonal normalization is the choice Definition 23.5.1 deliberately left open, and it is the only ingredient here that Section 5 does not already supply.

Step 2: (a), and the telescoping identity. Every matrix here is real and each $\mathbf{Q}^{(k)}$ is orthogonal, so the conjugate transpose in Theorem 23.5.2 is a transpose. With $\mathbf{S}_k := \mathbf{R}^{(k)}\mathbf{R}^{(k-1)}\cdots\mathbf{R}^{(1)}$ and $\mathbf{S}_0 = \mathbf{I}$, that theorem — whose $\mathbf{U}_k$ and $\mathbf{T}_k$ are our $\mathbf{W}_k$ and $\mathbf{S}_k$ — gives, for every $k \geq 1$,

$$\mathbf{A}^{(k+1)} = \mathbf{W}_k^{\top}\,\mathbf{A}^{(1)}\,\mathbf{W}_k \qquad \text{and} \qquad (\mathbf{A}^{(1)})^k = \mathbf{W}_k\mathbf{S}_k,$$

and for $k = 0$ the two read $\mathbf{A}^{(1)} = \mathbf{A}^{(1)}$ and $\mathbf{I} = \mathbf{I}$, since $\mathbf{W}_0 = \mathbf{S}_0 = \mathbf{I}$. The first is (a).

Step 3: (b). Since $Ł_0$ commutes with itself, Theorem 9.9.4 (d) gives $(e^{Ł_0})^k = e^{kŁ_0}$, so $e^{kŁ_0} = \mathbf{W}_k\mathbf{S}_k$. Each $\mathbf{Q}^{(j)}$ is orthogonal, so $\mathbf{W}_k$ is orthogonal. Each $\mathbf{R}^{(j)}$ is upper triangular with positive diagonal, and a product of such matrices is upper triangular with diagonal entries the products of the diagonal entries, hence positive; so $\mathbf{S}_k$ is upper triangular with positive diagonal. By the uniqueness in Theorem 10.8.1, $\mathbf{W}_k\mathbf{S}_k$ **is** the QR factorization of $e^{kŁ_0}$.

Step 4: (c). $\mathbf{W}_k$ is orthogonal, so $\mathbf{W}_k^{\top} = \mathbf{W}_k^{-1}$, and Theorem 9.9.4 (a) gives

$$\mathbf{A}^{(k+1)} = \mathbf{W}_k^{-1}e^{Ł_0}\mathbf{W}_k = e^{\mathbf{W}_k^{-1}Ł_0\mathbf{W}_k} = e^{Ł_k}.$$

Finally $Ł_k^{\top} = \mathbf{W}_k^{\top}Ł_0^{\top}\mathbf{W}_k = Ł_k$, and $Ł_k$ is similar to $Ł_0$, so the two have the same characteristic polynomial (Theorem 6.10.3) and hence the same eigenvalues. This proves the theorem.

■

So the QR algorithm, applied to the exponential of a symmetric matrix, is a sequence of orthogonal conjugations of $Ł_0$ whose k-th term is read off the QR factorization of $e^{kŁ_0}$. That last description makes sense for every real t, not only for integers, and it is the missing curve.

Remark. **The continuous statement, and the one thing in it we do not prove.** For $t \in \mathbb{R}$ let $e^{tŁ_0} = \mathbf{Q}(t)\mathbf{R}(t)$ be the QR factorization with $\mathbf{R}(t)$ of positive diagonal, and put $Ł(t) = \mathbf{Q}(t)^{\top}Ł_0\mathbf{Q}(t)$. By Theorem 23.8.5 (b) and (c), $\mathbf{Q}(k) = \mathbf{W}_k$ and $Ł(k) = Ł_k$, so this curve passes through the QR iterates at the integer times. **Granting that $t \mapsto \mathbf{Q}(t)$ is differentiable** — it is, because the Gram–Schmidt formulas express its entries through arithmetic and square roots of positive quantities, but that is a fact of analysis this book has not set up — the curve satisfies the Lax equation $Ł' = [\mathbf{B}(Ł), Ł]$. Here is the derivation. Differentiating $e^{tŁ_0} = \mathbf{QR}$ with Theorem 9.9.4 (b) and Lemma 15.6.4 gives $Ł_0\mathbf{QR} = \mathbf{Q}'\mathbf{R} + \mathbf{QR}'$; multiplying by $\mathbf{R}^{-1}$ on the right and $\mathbf{Q}^{\top}$ on the left,

$$Ł(t) = \mathbf{Q}^{\top}Ł_0\mathbf{Q} = \mathbf{Q}^{\top}\mathbf{Q}' + \mathbf{R}'\mathbf{R}^{-1}.$$

Now $\mathbf{Q}^{\top}\mathbf{Q} = \mathbf{I}$ differentiates to $(\mathbf{Q}')^{\top}\mathbf{Q} + \mathbf{Q}^{\top}\mathbf{Q}' = 0$, so $\mathbf{Q}^{\top}\mathbf{Q}'$ is skew-symmetric, while $\mathbf{R}'\mathbf{R}^{-1}$ is upper triangular. By Lemma 23.8.4 the splitting is unique, so $\mathbf{Q}^{\top}\mathbf{Q}' = -\mathbf{B}(Ł(t))$. Differentiating $Ł = \mathbf{Q}^{\top}Ł_0\mathbf{Q}$, inserting $\mathbf{QQ}^{\top} = \mathbf{I}$ in each term and using

$(\mathbf{Q}')^\top\mathbf{Q} = -\mathbf{Q}^\top\mathbf{Q}'$,

$$Ł' = (\mathbf{Q}')^\top Ł_0\mathbf{Q} + \mathbf{Q}^\top Ł_0\mathbf{Q}' = -(\mathbf{Q}^\top\mathbf{Q}')Ł + Ł(\mathbf{Q}^\top\mathbf{Q}') = [\mathbf{B}(Ł), Ł].$$

That is a Lax equation, and $Ł_0$ was only assumed symmetric. It is the *Toda* flow of Definition 23.8.2 when $Ł(t)$ is in addition symmetric **tridiagonal**, which the definition demands, and it is so whenever $Ł_0$ is. Here is why. Since $\mathbf{R}(t)$ is upper triangular and invertible, the span of the first j columns of $\mathbf{Q}(t)$ is the span of the first j columns of $e^{tŁ_0}$, namely $e^{tŁ_0}\,\mathrm{span}(\mathbf{e}_1,\dots,\mathbf{e}_j)$. A tridiagonal $Ł_0$ carries $\mathrm{span}(\mathbf{e}_1,\dots,\mathbf{e}_j)$ into $\mathrm{span}(\mathbf{e}_1,\dots,\mathbf{e}_{j+1})$, and it commutes with $e^{tŁ_0}$ (Theorem 9.9.4 (b)), so it carries the span of the first j columns of $\mathbf{Q}(t)$ into the span of the first $j+1$. The i-th column of $\mathbf{Q}(t)$ is orthogonal to that span for $i > j+1$, so the (i,j) entry of $Ł(t) = \mathbf{Q}^\top Ł_0\mathbf{Q}$ vanishes there: nothing below the subdiagonal, and symmetric, hence tridiagonal. For such an $Ł_0$ the curve is the Toda flow, Proposition 23.8.3 puts it in the coordinates Eq. 23.8.1, and, modulo that one differentiability, **the QR algorithm is the time-one map of the Toda flow**. The discrete half of the statement, Theorem 23.8.5, rests on nothing unproved; the continuous half is flagged here and nothing later depends on it.

Warning. **The interpolation is of Ł, not of A, and it needs the starting matrix to be an exponential.** Theorem 23.8.5 starts from $\mathbf{A}^{(1)} = e^{Ł_0}$, so it says nothing directly about the QR algorithm run on an arbitrary matrix. The matrices it does cover are exactly the symmetric positive definite ones. On the one hand $e^{Ł_0} = \mathbf{Q}e^{\mathbf{D}}\mathbf{Q}^\top$ is symmetric with positive eigenvalues e^{λ_i}, writing $Ł_0 = \mathbf{Q}\mathbf{D}\mathbf{Q}^\top$ by Corollary 11.5.2 and using Theorem 9.9.4 (a) together with Corollary 9.9.5; on the other, a symmetric $\mathbf{A} \succ 0$ with eigenvalues $\mu_i > 0$ is $e^{Ł_0}$ for the symmetric $Ł_0 = \mathbf{Q}\,\mathrm{diag}(\log\mu_1,\dots,\log\mu_n)\mathbf{Q}^\top$, the logarithm being the one built in Chapter 17 §11 (Lemma 17.11.1). A symmetric matrix with a negative eigenvalue is therefore out of reach. The right reading is not "QR is Toda" but "QR on $e^{Ł_0}$ is Toda on $Ł_0$".

23.8.5 What this buys

Nothing in this section makes a computation faster. What it does is change what the QR algorithm *is*. As an algorithm it is a rule: factor, multiply back, repeat, and hope the subdiagonal shrinks. As a flow it is a curve in a bounded set — every entry of a symmetric matrix is at most its largest eigenvalue in absolute value, and the spectrum is frozen — and the questions one asks about it change accordingly. Why does the largest eigenvalue surface at the top left? Because $d_1' = 2e_1^2 \geq 0$ at all times. Why do the off-diagonal entries die away geometrically once the diagonal has almost settled? Because $e_i' = e_i(d_{i+1} - d_i)$, which near a diagonal limit is decay at the rate of the gap $d_i - d_{i+1}$ — the same eigenvalue gap that governs the QR algorithm's rate in Section 5. Neither reading is a proof, and neither is visible at all in the discrete language.

That is the general lesson, and it is worth naming as one of this chapter's moves: an algorithm and a differential equation can be the same object at two resolutions, and which resolution to use is a choice. Similar correspondences are known for other iterations, including the shifted QR algorithm; none of them is proved here. The subject they belong to is the theory of integrable systems, and it is the one place where this computational chapter touches pure mathematics.

23.8.6 Exercises

23.8.6.1 A. Check your understanding

Exercise A1.

(a) Define a Lax pair, and say which of the two functions is required to be differentiable.

(b) State Theorem 23.8.1, and name the two results from earlier chapters its proof uses.

(c) Determine whether the following statement is correct, and justify your answer: if $Ł' = [\mathbf{B}, Ł]$ then $Ł(t) = Ł(0)$ for all t.

(d) Explain in one sentence why the proof of Theorem 23.8.1 does not construct the conjugating matrix $\mathbf{S}(t)$.

(e) Write down the Toda equations Eq. 23.8.1 for $n = 3$, and check that the sum of the three diagonal equations is 0.

Solution.

(a) A pair $Ł, \mathbf{B} \colon I \to M_n(\mathbb{C})$ with $Ł$ differentiable and $Ł'(t) = \mathbf{B}(t)Ł(t) - Ł(t)\mathbf{B}(t)$ for all $t \in I$. Only $Ł$ must be differentiable.

(b) The characteristic polynomial of $Ł(t)$ is independent of t. The proof uses Jacobi's formula (Theorem 15.6.6) and the adjugate identity (Theorem 6.6.2), together with $\operatorname{tr}(\mathbf{XY}) = \operatorname{tr}(\mathbf{YX})$ (Theorem 0.9.6 (3)).

(c) Incorrect. Example (A curve of matrices with a frozen spectrum) has $Ł(t) = \left(\begin{smallmatrix} t & -t^2 \\ 1 & -t \end{smallmatrix}\right)$, which is non-constant while its characteristic polynomial x^2 is constant. Isospectral is much weaker than constant.

(d) Because for a $\mathbf{B}$ depending on t that matrix is the solution of a linear differential equation with variable coefficients, whose existence this book does not prove; differentiating the determinant avoids needing it at all.

(e) With $e_0 = e_3 = 0$:

$$d_1' = 2e_1^2, \quad d_2' = 2(e_2^2 - e_1^2), \quad d_3' = -2e_2^2,$$

$$e_1' = e_1(d_2 - d_1), \quad e_2' = e_2(d_3 - d_2).$$

The three diagonal right-hand sides sum to $2e_1^2 + 2e_2^2 - 2e_1^2 - 2e_2^2 = 0$, which is the constancy of the trace.

23.8.6.2 B. Practice

Exercise B1: A Lax pair verified.

Let $\mathbf{B} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $Ł(t) = \begin{pmatrix} t & -t^2 \\ 1 & -t \end{pmatrix}$.

(a) Verify directly that $Ł'(t) = [\mathbf{B}, Ł(t)]$.

(b) Compute $p_{Ł(t)}$ and confirm Theorem 23.8.1 in this case.

(c) Determine whether $Ł(t)$ and $Ł(0)$ are similar for every t, and exhibit the similarity.

Solution.

(a) $Ł'(t) = \left(\begin{smallmatrix} 1 & -2t \\ 0 & -1 \end{smallmatrix}\right)$. On the other side,

$$\mathbf{B}Ł = \begin{pmatrix} 1 & -t \\ 0 & 0 \end{pmatrix}, \qquad Ł\mathbf{B} = \begin{pmatrix} 0 & t \\ 0 & 1 \end{pmatrix},$$

so $[\mathbf{B}, Ł] = \left(\begin{smallmatrix} 1 & -2t \\ 0 & -1 \end{smallmatrix}\right) = Ł'(t)$.

(b) $\operatorname{tr} Ł(t) = t - t = 0$ and $\det Ł(t) = -t^2 - (-t^2) = 0$, so $p_{Ł(t)}(x) = x^2$ for every t. The spectrum is $\{0\}$ at all times.

(c) Yes. Since $\mathbf{B}$ is constant, Corollary 23.8.2 applies, and $e^{t\mathbf{B}} = \mathbf{I} + t\mathbf{B}$ because $\mathbf{B}^2 = 0$. So

$$Ł(t) = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix} Ł(0) \begin{pmatrix} 1 & -t \\ 0 & 1 \end{pmatrix}, \qquad Ł(0) = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix},$$

which one checks by multiplying out. (Similarity is also forced by (b) alone here: both matrices are non-zero and nilpotent of size 2, hence both similar to $\mathbf{J}_2(0)$.)

Exercise B2: The bracket by hand.

Let

$$Ł = \begin{pmatrix} 1 & 2 & 0 \\ 2 & 3 & 1 \\ 0 & 1 & -1 \end{pmatrix}.$$

Compute $\mathbf{B}(Ł)$ and $[\mathbf{B}(Ł), Ł]$ directly, and check the answer against Proposition 23.8.3.

Solution. Here $d = (1, 3, -1)$ and $e = (2, 1)$. The strictly upper and lower parts give

$$\mathbf{B}(Ł) = \begin{pmatrix} 0 & 2 & 0 \\ -2 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix}.$$

Multiplying,

$$\mathbf{B}(Ł)Ł = \begin{pmatrix} 4 & 6 & 2 \\ -2 & -3 & -1 \\ -2 & -3 & -1 \end{pmatrix}, \qquad Ł\mathbf{B}(Ł) = \begin{pmatrix} -4 & 2 & 2 \\ -6 & 3 & 3 \\ -2 & 1 & 1 \end{pmatrix},$$

so

$$[\mathbf{B}(Ł), Ł] = \begin{pmatrix} 8 & 4 & 0 \\ 4 & -6 & -4 \\ 0 & -4 & -2 \end{pmatrix}.$$

Against Proposition 23.8.3: $2(e_1^2 - e_0^2) = 2 \cdot 4 = 8$; $2(e_2^2 - e_1^2) = 2(1 - 4) = -6$; $2(e_3^2 - e_2^2) = -2$; $e_1(d_2 - d_1) = 2(3 - 1) = 4$; $e_2(d_3 - d_2) = 1(-1 - 3) = -4$. All five agree, the matrix is symmetric tridiagonal, and its trace is $8 - 6 - 2 = 0$, as it must be.

Exercise B3: One QR step on an exponential.

Let $Ł_0 = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ and $\mathbf{A}^{(1)} = e^{Ł_0}$.

(a) Show that $e^{tŁ_0} = \left(\begin{smallmatrix} c(t) & s(t) \\ s(t) & c(t) \end{smallmatrix}\right)$ with $c(t) = \tfrac{1}{2}(e^t + e^{-t})$ and $s(t) = \tfrac{1}{2}(e^t - e^{-t})$.

(b) Find the QR factorization of $e^{tŁ_0}$ with positive diagonal, and hence $Ł(t) = \mathbf{Q}(t)^\top Ł_0 \mathbf{Q}(t)$.

(c) Compare your $Ł(1)$ with Example (The 2×2 flow, twice) (b).

Solution.

(a) $Ł_0^2 = \mathbf{I}$, so $Ł_0^{2m} = \mathbf{I}$ and $Ł_0^{2m+1} = Ł_0$. Splitting Definition 9.9.2 into even and odd terms,

$$e^{tŁ_0} = \Big(\sum_{m \ge 0} \frac{t^{2m}}{(2m)!}\Big)\mathbf{I} + \Big(\sum_{m \ge 0} \frac{t^{2m+1}}{(2m+1)!}\Big)Ł_0,$$

and the two scalar series are the even and odd halves of $e^t = \sum_j t^j/j!$, namely $c(t)$ and $s(t)$ by fact (A1) of Chapter 9 §09.

(b) Write $\rho = (c^2 + s^2)^{1/2} > 0$. Gram–Schmidt on the columns, as in Theorem 10.8.1: the first column (c, s) normalizes to $\mathbf{q}_1 = \rho^{-1}(c, s)$; the second column (s, c) has $\langle (s, c), \mathbf{q}_1 \rangle = 2cs/\rho$, and

$$(s, c) - \frac{2cs}{\rho^2}(c, s) = \frac{c^2 - s^2}{\rho^2}(-s, c) = \frac{1}{\rho^2}(-s, c),$$

because $c^2 - s^2 = 1$. That vector has length $1/\rho$, so $\mathbf{q}_2 = \rho^{-1}(-s, c)$. Hence $\mathbf{Q}(t) = \rho^{-1}\left(\begin{smallmatrix} c & -s \\ s & c \end{smallmatrix}\right)$, whose determinant is 1, and $\mathbf{R}(t) = \mathbf{Q}(t)^\top e^{tŁ_0}$ has positive diagonal. Then

$$Ł(t) = \mathbf{Q}^\top Ł_0 \mathbf{Q} = \frac{1}{\rho^2}\begin{pmatrix} 2cs & 1 \\ 1 & -2cs \end{pmatrix}.$$

Since $\rho^2 = c^2 + s^2 = \tfrac{1}{2}(e^{2t} + e^{-2t})$ and $2cs = \tfrac{1}{2}(e^{2t} - e^{-2t})$, multiplying numerator and denominator by $2e^{2t}$ gives

$$Ł(t) = \begin{pmatrix} \dfrac{e^{4t} - 1}{e^{4t} + 1} & \dfrac{2e^{2t}}{e^{4t} + 1} \\[2ex] \dfrac{2e^{2t}}{e^{4t} + 1} & -\dfrac{e^{4t} - 1}{e^{4t} + 1} \end{pmatrix}.$$

(c) This is exactly the solution written down in Example (The 2×2 flow, twice) (b). At $t = 1$ it is $d_1 = (e^4 - 1)/(e^4 + 1) \approx 0.9640$ and $e_1 = 2e^2/(e^4 + 1) \approx 0.2658$. One QR step on $e^{Ł_0}$ has moved Ł one unit of Toda time, and the off-diagonal entry has already fallen from 1 to about 0.27.

23.8.6.3 C. Going deeper

Exercise C1: The power sums are constants of the motion.

Let $(Ł, \mathbf{B})$ be a Lax pair on I.

(a) Prove that $t \mapsto \operatorname{tr}\big(Ł(t)^m\big)$ is constant for every integer $m \ge 1$. *Hint: the product*

rule, then Theorem 0.9.6 (3).

(b) Deduce, for $n = 2$, that the characteristic polynomial of $Ł(t)$ is constant, without using Theorem 23.8.1.

Solution.

(a) By Lemma 15.6.4 and induction, $t \mapsto Ł(t)^m$ is differentiable with

$$(Ł^m)' = \sum_{j=0}^{m-1} Ł^j\, Ł'\, Ł^{m-1-j}.$$

The trace is linear (Theorem 0.9.6 (1)) and unchanged by a cyclic shift (Theorem 0.9.6 (3)), so each summand contributes $\operatorname{tr}(Ł^{m-1}Ł')$, and

$$\big(\operatorname{tr} Ł^m\big)' = m\,\operatorname{tr}\big(Ł^{m-1}Ł'\big) = m\,\operatorname{tr}\big(Ł^{m-1}(\mathbf{B}Ł - Ł\mathbf{B})\big).$$

Now $\operatorname{tr}(Ł^{m-1}\mathbf{B}Ł) = \operatorname{tr}(Ł Ł^{m-1}\mathbf{B}) = \operatorname{tr}(Ł^m\mathbf{B})$ by a cyclic shift, and $\operatorname{tr}(Ł^{m-1}Ł\mathbf{B}) = \operatorname{tr}(Ł^m\mathbf{B})$ as well, so the bracket contributes 0. By fact (A6) of Chapter 15's introduction the function is constant on I.

(b) For $n = 2$, $p_{Ł(t)}(x) = x^2 - \tau x + \delta$ with $\tau = \operatorname{tr} Ł(t)$ and $\delta = \det Ł(t)$. By Cayley–Hamilton (Theorem 8.6.1), $Ł^2 - \tau Ł + \delta\mathbf{I} = 0$; taking traces gives $\operatorname{tr}(Ł^2) - \tau^2 + 2\delta = 0$, that is

$$\delta = \tfrac{1}{2}\big(\tau^2 - \operatorname{tr}(Ł^2)\big).$$

Part (a) with $m = 1$ makes τ constant and with $m = 2$ makes $\operatorname{tr}(Ł^2)$ constant, so δ is constant too. Hence $p_{Ł(t)}$ is constant.

Exercise C2: How far B is from being determined.

Let $(Ł, \mathbf{B})$ be a Lax pair on I and let $\mathbf{C}\colon I \to M_n(\mathbb{C})$ satisfy $[\mathbf{C}(t), Ł(t)] = 0$ for every t.

(a) Prove that $(Ł, \mathbf{B} + \mathbf{C})$ is also a Lax pair.

(b) Give an example with $\mathbf{C} \neq 0$, and conclude that a Lax equation does not determine $\mathbf{B}$.

(c) Prove, using Lemma 23.8.4, that there is nevertheless **exactly one** skew-symmetric $\mathbf{B}$ for which $\mathbf{B}+$ (upper triangular) equals a given symmetric $Ł$ — that is, the $\mathbf{B}(Ł)$ of Definition 23.8.2 is the only natural candidate once "skew-symmetric" and "upper triangular" are the two slots.

Solution.

(a) $[\mathbf{B} + \mathbf{C}, Ł] = [\mathbf{B}, Ł] + [\mathbf{C}, Ł] = [\mathbf{B}, Ł] + 0 = Ł'$.

(b) Take $\mathbf{C}(t) = c\,\mathbf{I}$ for any scalar $c \neq 0$, or $\mathbf{C}(t) = q(Ł(t))$ for any polynomial q, since a polynomial in $Ł$ commutes with $Ł$. So $\mathbf{B}$ can always be altered by a multiple of $\mathbf{I}$ without changing the flow, and the Lax equation determines $\mathbf{B}$ at most up to the commutant of $Ł$.

(c) Lemma 23.8.4 says $Ł = \mathbf{K} + \mathbf{U}$ for exactly one skew-symmetric $\mathbf{K}$ and one upper triangular $\mathbf{U}$, and computes $\mathbf{K} = Ł_- - Ł_+ = -\mathbf{B}(Ł)$ for symmetric $Ł$. So the pair of slots (skew, upper triangular) picks out $\mathbf{B}(Ł)$ uniquely, up to the sign

convention, and the remaining freedom found in (a) and (b) is freedom in a *different* decomposition, not in this one.

Exercise C3: Symmetry constrains B.

Let $(Ł, \mathbf{B})$ be a Lax pair of real matrices on I with $Ł(t)$ symmetric for every t.

(a) Prove that $[\mathbf{B}(t) + \mathbf{B}(t)^\top,\ Ł(t)] = 0$ for every t.

(b) Deduce that $\big(Ł, \frac{1}{2}(\mathbf{B} - \mathbf{B}^\top)\big)$ is also a Lax pair, so that $\mathbf{B}$ may always be taken skew-symmetric.

(c) Determine whether the Toda $\mathbf{B}(Ł)$ of Definition 23.8.2 satisfies the hypothesis of (a). Justify your answer.

Solution.

(a) Transposing $Ł' = \mathbf{B}Ł - Ł\mathbf{B}$ and using $Ł^\top = Ł$ — so that $(Ł')^\top = (Ł^\top)' = Ł'$, differentiation being entrywise — gives

$$Ł' = (Ł')^\top = Ł^\top\mathbf{B}^\top - \mathbf{B}^\top Ł^\top = Ł\mathbf{B}^\top - \mathbf{B}^\top Ł = -[\mathbf{B}^\top, Ł].$$

Adding this to $Ł' = [\mathbf{B}, Ł]$ gives $2Ł' = [\mathbf{B}, Ł] - [\mathbf{B}^\top, Ł]$, while subtracting gives $0 = [\mathbf{B}, Ł] + [\mathbf{B}^\top, Ł] = [\mathbf{B} + \mathbf{B}^\top, Ł]$.

(b) Put $\mathbf{C} = -\frac{1}{2}(\mathbf{B} + \mathbf{B}^\top)$. By (a), $[\mathbf{B} + \mathbf{B}^\top, Ł] = 0$, so $[\mathbf{C}, Ł] = 0$, and Exercise (C2: How far **B** is from being determined) (a) says $(Ł, \mathbf{B} + \mathbf{C})$ is a Lax pair. But $\mathbf{B} + \mathbf{C} = \mathbf{B} - \frac{1}{2}(\mathbf{B} + \mathbf{B}^\top) = \frac{1}{2}(\mathbf{B} - \mathbf{B}^\top)$, which is skew-symmetric. So the skew part of $\mathbf{B}$ already drives the flow, and the symmetric part is inert.

(c) Yes, and trivially: $\mathbf{B}(Ł)$ is skew-symmetric for symmetric $Ł$, so $\mathbf{B}(Ł) + \mathbf{B}(Ł)^\top = 0$, which commutes with everything. Part (b) says that this is not a lucky feature of the Toda choice but the normal form of any Lax pair with symmetric $Ł$.

23.9 Vibrations

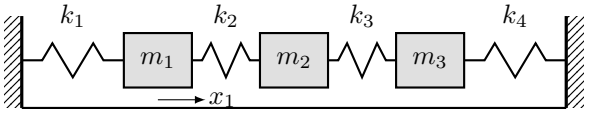
Chapter 12 §04 diagonalized two forms at once and then said, in one sentence, what the theorem was for: for a vibrating structure one matrix is the mass matrix, the other the stiffness matrix, the generalized eigenvalues are the squared natural frequencies, and the eigenvectors are the normal modes. This section turns that sentence into a theorem and reads off its consequences. Everything in it is linear algebra already proved, applied to one physical model; the model is the only new ingredient, and it is stated as a model, not derived.

Throughout, the field is $\mathbb{R}$, and $n \geq 1$ is the number of moving masses.

A note on the letter K. In this section $\mathbf{K}$ is the stiffness matrix. Chapter 18 §09's second-difference matrix always carries its size as a subscript, $\mathbf{K}_n$, and it will appear below as exactly that; the two never collide.

23.9.1 A chain of masses and springs

Picture n carts on a line, joined to each other and to two fixed walls by springs. Each cart is at rest in some position, and we track only its **displacement** from that position, so that the rest state is the zero vector. The question is what the system does when it is pushed and released.



Two physical laws describe what happens, and both are assumptions, not theorems of this book. We give them a name and numbered clauses, so that the steps below can say which one they are using.

Definition 23.9.1 — The mass–spring model (P1) **(Newton's second law.)** A mass $m_i > 0$ whose displacement is $x_i(t)$ obeys $m_i x_i''(t) = f_i(t)$, where f_i is the total force on it.

(P2) **(Hooke's law.)** A spring of **stiffness** $k \geq 0$ whose two ends have moved by a and b pulls its ends together with force $k(b-a)$ acting on the end at a, and $-k(b-a)$ on the end at b. A wall is an end whose displacement is 0. A spring of stiffness 0 exerts no force whatever, so it is the same thing as no spring at all.

Hooke's law is an idealization: real springs obey it only for small displacements, and every real system also loses energy. We assume both laws exactly, and everything below is a theorem about that idealization; the energy loss reappears as the non-example below.

Take the chain in the picture: three masses m_1, m_2, m_3 and four springs $k_1, \dots, k_4$, with k_1 joining the left wall to mass 1 and k_4 joining mass 3 to the right wall. The force on mass 1 comes from the springs on either side of it, so by (P1) and (P2) of Definition 23.9.1,

$$\begin{aligned} m_1 x_1'' &= -k_1 x_1 + k_2(x_2 - x_1), \\ m_2 x_2'' &= -k_2(x_2 - x_1) + k_3(x_3 - x_2), \\ m_3 x_3'' &= -k_3(x_3 - x_2) - k_4 x_3. \end{aligned}$$

Collecting the coefficients of x_1, x_2, x_3 on the right and moving the sign out front, this is $\mathbf{M}\mathbf{x}'' = -\mathbf{K}\mathbf{x}$ with

$$\mathbf{M} = \begin{pmatrix} m_1 & & \\ & m_2 & \\ & & m_3 \end{pmatrix}, \quad \mathbf{K} = \begin{pmatrix} k_1+k_2 & -k_2 & 0 \\ -k_2 & k_2+k_3 & -k_3 \\ 0 & -k_3 & k_3+k_4 \end{pmatrix}.$$

The matrix $\mathbf{M}$ is diagonal with positive entries, hence positive definite. The matrix $\mathbf{K}$ is symmetric, and it is positive semidefinite for a reason worth isolating, so we record the general shape first.

A mass–spring system is a pair of forms: one that measures inertia and one that measures the price of a deformation.

Definition 23.9.2 — Mass–spring system

A **mass–spring system** with n degrees of freedom is a pair of real symmetric matrices $\mathbf{M}, \mathbf{K} \in M_n(\mathbb{R})$ with $\mathbf{M} \succ 0$ and $\mathbf{K} \succeq 0$, called the **mass matrix** and the **stiffness matrix**. A **motion** of the system is a twice-differentiable function $\mathbf{x}\colon \mathbb{R} \to \mathbb{R}^n$ with

$$\mathbf{M}\mathbf{x}''(t) = -\mathbf{K}\mathbf{x}(t) \qquad \text{for every } t \in \mathbb{R}. \tag{23.9.1}$$

The same equation is read for a function $\mathbf{x}\colon \mathbb{R} \to \mathbb{C}^n$ whenever a complex trial solution is convenient; a **motion** without qualification is real.

In words: $\mathbf{M} \succ 0$ says every direction of motion costs some inertia, so no coordinate is massless; $\mathbf{K} \succeq 0$ says no deformation releases energy, so the rest state $\mathbf{x} = \mathbf{0}$ is not a hilltop. The quantities $\frac{1}{2}(\mathbf{x}')^{\top}\mathbf{M}\mathbf{x}'$ and $\frac{1}{2}\mathbf{x}^{\top}\mathbf{K}\mathbf{x}$ are what the model calls the kinetic and potential energy of the state $(\mathbf{x}, \mathbf{x}')$ — a third physical identification, on the same footing as (P1) and (P2) of Definition 23.9.1 and used nowhere in a proof — and the two definiteness hypotheses say exactly that the first is positive and the second non-negative away from rest.

For the chain, positive semidefiniteness of $\mathbf{K}$ is a factorization. Number the springs $1, \dots, n+1$ from left to right and let $\mathbf{B} \in M_{(n+1)\times n}(\mathbb{R})$ be the matrix whose row e records how much spring e is stretched: for the chain above,

$$\mathbf{B} = \begin{pmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 0 & -1 & 1 \\ 0 & 0 & -1 \end{pmatrix}, \qquad \mathbf{K} = \mathbf{B}^{\top}\mathbf{D}_k\mathbf{B},$$

where $\mathbf{D}_k = \operatorname{diag}(k_1, \dots, k_{n+1})$. Multiplying out confirms the second identity entry by entry. Consequently

$$\mathbf{x}^{\top}\mathbf{K}\mathbf{x} = (\mathbf{B}\mathbf{x})^{\top}\mathbf{D}_k(\mathbf{B}\mathbf{x}) = \sum_{e} k_e\,(\mathbf{B}\mathbf{x})_e^2 \;\geq\; 0,$$

a sum of squares weighted by the stiffnesses: the potential energy stored in the springs. Together with $\mathbf{K}^{\top} = \mathbf{K}$ this is Definition 12.1.1, so $\mathbf{K} \succeq 0$ with no computation of eigenvalues. (The matrix $\mathbf{B}$ is, up to a transpose and the deletion of the two wall rows, the incidence matrix of Chapter 2 §07, Definition 2.7.1, of the chain together with a choice of orientation for each spring: the orientation is what fixes the sign pattern of the rows, and it is what Definition 2.7.1 records as the head and the tail of an edge. The last section of this chapter takes that observation seriously.)

Three instances, simplest first.

Example. (Three systems)

(a) $n = 1$: one mass m between two walls with springs k_1, k_2. Then $\mathbf{M} = (m)$ and $\mathbf{K} = (k_1 + k_2)$, both 1×1.

(b) $n = 3$ with all masses equal to m and all four stiffnesses equal to k. Then $\mathbf{M} = m\mathbf{I}_3$ and $\mathbf{K} = k\mathbf{K}_3$, where $\mathbf{K}_3$ is the second-difference matrix met in Proposition 18.9.6.

(c) The **free** chain: the same three masses joined to each other by k_2, k_3 but with **no**

walls, so $k_1 = k_4 = 0$. Then $\mathbf{K}$ is still symmetric and still $\mathbf{B}^\top \mathbf{D}_k \mathbf{B}$, hence $\succeq 0$, but now $\mathbf{K}\mathbf{1} = \mathbf{0}$: sliding the whole chain sideways stretches nothing.

Case (c) is the degenerate one, and it is not a pathology to be excluded: it is why the definition asks only for $\mathbf{K} \succeq 0$. A system with a direction of zero stiffness has a motion that is not a vibration at all, and the theorem below will produce it.

Change one clause and the definition stops describing this situation. If a cart also feels friction proportional to its velocity, the equation becomes $\mathbf{M}\mathbf{x}'' = -\mathbf{K}\mathbf{x} - \mathbf{C}\mathbf{x}'$ with $\mathbf{C} \succeq 0$ the damping matrix; the right-hand side is no longer a function of $\mathbf{x}$ alone, Eq. 23.9.1 fails, and the analysis of this section does not apply to it. The models differ in exactly one term, and everything below uses the absence of that term.

Warning. **The natural frequencies are not the eigenvalues of K divided by the eigenvalues of M.** Take $\mathbf{M} = \operatorname{diag}(1, 4)$ and $\mathbf{K} = \left(\begin{smallmatrix} 2 & -1 \\ -1 & 2 \end{smallmatrix}\right)$. The eigenvalues of $\mathbf{K}$ are 3 and 1, those of $\mathbf{M}$ are 4 and 1, so the four available quotients are $3, 3/4, 1$ and $1/4$. The squared natural frequencies, computed from $\det(\mathbf{K} - \lambda\mathbf{M}) = 4\lambda^2 - 10\lambda + 3$, are

$$\lambda = \tfrac{5 \pm \sqrt{13}}{4} \approx 2.151,\ 0.349,$$

and neither is on the list. Mass and stiffness interact through their eigenvectors, not only through their eigenvalues; only when $\mathbf{M}$ is a scalar multiple of $\mathbf{I}$ does the naive rule hold.

23.9.2 Normal modes

A motion of one mass on one spring is a single oscillation. The hope is that a motion of n masses is a superposition of n such oscillations, each with its own frequency and its own shape. That hope is exactly Theorem 12.4.1, and the only thing needed before it is the one-dimensional case.

Lemma 23.9.1 — The scalar oscillator

Let $\omega \geq 0$ and let $y\colon \mathbb{R} \to \mathbb{C}$ be twice differentiable with $y'' = -\omega^2 y$. If $\omega > 0$, then

$$y(t) = y(0)\cos\omega t + \frac{y'(0)}{\omega}\sin\omega t$$

for every t; if $\omega = 0$, then $y(t) = y(0) + y'(0)t$. Conversely every function of these two shapes satisfies $y'' = -\omega^2 y$.

Idea. A second-order scalar equation is a first-order system in the variable (y, y'), which is the translation of Example (A Second-Order Equation with a Repeated Root). Once it is a system, Theorem 9.9.6 supplies both existence and, what we actually want, uniqueness: two solutions with the same value and the same derivative at 0 are the same function.

Proof. Put $\mathbf{N} = \left(\begin{smallmatrix} 0 & 1 \\ -\omega^2 & 0 \end{smallmatrix}\right)$ and $\mathbf{u} = (y, y')$. Then $\mathbf{u}' = (y', y'') = (y', -\omega^2 y) = \mathbf{N}\mathbf{u}$, and conversely a differentiable $\mathbf{u} = (u_1, u_2)$ with $\mathbf{u}' = \mathbf{N}\mathbf{u}$ has $u_2 = u_1'$ and $u_1'' = -\omega^2 u_1$. By Theorem 9.9.6 there is exactly one differentiable $\mathbf{u}\colon \mathbb{R} \to \mathbb{C}^2$ with $\mathbf{u}' = \mathbf{N}\mathbf{u}$ and a given value at 0.

For the converse half, $(e^{zt})' = ze^{zt}$ for $z \in \mathbb{C}$, which is the 1×1 case of Theorem 9.9.4

(b); applying it twice, $e^{\pm i\omega t}$ satisfies $y'' = -\omega^2 y$. Euler's formula — fact (A1) of Chapter 9 §09 — writes $\cos\omega t$ and $\sin\omega t$ as the combinations $\frac{1}{2}(e^{i\omega t}+e^{-i\omega t})$ and $\frac{1}{2i}(e^{i\omega t}-e^{-i\omega t})$, so both satisfy it too, as does every linear combination of them; and for $\omega = 0$ the functions 1 and t satisfy $y'' = 0$.

Now let y be any solution and let z be the function displayed in the statement. By the previous paragraph z is a solution. Differentiating, $z(0) = y(0)$ and $z'(0) = y'(0)$ in both cases, the case $\omega > 0$ using $(\sin\omega t)' = \omega\cos\omega t$ at $t = 0$. So (y, y') and (z, z') solve $\mathbf{u}' = \mathbf{N}\mathbf{u}$ with the same value at 0, and uniqueness gives $y = z$. This proves the lemma.

■

Now the main theorem. Read the substitution in part (a) as a question: is there a motion in which every mass moves with the *same* time dependence, so that the shape of the deformation never changes and only its amplitude does?

Theorem 23.9.2 — Normal Modes

Let $(\mathbf{M}, \mathbf{K})$ be a mass–spring system with n degrees of freedom (Definition 23.9.2).

(a) For $\omega \in \mathbb{R}$ and $\mathbf{v} \in \mathbb{R}^n$ with $\mathbf{v} \neq \mathbf{0}$, the complex-valued function $\mathbf{x}(t) = e^{i\omega t}\mathbf{v}$ satisfies Eq. 23.9.1 if and only if

$$\mathbf{K}\mathbf{v} = \omega^2\mathbf{M}\mathbf{v}.$$

(b) There are real numbers $0 \le \omega_1 \le \cdots \le \omega_n$ and vectors $\mathbf{v}_1, \dots, \mathbf{v}_n \in \mathbb{R}^n$ with

$$\mathbf{K}\mathbf{v}_j = \omega_j^2\mathbf{M}\mathbf{v}_j \quad \text{and} \quad \mathbf{v}_i^{\top}\mathbf{M}\mathbf{v}_j = \delta_{ij},$$

and $(\mathbf{v}_1, \dots, \mathbf{v}_n)$ is a basis of $\mathbb{R}^n$.

(c) Every motion of the system is

$$\mathbf{x}(t) = \sum_{j=1}^{n} c_j(t)\,\mathbf{v}_j,$$

where

$$c_j(t) = \begin{cases} a_j\cos\omega_j t + b_j\sin\omega_j t, & \omega_j > 0, \\ a_j + b_j t, & \omega_j = 0, \end{cases}$$

for uniquely determined real a_j, b_j; conversely every such function is a motion. The coefficients are $a_j = \mathbf{v}_j^{\top}\mathbf{M}\mathbf{x}(0)$, and $b_j = \mathbf{v}_j^{\top}\mathbf{M}\mathbf{x}'(0)/\omega_j$ when $\omega_j > 0$, $b_j = \mathbf{v}_j^{\top}\mathbf{M}\mathbf{x}'(0)$ when $\omega_j = 0$.

The numbers ω_j do not depend on the construction in (b): by Theorem 12.4.2 (b) the ω_j^2 are exactly the roots of $\det(\mathbf{K} - \lambda\mathbf{M})$, with multiplicity. They are the **natural frequencies**, and the pairs $(\omega_j, \mathbf{v}_j)$ are the **normal modes** of the system.

Idea. Part (a) is one differentiation. Part (b) is Chapter 12 §04 verbatim: $\mathbf{M} \succ 0$ is the hypothesis of Theorem 12.4.1, and the columns of the congruence it produces are $\mathbf{M}$-orthonormal generalized eigenvectors by Theorem 12.4.2; all that has to be added is that the generalized eigenvalues are ≥ 0, which is where $\mathbf{K} \succeq 0$ is spent. Part (c) then costs nothing: expanding $\mathbf{x}$ in the basis $(\mathbf{v}_j)$ turns Eq. 23.9.1 into n *separate* scalar

equations, one per mode, and Lemma 23.9.1 solves each.

Proof.

(a) Differentiating twice, $\mathbf{x}''(t) = -\omega^2 e^{i\omega t}\mathbf{v}$, so

$$\mathbf{M}\mathbf{x}''(t) + \mathbf{K}\mathbf{x}(t) = e^{i\omega t}\big(\mathbf{K}\mathbf{v} - \omega^2\mathbf{M}\mathbf{v}\big).$$

Since $e^{i\omega t} \neq 0$ for every t, the left side vanishes for every t if and only if $\mathbf{K}\mathbf{v} = \omega^2\mathbf{M}\mathbf{v}$.

(b) The matrices $\mathbf{M}$ and $\mathbf{K}$ are real symmetric and $\mathbf{M} \succ 0$, so Theorem 12.4.1 gives a real invertible $\mathbf{S}$ with $\mathbf{S}^\top\mathbf{M}\mathbf{S} = \mathbf{I}_n$ and $\mathbf{S}^\top\mathbf{K}\mathbf{S} = \mathbf{D} = \operatorname{diag}(d_1, \dots, d_n)$, the d_j real. Let $\mathbf{s}_1, \dots, \mathbf{s}_n$ be the columns of $\mathbf{S}$. By Theorem 12.4.2 (a), $\mathbf{K}\mathbf{s}_j = d_j\mathbf{M}\mathbf{s}_j$ and $\mathbf{s}_i^\top\mathbf{M}\mathbf{s}_j = \delta_{ij}$. Each d_j is non-negative: the (j,j) entry of $\mathbf{S}^\top\mathbf{K}\mathbf{S}$ is $d_j = \mathbf{s}_j^\top\mathbf{K}\mathbf{s}_j \geq 0$, because $\mathbf{K} \succeq 0$. Put $\omega_j = \sqrt{d_j} \geq 0$, and relabel the columns so that $\omega_1 \leq \cdots \leq \omega_n$; relabeling preserves both displayed properties. The list $(\mathbf{v}_1, \dots, \mathbf{v}_n)$ obtained is the list of columns of an invertible matrix, hence a basis of $\mathbb{R}^n$.

(c) *Every such function is a motion.* Let c_j be as displayed. By Lemma 23.9.1, $c_j'' = -\omega_j^2 c_j$. Hence, differentiating the sum termwise,

$$\mathbf{M}\mathbf{x}'' = \sum_j c_j''\,\mathbf{M}\mathbf{v}_j = -\sum_j \omega_j^2 c_j\,\mathbf{M}\mathbf{v}_j = -\sum_j c_j\,\mathbf{K}\mathbf{v}_j = -\mathbf{K}\mathbf{x},$$

where the third equality is (b).

Every motion is such a function. Let $\mathbf{x}$ be a motion. Since $(\mathbf{v}_j)$ is a basis, write $\mathbf{x}(t) = \sum_j u_j(t)\mathbf{v}_j$. Pairing with $\mathbf{M}\mathbf{v}_j$ and using (b) gives $u_j(t) = \mathbf{v}_j^\top\mathbf{M}\mathbf{x}(t)$, a fixed linear combination of the entries of $\mathbf{x}$, so each u_j is twice differentiable. Substituting into Eq. 23.9.1 and using (b),

$$\sum_j \big(u_j'' + \omega_j^2 u_j\big)\mathbf{M}\mathbf{v}_j = \mathbf{0}.$$

The vectors $\mathbf{M}\mathbf{v}_1, \dots, \mathbf{M}\mathbf{v}_n$ are independent, since $\mathbf{M}$ is invertible and the $\mathbf{v}_j$ are independent, so every coefficient vanishes: $u_j'' = -\omega_j^2 u_j$ for each j. By Lemma 23.9.1 each u_j has the displayed shape, with $a_j = u_j(0)$ and $b_j = u_j'(0)/\omega_j$ or $u_j'(0)$.

The coefficients. Pairing $\mathbf{x}(0) = \sum_i a_i\mathbf{v}_i$ with $\mathbf{M}\mathbf{v}_j$ and using $\mathbf{v}_j^\top\mathbf{M}\mathbf{v}_i = \delta_{ij}$ gives $\mathbf{v}_j^\top\mathbf{M}\mathbf{x}(0) = a_j$; the same computation on $\mathbf{x}'(0) = \sum_i u_i'(0)\mathbf{v}_i$ gives $\mathbf{v}_j^\top\mathbf{M}\mathbf{x}'(0) = u_j'(0)$. Uniqueness of a_j, b_j follows, since they are determined by $\mathbf{x}(0)$ and $\mathbf{x}'(0)$. This proves the theorem.

■

So the general motion has $2n$ real parameters, and the modes evolve independently. Mode j is a motion in which every mass oscillates at the single frequency ω_j, with relative displacements fixed by $\mathbf{v}_j$; the sign pattern of $\mathbf{v}_j$ says which masses move together and which move against each other.

Quick check. Why is the normalization $\mathbf{v}_i^\top\mathbf{M}\mathbf{v}_j = \delta_{ij}$, and not $\mathbf{v}_i^\top\mathbf{v}_j = \delta_{ij}$? Which step of the proof would fail?

Solution. The step reading off the coefficients. What is available is $\mathbf{S}^{\top}\mathbf{M}\mathbf{S} = \mathbf{I}$, which says the $\mathbf{v}_j$ are orthonormal for the inner product $\langle \mathbf{x}, \mathbf{y} \rangle_{\mathbf{M}} = \mathbf{y}^{\top}\mathbf{M}\mathbf{x}$ of Theorem 12.4.2 (a), not for the standard one. Generalized eigenvectors for *different* ω_j need not be orthogonal in the standard sense, and a genuine mass–spring system already shows it: for $\mathbf{M} = \operatorname{diag}(2,1)$ and $\mathbf{K} = \left(\begin{smallmatrix} 3 & -1 \\ -1 & 1 \end{smallmatrix}\right)$ the modes are the multiples of $(1,2)$, for $\omega^2 = \frac{1}{2}$, and of $(1,-1)$, for $\omega^2 = 2$; and $(1,2)^{\top}\mathbf{M}(1,-1) = 0$ while $(1,2)\cdot(1,-1) = -1 \neq 0$. So here the two normalizations cannot both be imposed: rescaling the $\mathbf{v}_j$ to standard unit length keeps them generalized eigenvectors but destroys $\mathbf{v}_i^{\top}\mathbf{M}\mathbf{v}_j = \delta_{ij}$, and the pairing step then has no δ_{ij} to use. (When $\mathbf{M} = c\mathbf{I}$ the two conditions differ by a constant only, and both can be met at once.)

Example. (Three equal masses, four equal springs)

Take $n = 3$ with every mass m and every stiffness k, so that $\mathbf{M} = m\mathbf{I}_3$ and $\mathbf{K} = k\mathbf{K}_3$ as in Example (Three systems) (b). Find the natural frequencies and the normal modes of Theorem 23.9.2.

Solution. The pencil. Here $\mathbf{K}\mathbf{v} = \omega^2\mathbf{M}\mathbf{v}$ reads $k\mathbf{K}_3\mathbf{v} = m\omega^2\mathbf{v}$, an ordinary eigenvalue problem for the symmetric matrix

$$\mathbf{K}_3 = \begin{pmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{pmatrix},$$

with $\omega^2 = (k/m)\mu$ for μ an eigenvalue of $\mathbf{K}_3$.

Eigenvalues. Expanding along the first row, $\det(\mathbf{K}_3 - \mu\mathbf{I}) = (2-\mu)^3 - 2(2-\mu) = (2-\mu)\big((2-\mu)^2 - 2\big)$, so

$$\mu = 2 - \sqrt{2}, \qquad \mu = 2, \qquad \mu = 2 + \sqrt{2}.$$

Eigenvectors. For $\mu = 2$ the first row of $\mathbf{K}_3 - 2\mathbf{I}$ gives $-v_2 = 0$ and the second gives $-v_1 - v_3 = 0$, so $\mathbf{v} \propto (1,0,-1)$. For $\mu = 2 \mp \sqrt{2}$, so that $2 - \mu = \pm\sqrt{2}$, the first row reads $(2-\mu)v_1 - v_2 = 0$ and the third reads $-v_2 + (2-\mu)v_3 = 0$, giving $v_2 = \pm\sqrt{2}\,v_1$ and $v_2 = \pm\sqrt{2}\,v_3$, so $\mathbf{v} \propto (1, \pm\sqrt{2}, 1)$. The middle row is then automatic: it reads $-1 + (2-\mu)(\pm\sqrt{2}) - 1 = -2 + 2 = 0$. Direct substitution confirms all three.

Normalizing. Since $\mathbf{M} = m\mathbf{I}_3$, the condition $\mathbf{v}^{\top}\mathbf{M}\mathbf{v} = 1$ is $m\|\mathbf{v}\|^2 = 1$. The squared lengths are $4, 2, 4$, so

$$\mathbf{v}_1 = \tfrac{1}{2\sqrt{m}}\begin{pmatrix} 1 \\ \sqrt{2} \\ 1 \end{pmatrix}, \quad \mathbf{v}_2 = \tfrac{1}{\sqrt{2m}}\begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}, \quad \mathbf{v}_3 = \tfrac{1}{2\sqrt{m}}\begin{pmatrix} 1 \\ -\sqrt{2} \\ 1 \end{pmatrix},$$

and the natural frequencies are

$$\omega_1 = \sqrt{\tfrac{k}{m}}\sqrt{2 - \sqrt{2}}, \quad \omega_2 = \sqrt{\tfrac{k}{m}}\sqrt{2}, \quad \omega_3 = \sqrt{\tfrac{k}{m}}\sqrt{2 + \sqrt{2}},$$

approximately $0.765, 1.414$ and 1.848 times $\sqrt{k/m}$.

Reading the modes. In mode 1 all three masses move the same way, the middle one furthest: the slowest and softest motion. In mode 2 the middle mass stands still and the

outer two move oppositely. In mode 3 neighbors always move oppositely, which stretches every spring at once and costs the most: the fastest motion. The number of sign changes along the chain increases with the frequency. That is a general phenomenon for such chains, an oscillation theorem for tridiagonal stiffness matrices; nothing in this section uses it, and this book does not prove it.

23.9.3 Frequencies as a minimum

Theorem 23.9.2 computes the frequencies exactly, at the price of solving an n-th degree equation. Often one wants instead a cheap estimate of the lowest frequency, and a way to say how it responds to a change in the design. Both come from a quotient.

Definition 23.9.3 — Generalized Rayleigh quotient

Let $(\mathbf{M}, \mathbf{K})$ be a mass–spring system. Its **generalized Rayleigh quotient** is

$$\rho(\mathbf{v}) := \frac{\mathbf{v}^\top \mathbf{K}\mathbf{v}}{\mathbf{v}^\top \mathbf{M}\mathbf{v}},$$

defined for every $\mathbf{v} \in \mathbb{R}^n$ with $\mathbf{v} \neq \mathbf{0}$, and at no other vector.

The denominator is non-zero exactly because $\mathbf{M} \succ 0$, which is the role definiteness played in Definition 16.1.1; for $\mathbf{M} = \mathbf{I}$ the two definitions agree. Physically $\rho(\mathbf{v})$ is the potential energy of the deformation $\mathbf{v}$ divided by the kinetic energy of the velocity $\mathbf{v}$: the stiffness-to-inertia ratio of the shape $\mathbf{v}$. It is unchanged by scaling, since both numerator and denominator pick up c^2.

Corollary 23.9.3 — Frequencies from the Rayleigh Quotient

Let $(\mathbf{M}, \mathbf{K})$ be a mass–spring system with natural frequencies $\omega_1 \leq \cdots \leq \omega_n$. Then for every j,

$$\begin{aligned} \omega_j^2 &= \min_{\dim W = j} \ \max_{\mathbf{0} \neq \mathbf{v} \in W} \ \rho(\mathbf{v}) \\ &= \max_{\dim W = n-j+1} \ \min_{\mathbf{0} \neq \mathbf{v} \in W} \ \rho(\mathbf{v}), \end{aligned}$$

W running over all subspaces of $\mathbb{R}^n$ of the stated dimension. In particular

$$\omega_1^2 = \min_{\mathbf{v} \neq \mathbf{0}} \rho(\mathbf{v}), \qquad \omega_n^2 = \max_{\mathbf{v} \neq \mathbf{0}} \rho(\mathbf{v}),$$

and every $\mathbf{v} \neq \mathbf{0}$ gives the upper bound $\omega_1^2 \leq \rho(\mathbf{v})$, with equality exactly when $\mathbf{v}$ is a generalized eigenvector for ω_1.

Idea. The congruence $\mathbf{S}$ of Theorem 23.9.2 turns ρ into the ordinary Rayleigh quotient of the diagonal matrix $\mathbf{D}$: substituting $\mathbf{v} = \mathbf{S}\mathbf{y}$ replaces the numerator by $\mathbf{y}^\top \mathbf{D}\mathbf{y}$ and the denominator by $\mathbf{y}^\top \mathbf{y}$. Since $\mathbf{S}$ is invertible it matches subspaces of dimension j with subspaces of dimension j, so an optimization over subspaces is carried across unchanged, and Theorem 16.2.3 applies. The only care needed is the index: Chapter 16 orders eigenvalues **decreasingly** and frequencies are ordered **increasingly**, so $\omega_j^2 = \lambda_{n-j+1}(\mathbf{D})$.

Proof. Let $\mathbf{S}$ and $\mathbf{D} = \operatorname{diag}(d_1, \dots, d_n)$ be as in the proof of Theorem 23.9.2, so $\mathbf{S}^\top \mathbf{M}\mathbf{S} = \mathbf{I}_n$, $\mathbf{S}^\top \mathbf{K}\mathbf{S} = \mathbf{D}$, and the multiset $\{d_1, \dots, d_n\}$ is $\{\omega_1^2, \dots, \omega_n^2\}$. For $\mathbf{y} \neq \mathbf{0}$ put $\mathbf{v} = \mathbf{S}\mathbf{y}$, which is non-zero because $\mathbf{S}$ is invertible. Then

$$\rho(\mathbf{S}\mathbf{y}) = \frac{\mathbf{y}^\top \mathbf{S}^\top \mathbf{K}\mathbf{S}\mathbf{y}}{\mathbf{y}^\top \mathbf{S}^\top \mathbf{M}\mathbf{S}\mathbf{y}} = \frac{\mathbf{y}^\top \mathbf{D}\mathbf{y}}{\mathbf{y}^\top \mathbf{y}} = R_{\mathbf{D}}(\mathbf{y}),$$

the last step by Definition 16.1.1, $\mathbf{D}$ being real diagonal and hence Hermitian.

Fix j and put $k = n - j + 1$. Sorting $d_1, \dots, d_n$ decreasingly as in Chapter 16 makes $\lambda_k(\mathbf{D})$ the j-th smallest of them, that is $\lambda_k(\mathbf{D}) = \omega_j^2$. By Theorem 16.2.3,

$$\omega_j^2 = \lambda_k(\mathbf{D}) = \min_{\dim W' = n-k+1} \; \max_{\mathbf{0} \neq \mathbf{y} \in W'} R_{\mathbf{D}}(\mathbf{y}),$$

and $n - k + 1 = j$. The map $W' \mapsto \mathbf{S}W'$ is a bijection from the j-dimensional subspaces of $\mathbb{R}^n$ to themselves, since $\mathbf{S}$ is invertible, and it carries the non-zero vectors of W' onto those of $\mathbf{S}W'$; combined with the displayed identity $\rho(\mathbf{S}\mathbf{y}) = R_{\mathbf{D}}(\mathbf{y})$, the inner maximum over W' for $R_{\mathbf{D}}$ equals the inner maximum over $\mathbf{S}W'$ for ρ. Hence the two outer minima agree, which is the first line. The second line is the second equality of Theorem 16.2.3 transported in the same way, with $n - k + 1$ replaced by $k = n - j + 1$.

For the particular cases, take $j = 1$ and $j = n$ in the second and the first line respectively, where the only admissible W is $\mathbb{R}^n$ itself. Equality in $\omega_1^2 \leq \rho(\mathbf{v})$ holds exactly when $\mathbf{y} = \mathbf{S}^{-1}\mathbf{v}$ attains the minimum of $R_{\mathbf{D}}$, and that happens exactly at the eigenvectors of $\mathbf{D}$ for its smallest eigenvalue. In one direction, such an eigenvector attains the minimum by Proposition 16.1.1. Conversely, suppose $\mathbf{y} \neq \mathbf{0}$ attains it; replacing $\mathbf{y}$ by $\mathbf{y}/\|\mathbf{y}\|$ changes nothing, since $R_{\mathbf{D}}(c\mathbf{y}) = R_{\mathbf{D}}(\mathbf{y})$ for $c \neq 0$ directly from Definition 16.1.1, so we may take $\mathbf{y}$ to be a unit vector. Then Proposition 16.1.2 (b) applies in its minimum form and gives the condition of its part (a), whence $\mathbf{D}\mathbf{y} = R_{\mathbf{D}}(\mathbf{y})\mathbf{y}$ by that part, and $R_{\mathbf{D}}(\mathbf{y}) = \lambda_n(\mathbf{D})$ is the smallest eigenvalue by Proposition 16.1.1. Multiplying by $\mathbf{S}$ turns these into the generalized eigenvectors for ω_1, by Theorem 12.4.2 (a). This proves the corollary.

■

The practical content is the last sentence: **any** shape you can guess gives an upper bound for the lowest squared frequency, and the bound is good even when the guess is mediocre, because the quotient is flat at a minimum.

Example. (Guessing the lowest mode of the chain)

For the chain of Example (Three equal masses, four equal springs) with $k = m = 1$, estimate ω_1^2 by guessing a shape, without computing any eigenvalue.

Solution. The lowest mode should have all three masses moving together, so try $\mathbf{g} = (1, 1, 1)$. Then $\mathbf{K}_3\mathbf{g} = (1, 0, 1)$, so

$$\rho(\mathbf{g}) = \frac{\mathbf{g}^\top \mathbf{K}_3 \mathbf{g}}{\mathbf{g}^\top \mathbf{g}} = \frac{2}{3} \approx 0.6667.$$

The true value is $2 - \sqrt{2} \approx 0.5858$, so the guess overestimates by about 14% — and, by Corollary 23.9.3, it is certainly an overestimate.

Refine it: the middle mass should swing furthest, so try $\mathbf{g} = (2, 3, 2)$. Now $\mathbf{K}_3\mathbf{g} = (1, 2, 1)$, and

$$\rho(\mathbf{g}) = \frac{2+6+2}{4+9+4} = \frac{10}{17} \approx 0.5882.$$

The error has fallen to about 0.4%. The exact mode is $(1, \sqrt{2}, 1) \propto (2, 2\sqrt{2}, 2)$ and $2\sqrt{2} \approx 2.83$, so the guess $(2, 3, 2)$ is still off by about 6% in its middle entry: the *shape* is wrong by 6% and the *frequency* by 0.4%. Squaring the error in the shape is exactly what Proposition 16.1.2 predicts near a critical point of the quotient.

Quick check. The guess $\mathbf{g} = (1, 2, 1)$ also gives $\rho(\mathbf{g}) = 2/3$, the same as $(1, 1, 1)$, although $(1, 2, 1)$ is much closer to the true mode $(1, \sqrt{2}, 1)$. Is that a contradiction?

Solution. No. $\mathbf{K}_3(1, 2, 1) = (0, 2, 0)$, so $\rho = 4/6 = 2/3$. Both guesses lie on the same level set of ρ, and a level set is not a sphere around the minimizer: the quotient measures a ratio of energies, not a distance to $\mathbf{v}_1$. Being closer to the true mode in the Euclidean sense does not force a smaller value, only being closer *in the right directions* does. What Corollary 23.9.3 guarantees is one-sided, that both values are $\geq 2 - \sqrt{2}$, and both are.

23.9.4 Stiffer, heavier, pinned

The min–max description compares two systems, because the family of subspaces it runs over does not depend on the matrices. Three design changes can now be read off.

Proposition 23.9.4 — Stiffening Raises, Loading Lowers

Let $(\mathbf{M}, \mathbf{K})$ and $(\mathbf{M}', \mathbf{K}')$ be mass–spring systems with n degrees of freedom, with natural frequencies ω_j and ω'_j.

(a) If $\mathbf{M}' = \mathbf{M}$ and $\mathbf{K}' \succeq \mathbf{K}$, then $\omega'_j \geq \omega_j$ for every j.
(b) If $\mathbf{K}' = \mathbf{K}$ and $\mathbf{M}' \succeq \mathbf{M}$, then $\omega'_j \leq \omega_j$ for every j.

Idea. Both are the same one-line observation: the hypothesis makes ρ' compare with ρ at **every** vector, and a min–max of a larger function is larger. In (b) the numerator must be non-negative before enlarging the denominator helps, and that is exactly the hypothesis $\mathbf{K} \succeq 0$ from Definition 23.9.2.

Proof.

(a) Let $\mathbf{v} \neq \mathbf{0}$. By Definition 12.5.1, $\mathbf{v}^\top\mathbf{K}'\mathbf{v} \geq \mathbf{v}^\top\mathbf{K}\mathbf{v}$, and the two quotients have the same positive denominator $\mathbf{v}^\top\mathbf{M}\mathbf{v}$, so $\rho'(\mathbf{v}) \geq \rho(\mathbf{v})$. Fix j and a subspace W of dimension j. Then $\max_{\mathbf{0}\neq\mathbf{v}\in W} \rho'(\mathbf{v}) \geq \max_{\mathbf{0}\neq\mathbf{v}\in W} \rho(\mathbf{v})$, since the maximum of the larger function over the same set is larger; taking the minimum over all such W preserves the inequality. By Corollary 23.9.3 applied to each system, the two sides are $(\omega'_j)^2$ and ω_j^2. Both frequencies are ≥ 0, so $\omega'_j \geq \omega_j$.

(b) Let $\mathbf{v} \neq \mathbf{0}$. Now $\mathbf{v}^\top\mathbf{M}'\mathbf{v} \geq \mathbf{v}^\top\mathbf{M}\mathbf{v} > 0$ by Definition 12.5.1 and $\mathbf{M} \succ 0$, while the common numerator satisfies $\mathbf{v}^\top\mathbf{K}\mathbf{v} \geq 0$ because $\mathbf{K} \succeq 0$. Increasing a positive denominator does not increase a non-negative fraction, so $\rho'(\mathbf{v}) \leq \rho(\mathbf{v})$, and the

argument of (a) runs in reverse. This proves the proposition.

■

Part (b) needs $\mathbf{K} \succeq 0$ and not merely $\mathbf{K} = \mathbf{K}^\top$: for a 1×1 system with $\mathbf{K} = (-1)$, replacing $\mathbf{M} = (1)$ by $\mathbf{M}' = (4)$ moves the quotient from -1 up to $-1/4$. Such a $\mathbf{K}$ is not a stiffness matrix, and the definition excludes it for this reason among others.

The third change is to hold one mass still — to **pin** it. Constraining $x_p = 0$ leaves a system with $n - 1$ degrees of freedom whose matrices are obtained by deleting row and column p.

Proposition 23.9.5 — Pinning Interlaces the Frequencies

Let $(\mathbf{M}, \mathbf{K})$ be a mass–spring system with $n \geq 2$ degrees of freedom and natural frequencies $\omega_1 \leq \cdots \leq \omega_n$. Fix p, let $I = \{1, \ldots, n\} \setminus \{p\}$, and let $\mathbf{M}' = \mathbf{M}_{I,I}$ and $\mathbf{K}' = \mathbf{K}_{I,I}$ be the principal submatrices on I. Then $(\mathbf{M}', \mathbf{K}')$ is a mass–spring system with $n - 1$ degrees of freedom, and its natural frequencies $\mu_1 \leq \cdots \leq \mu_{n-1}$ satisfy

$$\omega_j \;\leq\; \mu_j \;\leq\; \omega_{j+1} \qquad (1 \leq j \leq n - 1).$$

Idea. Pinning restricts the competition to the hyperplane $H = \{\mathbf{v} : v_p = 0\}$. A subspace of H is a subspace of $\mathbb{R}^n$, so the min–max for the pinned system runs over *fewer* competitors than the one for the full system; that gives the left inequality at index j and, after the dimension count that makes Theorem 16.4.2 work, the right one at index $j + 1$.

Proof. Let $H = \{\mathbf{v} \in \mathbb{R}^n : v_p = 0\}$ and let $\varphi \colon H \to \mathbb{R}^{n-1}$ delete the p-th coordinate, a linear isomorphism. For $\mathbf{v} \in H$ with coordinates $\mathbf{y} = \varphi(\mathbf{v})$, the terms of $\mathbf{v}^\top \mathbf{M} \mathbf{v}$ involving index p all vanish, so

$$\mathbf{v}^\top \mathbf{M} \mathbf{v} = \mathbf{y}^\top \mathbf{M}' \mathbf{y}, \qquad \mathbf{v}^\top \mathbf{K} \mathbf{v} = \mathbf{y}^\top \mathbf{K}' \mathbf{y},$$

Both $\mathbf{M}'$ and $\mathbf{K}'$ are symmetric, being principal submatrices of symmetric matrices, and the displays give $\mathbf{y}^\top \mathbf{M}' \mathbf{y} > 0$ for $\mathbf{y} \neq \mathbf{0}$ and $\mathbf{y}^\top \mathbf{K}' \mathbf{y} \geq 0$ for all $\mathbf{y}$, since φ is onto and $\varphi^{-1}(\mathbf{y}) \neq \mathbf{0}$ for $\mathbf{y} \neq \mathbf{0}$; so $\mathbf{M}' \succ 0$ and $\mathbf{K}' \succeq 0$ by Definition 12.1.1, and $(\mathbf{M}', \mathbf{K}')$ is a mass–spring system. Writing ρ and ρ' for the two generalized Rayleigh quotients, the two displays give

$$\rho(\mathbf{v}) = \rho'(\varphi(\mathbf{v})) \qquad \text{for } \mathbf{0} \neq \mathbf{v} \in H.$$

Fix j with $1 \leq j \leq n - 1$.

$(\omega_j \leq \mu_j)$ By Corollary 23.9.3 for the pinned system there is a subspace $W' \leq \mathbb{R}^{n-1}$ with $\dim W' = j$ and $\mu_j^2 = \max_{\mathbf{0} \neq \mathbf{y} \in W'} \rho'(\mathbf{y})$. Put $W = \varphi^{-1}(W') \leq H \leq \mathbb{R}^n$, of dimension j. Then $\max_{\mathbf{0} \neq \mathbf{v} \in W} \rho(\mathbf{v}) = \mu_j^2$, and W is one of the competitors in the min–max for ω_j^2, so $\omega_j^2 \leq \mu_j^2$.

$(\mu_j \leq \omega_{j+1})$ By the max–min line of Corollary 23.9.3 for the pinned system there is a subspace $W' \leq \mathbb{R}^{n-1}$ with $\dim W' = (n-1) - j + 1 = n - j$ and $\mu_j^2 = \min_{\mathbf{0} \neq \mathbf{y} \in W'} \rho'(\mathbf{y})$. Put $W = \varphi^{-1}(W') \leq \mathbb{R}^n$, of dimension $n - j = n - (j+1) + 1$, which is the dimension

the max–min line for ω_{j+1}^2 asks for. Hence

$$\omega_{j+1}^2 \;\geq\; \min_{\mathbf{0}\neq\mathbf{v}\in W} \rho(\mathbf{v}) = \mu_j^2.$$

All frequencies being ≥ 0, taking square roots preserves both inequalities. This proves the proposition.

■

Example. (Pinning the middle mass)

In Example (Three equal masses, four equal springs) with $k = m = 1$, hold mass 2 fixed. Deleting row and column 2 from $\mathbf{K}_3$ and from $\mathbf{I}_3$ gives $\mathbf{K}' = \operatorname{diag}(2, 2)$ and $\mathbf{M}' = \mathbf{I}_2$, so the pinned frequencies are $\mu_1 = \mu_2 = \sqrt{2}$. The unpinned ones are $\sqrt{2 - \sqrt{2}} \approx 0.765$, $\sqrt{2} \approx 1.414$ and $\sqrt{2 + \sqrt{2}} \approx 1.848$, and indeed

$$0.765 \leq 1.414 \leq 1.414 \leq 1.414 \leq 1.848,$$

which is Proposition 23.9.5, here with two of the four inequalities equalities. The answer is also visible: with the middle mass pinned, the two outer masses no longer interact, and each is a single mass between two unit springs, of frequency $\sqrt{2}$.

Three sentences summarize the section. A structure's frequencies are the generalized eigenvalues of a definite pencil, and its modes are an $\mathbf{M}$-orthonormal basis, so its motion decouples completely. Each frequency is a min–max of one explicit quotient, so a guessed shape bounds the lowest one from above. And because the min–max runs over a family of subspaces that does not mention the matrices, making a structure stiffer raises every frequency, making it heavier lowers every frequency, and pinning a point interlaces them.

23.9.5 Exercises

23.9.5.1 A. Check your understanding

Exercise A1.

(a) State the two hypotheses on $\mathbf{M}$ and $\mathbf{K}$ in Definition 23.9.2, and say which one guarantees that $\rho(\mathbf{v})$ is defined for every $\mathbf{v} \neq \mathbf{0}$.

(b) State Theorem 23.9.2 (b), including the normalization of the eigenvectors.

(c) A system has $\mathbf{K}$ invertible. What does Theorem 23.9.2 say about ω_1? What if $\mathbf{K}$ is singular?

(d) True or false: if every stiffness k_e of a chain is doubled and every mass is left alone, every natural frequency is multiplied by $\sqrt{2}$. Justify your answer.

(e) True or false: for $\mathbf{M} = \operatorname{diag}(1, 4)$ the squared natural frequencies are the eigenvalues of $\mathbf{K}$ divided by 1 and by 4 in some order. Justify your answer.

Solution.

(a) $\mathbf{M} \succ 0$ and $\mathbf{K} \succeq 0$, both symmetric. It is $\mathbf{M} \succ 0$ that makes the denominator

$\mathbf{v}^{\top}\mathbf{M}\mathbf{v}$ non-zero, hence positive, for every $\mathbf{v} \neq \mathbf{0}$.

(b) There are $0 \leq \omega_1 \leq \cdots \leq \omega_n$ and a basis $\mathbf{v}_1, \ldots, \mathbf{v}_n$ of $\mathbb{R}^n$ with $\mathbf{K}\mathbf{v}_j = \omega_j^2 \mathbf{M}\mathbf{v}_j$ and $\mathbf{v}_i^{\top}\mathbf{M}\mathbf{v}_j = \delta_{ij}$: the eigenvectors are orthonormal for the $\mathbf{M}$-inner product, not for the standard one.

(c) If $\mathbf{K}$ is invertible then no ω_j is 0: $\omega_j = 0$ would give $\mathbf{K}\mathbf{v}_j = \mathbf{0}$ with $\mathbf{v}_j \neq \mathbf{0}$. So $\omega_1 > 0$ and every motion is a genuine oscillation. If $\mathbf{K}$ is singular then some $\omega_j = 0$, and by Theorem 23.9.2 (c) there are motions containing a term $b_j t\,\mathbf{v}_j$, which grow without bound: a drift, not a vibration.

(d) True. Replacing $\mathbf{K}$ by $2\mathbf{K}$ multiplies ρ by 2 at every vector, hence multiplies every min–max by 2 (Corollary 23.9.3), hence every ω_j^2 by 2 and every ω_j by $\sqrt{2}$.

(e) False; the warning above gives $\mathbf{K} = \left(\begin{smallmatrix} 2 & -1 \\ -1 & 2 \end{smallmatrix}\right)$ with $\mathbf{M} = \operatorname{diag}(1, 4)$, whose squared frequencies are $(5 \pm \sqrt{13})/4$, irrational, while the four candidate quotients $3, 3/4, 1, 1/4$ are rational.

23.9.5.2 B. Practice

Exercise B1: Two masses, two springs.

A cart of mass 2 is joined to a wall by a spring of stiffness 2, and a cart of mass 1 is joined to the first cart by a spring of stiffness 1; the second cart is free on the right.

(a) Write down $\mathbf{M}$ and $\mathbf{K}$.

(b) Find the natural frequencies and an $\mathbf{M}$-orthonormal basis of normal modes.

(c) Verify directly that the two modes are $\mathbf{M}$-orthogonal but **not** orthogonal for the standard inner product.

Solution.

(a) With x_1, x_2 the displacements, Newton and Hooke give $2x_1'' = -2x_1 + (x_2 - x_1)$ and $x_2'' = -(x_2 - x_1)$, so

$$\mathbf{M} = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}, \qquad \mathbf{K} = \begin{pmatrix} 3 & -1 \\ -1 & 1 \end{pmatrix}.$$

Both are symmetric, $\mathbf{M} \succ 0$, and $\mathbf{K} \succ 0$ since its leading minors are 3 and 2 (Theorem 12.1.5).

(b) Expanding the determinant of the pencil,

$$\begin{aligned} \det(\mathbf{K} - \lambda\mathbf{M}) &= (3 - 2\lambda)(1 - \lambda) - 1 \\ &= 2\lambda^2 - 5\lambda + 2 = (2\lambda - 1)(\lambda - 2), \end{aligned}$$

so $\omega_1^2 = \tfrac{1}{2}$ and $\omega_2^2 = 2$, that is $\omega_1 = 1/\sqrt{2}$ and $\omega_2 = \sqrt{2}$. For $\lambda = \tfrac{1}{2}$, $\mathbf{K} - \tfrac{1}{2}\mathbf{M} = \left(\begin{smallmatrix} 2 & -1 \\ -1 & 1/2 \end{smallmatrix}\right)$ has kernel spanned by $(1, 2)$; for $\lambda = 2$, $\mathbf{K} - 2\mathbf{M} = \left(\begin{smallmatrix} -1 & -1 \\ -1 & -1 \end{smallmatrix}\right)$ has kernel spanned by $(1, -1)$. Since $(1,2)^{\top}\mathbf{M}(1,2) = 2 + 4 = 6$ and $(1,-1)^{\top}\mathbf{M}(1,-1) = 2 + 1 = 3$,

$$\mathbf{v}_1 = \tfrac{1}{\sqrt{6}}(1, 2), \qquad \mathbf{v}_2 = \tfrac{1}{\sqrt{3}}(1, -1).$$

In the slow mode the two carts move together, the light one further; in the fast mode they move against each other.

(c) $(1,2)^\top \mathbf{M}(1,-1) = 2\cdot 1\cdot 1 + 1\cdot 2\cdot(-1) = 0$, so they are $\mathbf{M}$-orthogonal, as Theorem 23.9.2 (b) requires. But $(1,2)\cdot(1,-1) = 1-2 = -1 \neq 0$: the standard inner product does not see the modes.

Exercise B2: Bounding the slowest mode.

For the system of Exercise B1, estimate ω_1^2 from above using the guesses $\mathbf{g} = (1,1)$ and $\mathbf{g} = (2,3)$, and compare with the exact value.

Solution. For $\mathbf{g} = (1,1)$: $\mathbf{g}^\top\mathbf{K}\mathbf{g} = 3-1-1+1 = 2$ and $\mathbf{g}^\top\mathbf{M}\mathbf{g} = 2+1 = 3$, so $\rho(\mathbf{g}) = 2/3 \approx 0.667$.

For $\mathbf{g} = (2,3)$: $\mathbf{K}\mathbf{g} = (6-3, -2+3) = (3,1)$, so $\mathbf{g}^\top\mathbf{K}\mathbf{g} = 6+3 = 9$; and $\mathbf{g}^\top\mathbf{M}\mathbf{g} = 8+9 = 17$, so $\rho(\mathbf{g}) = 9/17 \approx 0.529$.

The exact value is $\omega_1^2 = 1/2$. Both estimates exceed it, as Corollary 23.9.3 requires, and the second guess, being nearer the true mode $(1,2) \propto (2,4)$, is much nearer the true value.

Exercise B3: Stiffening a chain.

In the system of Exercise B1, the stiffness of the second spring is increased from 1 to 2, so that $\mathbf{K}$ becomes $\mathbf{K}' = \left(\begin{smallmatrix} 4 & -2 \\ -2 & 2 \end{smallmatrix}\right)$.

(a) Verify that $\mathbf{K}' \succeq \mathbf{K}$.

(b) Compute the new squared frequencies and check Proposition 23.9.4 (a).

Solution.

(a) $\mathbf{K}' - \mathbf{K} = \left(\begin{smallmatrix} 1 & -1 \\ -1 & 1 \end{smallmatrix}\right)$, whose trace is 2 and determinant 0, so its eigenvalues are 2 and 0 and it is positive semidefinite (Theorem 12.1.4). Hence $\mathbf{K}' \succeq \mathbf{K}$ by Definition 12.5.1. Directly: $\mathbf{v}^\top(\mathbf{K}' - \mathbf{K})\mathbf{v} = (v_1 - v_2)^2 \geq 0$, which is the extra spring energy.

(b) $\det(\mathbf{K}' - \lambda\mathbf{M}) = (4-2\lambda)(2-\lambda) - 4 = 2\lambda^2 - 8\lambda + 4$, so the squared frequencies are $2 \pm \sqrt{2}$, about 0.586 and 3.414. The old ones were 0.5 and 2, and $0.586 \geq 0.5$, $3.414 \geq 2$, as Proposition 23.9.4 (a) requires. Note the two increases are quite different in size: the proposition orders the frequencies, it does not move them by a common amount.

23.9.5.3 C. Going deeper

Exercise C1: The free chain drifts.

Let $(\mathbf{M}, \mathbf{K})$ be a mass–spring system.

(a) Prove that $\omega_1 = 0$ if and only if $\mathbf{K}$ is singular, and that in that case the generalized eigenvectors for $\omega = 0$ are exactly the non-zero vectors of $\ker \mathbf{K}$.

(b) Hence describe all motions of the free chain of Example (Three systems) (c) with three equal masses m and equal inner stiffnesses k, given that $\ker \mathbf{K}$ is spanned by $\mathbf{1}$.

(c) Deduce that the total momentum $\sum_i m_i x_i'(t)$ of the free chain is constant in time.

Solution.

(a) By Theorem 23.9.2 (b), $\omega_1 = 0$ if and only if some $\mathbf{v} \neq \mathbf{0}$ has $\mathbf{K}\mathbf{v} = 0 \cdot \mathbf{M}\mathbf{v} = \mathbf{0}$, that is if and only if $\ker \mathbf{K} \neq \{\mathbf{0}\}$, that is if and only if $\mathbf{K}$ is singular (Theorem 2.4.4). For such an ω the equation $\mathbf{K}\mathbf{v} = \omega^2 \mathbf{M}\mathbf{v}$ reads $\mathbf{K}\mathbf{v} = \mathbf{0}$, so its non-zero solutions are exactly the non-zero vectors of $\ker \mathbf{K}$.

(b) Here $\mathbf{M} = m\mathbf{I}_3$ and $\mathbf{K} = k\begin{pmatrix} 1 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 1 \end{pmatrix}$, whose kernel is $\operatorname{span}(\mathbf{1})$, one-dimensional. So $\omega_1 = 0$ with mode $\mathbf{v}_1 = \mathbf{1}/\sqrt{3m}$, and the other two frequencies are positive. By Theorem 23.9.2 (c) every motion is

$$\mathbf{x}(t) = (a_1 + b_1 t)\mathbf{v}_1 + \sum_{j=2}^{3} \bigl(a_j \cos \omega_j t + b_j \sin \omega_j t\bigr)\mathbf{v}_j \,:$$

an oscillation superposed on a uniform drift of the whole chain. The drift is the motion Theorem 23.9.2 produces for a singular $\mathbf{K}$, and physically it is the chain floating away at constant speed.

(c) The total momentum is $\mathbf{1}^{\top}\mathbf{M}\mathbf{x}'(t)$. Differentiating and using Eq. 23.9.1, $\mathbf{1}^{\top}\mathbf{M}\mathbf{x}''(t) = -\mathbf{1}^{\top}\mathbf{K}\mathbf{x}(t) = -(\mathbf{K}\mathbf{1})^{\top}\mathbf{x}(t) = 0$, where $\mathbf{K}^{\top} = \mathbf{K}$ and $\mathbf{K}\mathbf{1} = \mathbf{0}$ were used. A differentiable function with vanishing derivative is constant, so $\mathbf{1}^{\top}\mathbf{M}\mathbf{x}'(t)$ does not depend on t.

Exercise C2: Adding a mass cannot raise a frequency, and can lower it a lot.

(a) Let $(\mathbf{M}, \mathbf{K})$ be a mass–spring system and let $t > 0$. Prove that the system $(\mathbf{M} + t\mathbf{e}_p\mathbf{e}_p^{\top}, \mathbf{K})$, obtained by adding mass t to the p-th degree of freedom, has $\omega_j'(t) \leq \omega_j$ for every j, and that $t \mapsto \omega_j'(t)$ is non-increasing.

(b) For the single mass of Example (Three systems) (a) with $m = k_1 = k_2 = 1$, compute $\omega_1'(t)$ exactly and find $\lim_{t\to\infty} \omega_1'(t)$.

(c) Give an example of a mass–spring system and a p for which adding mass at p leaves the **largest** frequency unchanged. *Hint: look for a mode that does not move the p-th mass.*

Solution.

(a) The matrix $t\mathbf{e}_p\mathbf{e}_p^{\top}$ is symmetric with $\mathbf{v}^{\top}(t\mathbf{e}_p\mathbf{e}_p^{\top})\mathbf{v} = tv_p^2 \geq 0$, so it is positive semidefinite and $\mathbf{M} + t\mathbf{e}_p\mathbf{e}_p^{\top} \succeq \mathbf{M}$. By Proposition 23.9.4 (b), $\omega_j'(t) \leq \omega_j$ for every j. For monotonicity in t, if $0 < s \leq t$ then $\mathbf{M} + t\mathbf{e}_p\mathbf{e}_p^{\top} \succeq \mathbf{M} + s\mathbf{e}_p\mathbf{e}_p^{\top}$, because the difference is $(t-s)\mathbf{e}_p\mathbf{e}_p^{\top} \succeq 0$, and applying (b) again to these two systems gives $\omega_j'(t) \leq \omega_j'(s)$.

(b) Here $n = 1$, $\mathbf{M} = (1 + t)$ and $\mathbf{K} = (2)$, so the single squared frequency is $\rho(1) = 2/(1+t)$ and $\omega_1'(t) = \sqrt{2/(1+t)}$. It is decreasing in t and tends to 0: an infinitely heavy cart does not move.

(c) Let $n = 2$, $\mathbf{M} = \mathbf{I}_2$ and $\mathbf{K} = \operatorname{diag}(1, 4)$, so $\omega_1^2 = 1$, $\omega_2^2 = 4$ with modes $\mathbf{e}_1, \mathbf{e}_2$. Adding mass at $p = 1$ gives $\mathbf{M}' = \operatorname{diag}(1 + t, 1)$, and $\det(\mathbf{K} - \lambda\mathbf{M}') = (1 - \lambda(1 + t))(4 - \lambda)$, whose roots are $1/(1 + t)$ and 4. The largest squared frequency is still

> 4, because its mode $\mathbf{e}_2$ has no component at $p = 1$ and the added mass therefore never moves in that mode. This also shows the inequalities of Proposition 23.9.4 (b) can be equalities.

23.10 Principal Components

Chapter 12 §10 proved that the k-dimensional subspace **through the origin** closest to a cloud of points is spanned by the leading left singular vectors, and then said plainly what it had not proved: the centering, the covariance matrix, and the reading of $\sigma_i^2 / \sum_l \sigma_l^2$ as a fraction of variance. This section supplies all three — and the variance fraction turns out to be a theorem, not a convention — and then marks exactly where linear algebra stops and statistics begins. The honest answer is: more is provable than one might expect, and less than the phrase "explained variance" usually suggests.

Throughout, the field is $\mathbb{R}$. The data are $N \geq 1$ points $\mathbf{x}_1, \dots, \mathbf{x}_N \in \mathbb{R}^n$, written as the columns of a matrix, and $\|\cdot\|$ is the Euclidean norm.

23.10.1 Centering

An **affine subspace** of $\mathbb{R}^n$ is a coset $A = \mathbf{p} + U = \{\mathbf{p} + \mathbf{z} : \mathbf{z} \in U\}$ of a subspace U, and its dimension is $\dim U$; Chapter 17 §01 calls U the direction space and shows in Proposition 17.1.4 that every affine hull has this form. The subspaces of $\mathbb{R}^n$ are the affine subspaces containing $\mathbf{0}$.

Chapter 12 §10 fitted subspaces, which all pass through $\mathbf{0}$. That is the wrong family for data: a cloud of points far from the origin is badly described by any line through the origin, and the quantity minimized is then dominated by the distance from $\mathbf{0}$ to the cloud rather than by its shape. Widening the competition to all affine subspaces fixes this, and it costs nothing: the extra freedom is used up in one place, and we can say in advance where.

Subtract the mean once, and the affine problem becomes the linear problem Chapter 12 solved.

Definition 23.10.1 — Data matrix, mean and centered data matrix

Let $\mathbf{x}_1, \dots, \mathbf{x}_N \in \mathbb{R}^n$. The **data matrix** is the matrix $\mathbf{X} \in M_{n \times N}(\mathbb{R})$ whose j-th **column** is $\mathbf{x}_j$. The **mean** of the data is

$$\bar{\mathbf{x}} := \frac{1}{N} \sum_{j=1}^{N} \mathbf{x}_j \in \mathbb{R}^n,$$

and the **centered data matrix** is

$$\mathbf{X}_c := \mathbf{X} - \bar{\mathbf{x}}\, \mathbf{1}^\top \in M_{n \times N}(\mathbb{R}),$$

whose j-th column is $\mathbf{c}_j := \mathbf{x}_j - \bar{\mathbf{x}}$.

Two clauses deserve comment. **Columns** are the data points, so n is the number of measured quantities and N the number of records; the opposite convention is also in use, and every formula below would be transposed under it. And $\bar{\mathbf{x}}\, \mathbf{1}^\top$ is the $n \times N$ matrix all of whose columns equal

$\bar{\mathbf{x}}$, since $\mathbf{1} \in \mathbb{R}^N$ is the all-ones vector.

The defining property of the centered matrix is that its own mean is zero:

$$\mathbf{X}_c\mathbf{1} = \mathbf{X}\mathbf{1} - \bar{\mathbf{x}}(\mathbf{1}^\top\mathbf{1}) = N\bar{\mathbf{x}} - N\bar{\mathbf{x}} = \mathbf{0},$$

using $\mathbf{1}^\top\mathbf{1} = N$. In words, each **row** of $\mathbf{X}_c$ sums to 0.

Example. (Centering three data sets)

(a) $N = 4$ points in $\mathbb{R}^2$: $(5,4), (4,1), (2,3), (1,0)$. Their sum is $(12,8)$, so $\bar{\mathbf{x}} = (3,2)$ and

$$\mathbf{X}_c = \begin{pmatrix} 2 & 1 & -1 & -2 \\ 2 & -1 & 1 & -2 \end{pmatrix}.$$

Both rows sum to 0.

(b) $N = 1$. Then $\bar{\mathbf{x}} = \mathbf{x}_1$ and $\mathbf{X}_c = \mathbf{0}$: a single point carries no shape at all. This degenerate case matters, because every ratio below has $0/0$ here and the statements must exclude it or say what they mean.

(c) Data already centered: if $\mathbf{X}\mathbf{1} = \mathbf{0}$ then $\bar{\mathbf{x}} = \mathbf{0}$ and $\mathbf{X}_c = \mathbf{X}$. Centering is idempotent, since $\mathbf{X}_c\mathbf{1} = \mathbf{0}$ always.

Change one clause and the object changes. Suppose one subtracts the mean of each *column* instead of forming the mean of the columns, replacing $\mathbf{x}_j$ by $\mathbf{x}_j - \left(\frac{1}{n}\mathbf{1}_n^\top\mathbf{x}_j\right)\mathbf{1}_n$ with $\mathbf{1}_n \in \mathbb{R}^n$. That removes the average of the measured quantities inside each record, which is a meaningful operation for some data and a meaningless one for most, and in any case is not the one below. The clause that matters is *which index is averaged over*.

23.10.2 The best-fitting affine subspace

Distances to an affine subspace reduce to distances to its direction space, and the reduction is Chapter 10's Best Approximation Theorem.

Lemma 23.10.1 — Distance to a flat, and where its translate wants to be

Let $U \subseteq \mathbb{R}^n$ be a subspace, let $Q = \mathbf{I}_n - P_U$ be the orthogonal projection onto $U^\perp$, and let $\mathbf{p} \in \mathbb{R}^n$.

(a) For every $\mathbf{x} \in \mathbb{R}^n$, $d(\mathbf{x}, \mathbf{p} + U) = \|Q(\mathbf{x} - \mathbf{p})\|$, and the nearest point of $\mathbf{p} + U$ exists.

(b) For points $\mathbf{x}_1, \dots, \mathbf{x}_N$ with mean $\bar{\mathbf{x}}$,

$$\sum_{j=1}^{N} \|Q(\mathbf{x}_j - \mathbf{p})\|^2 = \sum_{j=1}^{N} \|Q(\mathbf{x}_j - \bar{\mathbf{x}})\|^2 + N\|Q(\bar{\mathbf{x}} - \mathbf{p})\|^2.$$

In particular the left side is smallest exactly when $\bar{\mathbf{x}} \in \mathbf{p} + U$.

Idea. Part (a) is the Best Approximation Theorem after sliding the whole picture by $-\mathbf{p}$. Part (b) is the one-dimensional identity "sum of squares about a point = sum of squares about the mean + N times the squared displacement", proved the way it always is: expand the square and notice that the cross term is a multiple of $\sum_j(\mathbf{x}_j - \bar{\mathbf{x}})$, which is $\mathbf{0}$ by the definition of the mean.

Proof.

(a) A point of $\mathbf{p} + U$ is $\mathbf{p} + \mathbf{z}$ with $\mathbf{z} \in U$, and $\|\mathbf{x} - (\mathbf{p} + \mathbf{z})\| = \|(\mathbf{x} - \mathbf{p}) - \mathbf{z}\|$. By Theorem 10.3.5 the quantity $\|(\mathbf{x} - \mathbf{p}) - \mathbf{z}\|$ over $\mathbf{z} \in U$ is smallest exactly at $\mathbf{z} = P_U(\mathbf{x} - \mathbf{p})$, where its value is $\|(\mathbf{x} - \mathbf{p}) - P_U(\mathbf{x} - \mathbf{p})\| = \|Q(\mathbf{x} - \mathbf{p})\|$. So the minimum is attained and equals $\|Q(\mathbf{x} - \mathbf{p})\|$, which is $d(\mathbf{x}, \mathbf{p} + U)$ by Definition 10.3.3 applied after the translation.

(b) Put $\mathbf{y}_j = Q(\mathbf{x}_j - \bar{\mathbf{x}})$ and $\mathbf{d} = Q(\bar{\mathbf{x}} - \mathbf{p})$, so that $Q(\mathbf{x}_j - \mathbf{p}) = \mathbf{y}_j + \mathbf{d}$ by linearity of Q. Since Q is linear and $\sum_j(\mathbf{x}_j - \bar{\mathbf{x}}) = N\bar{\mathbf{x}} - N\bar{\mathbf{x}} = \mathbf{0}$,

$$\sum_j \mathbf{y}_j = Q\Big(\sum_j (\mathbf{x}_j - \bar{\mathbf{x}})\Big) = \mathbf{0}.$$

Therefore, expanding each square,

$$\begin{aligned}\sum_j \|\mathbf{y}_j + \mathbf{d}\|^2 &= \sum_j \big(\|\mathbf{y}_j\|^2 + 2\langle \mathbf{y}_j, \mathbf{d}\rangle + \|\mathbf{d}\|^2\big) \\ &= \sum_j \|\mathbf{y}_j\|^2 + 2\Big\langle \sum_j \mathbf{y}_j, \mathbf{d}\Big\rangle + N\|\mathbf{d}\|^2 \\ &= \sum_j \|\mathbf{y}_j\|^2 + N\|\mathbf{d}\|^2,\end{aligned}$$

which is the identity. The second term is ≥ 0 and vanishes exactly when $\mathbf{d} = \mathbf{0}$, that is when $\bar{\mathbf{x}} - \mathbf{p} \in \ker Q = U$ (Theorem 10.3.2), that is when $\bar{\mathbf{x}} \in \mathbf{p} + U$. This proves the lemma.

■

Part (b) is the whole of "the best affine subspace passes through the mean". It holds for **every** direction space U, before any optimization over U has happened, which is why the affine problem costs nothing extra.

Theorem 23.10.2 — The Best-Fitting Affine Subspace

Let $\mathbf{x}_1, \dots, \mathbf{x}_N \in \mathbb{R}^n$ have mean $\bar{\mathbf{x}}$ and centered data matrix $\mathbf{X}_c$ (Definition 23.10.1), let $\sigma_1 \geq \sigma_2 \geq \cdots \geq 0$ be the singular values of $\mathbf{X}_c$ (Definition 12.8.1), and let $\mathbf{u}_1, \mathbf{u}_2, \dots$ be the left singular vectors of a fixed singular value decomposition of $\mathbf{X}_c$ (Theorem 12.8.1). Let $1 \leq k \leq \min(n, N)$. Among all affine subspaces $A \subseteq \mathbb{R}^n$ of dimension at most k, the total squared distance

$$D(A) := \sum_{j=1}^{N} d(\mathbf{x}_j, A)^2$$

is smallest for

$$A_0 = \bar{\mathbf{x}} + \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k),$$

and its smallest value is $\sum_{i>k}\sigma_i^2$. Moreover **every** minimizing A contains $\bar{\mathbf{x}}$.

Idea. Two optimizations in sequence, and Lemma 23.10.1 does the outer one first. ① For a *fixed* direction space U, the best translate is the one through $\bar{\mathbf{x}}$, whatever U is. ② With the translate fixed at $\bar{\mathbf{x}}$, the objective becomes the total squared distance from the **centered** points to the subspace U — which is exactly the quantity Chapter 12 §10 minimized. So nothing new has to be proved about subspaces; the work is entirely in noticing that step ① does not interact with step ②.

Proof. Write $A=\mathbf{p}+U$ with $\dim U\le k$, and let $Q=\mathbf{I}_n-P_U$. By Lemma 23.10.1 (a),

$$D(\mathbf{p}+U)=\sum_{j}\|Q(\mathbf{x}_j-\mathbf{p})\|^2,$$

and by part (b) of the same lemma this is at least $\sum_j\|Q(\mathbf{x}_j-\bar{\mathbf{x}})\|^2=D(\bar{\mathbf{x}}+U)$, with equality exactly when $\bar{\mathbf{x}}\in\mathbf{p}+U$. So it suffices to minimize $D(\bar{\mathbf{x}}+U)$ over subspaces U with $\dim U\le k$.

Now $\|Q(\mathbf{x}_j-\bar{\mathbf{x}})\|=\|\mathbf{c}_j-P_U\mathbf{c}_j\|=d(\mathbf{c}_j,U)$ by Definition 10.3.3, where $\mathbf{c}_j=\mathbf{x}_j-\bar{\mathbf{x}}$ is the j-th column of $\mathbf{X}_c$. Hence

$$D(\bar{\mathbf{x}}+U)=\sum_{j=1}^{N}d(\mathbf{c}_j,U)^2,$$

which is the quantity $D(U)$ of Corollary 12.10.4 for the matrix $\mathbf{X}_c\in M_{n\times N}(\mathbb{R})$. That corollary, applicable because $1\le k\le\min(n,N)$, says that the minimum over $\dim U\le k$ is $\sum_{i>k}\sigma_i^2$ and is attained at $U_0=\operatorname{span}(\mathbf{u}_1,\dots,\mathbf{u}_k)$. Combining, $D(A)\ge\sum_{i>k}\sigma_i^2$ for every admissible A, with equality at $A_0=\bar{\mathbf{x}}+U_0$.

Finally let $A=\mathbf{p}+U$ be any minimizer. Then $D(\mathbf{p}+U)=D(\bar{\mathbf{x}}+U)$, since the right side is admissible and no smaller; by the equality clause of Lemma 23.10.1 (b) this forces $\bar{\mathbf{x}}\in\mathbf{p}+U=A$. This proves the theorem.

■

Quick check. Is the minimizing A_0 unique? Take the four centered points $(1,0),(-1,0),(0,1),(0,-1)$ in $\mathbb{R}^2$ and $k=1$.

Solution. No. Here $\bar{\mathbf{x}}=\mathbf{0}$ and $\mathbf{X}_c\mathbf{X}_c^{\top}=\operatorname{diag}(2,2)$, so $\sigma_1=\sigma_2=\sqrt{2}$ and the theorem's minimum is $\sigma_2^2=2$. Every line through the origin attains it: for $\operatorname{span}(\mathbf{e}_1)$ the four squared distances are $0,0,1,1$; for $\operatorname{span}\big((1,1)\big)$ each point is at squared distance $1-\tfrac12=\tfrac12$. Total 2 in both cases. What the theorem asserts is that A_0 is *a* minimizer and that $\sum_{i>k}\sigma_i^2$ is *the* minimum value; uniqueness fails exactly when $\sigma_k=\sigma_{k+1}$, just as the truncation of Definition 12.10.1 is non-unique then.

23.10.3 The sample covariance matrix

Fix a direction $\mathbf{w} \in \mathbb{R}^n$ with $\mathbf{w} \neq \mathbf{0}$ and look at the data through it: each point $\mathbf{x}_j$ has the single coordinate $t_j = \mathbf{w}^\top \mathbf{x}_j$ along $\mathbf{w}$. The mean of these numbers is

$$\frac{1}{N}\sum_j \mathbf{w}^\top \mathbf{x}_j = \mathbf{w}^\top \bar{\mathbf{x}},$$

and their spread about that mean is the number

$$\begin{aligned}\frac{1}{N}\sum_{j=1}^{N}\left(\mathbf{w}^\top \mathbf{x}_j - \mathbf{w}^\top \bar{\mathbf{x}}\right)^2 &= \frac{1}{N}\sum_{j=1}^{N}\left(\mathbf{w}^\top \mathbf{c}_j\right)^2 \\ &= \frac{1}{N}\,\mathbf{w}^\top \mathbf{X}_c \mathbf{X}_c^\top\,\mathbf{w},\end{aligned}$$

the last step because $\sum_j (\mathbf{w}^\top \mathbf{c}_j)^2 = \|\mathbf{X}_c^\top \mathbf{w}\|^2 = \mathbf{w}^\top \mathbf{X}_c \mathbf{X}_c^\top \mathbf{w}$. The direction $\mathbf{w}$ enters only through a quadratic form, and the matrix of that form does not depend on $\mathbf{w}$. That is a recurring expression, so it gets a name.

The sample covariance matrix is the single matrix that answers "how spread out are the data in direction $\mathbf{w}$*?" for every* $\mathbf{w}$ *at once.*

Definition 23.10.2 — Sample covariance matrix

Let $\mathbf{x}_1, \dots, \mathbf{x}_N \in \mathbb{R}^n$ with centered data matrix $\mathbf{X}_c$ (Definition 23.10.1). The **sample covariance matrix** of the data is

$$\mathbf{S} \coloneqq \frac{1}{N}\,\mathbf{X}_c \mathbf{X}_c^\top \in M_n(\mathbb{R}),$$

with entries

$$s_{ab} = \frac{1}{N}\sum_{j=1}^{N}(x_{aj} - \bar{x}_a)(x_{bj} - \bar{x}_b) \qquad (1 \le a, b \le n).$$

For $\mathbf{w} \in \mathbb{R}^n$ with $\mathbf{w} \neq \mathbf{0}$, the **variance of the data in the direction** $\mathbf{w}$ is the number $\mathbf{w}^\top \mathbf{S}\mathbf{w}/\|\mathbf{w}\|^2$, which for a **unit** $\mathbf{w}$ is $\mathbf{w}^\top \mathbf{S}\mathbf{w}$; and the **total variance** of the data is $\operatorname{tr} \mathbf{S}$.

Clause by clause. The factor $1/N$ makes $\mathbf{S}$ an average, so it does not grow when data are duplicated. The entry s_{aa} is the ordinary variance of the a-th measured quantity, and s_{ab} for $a \neq b$ says whether quantities a and b tend to deviate from their means in the same direction (positive) or in opposite directions (negative). The centering is inside the definition, not optional: without it the same formula would measure spread about $\mathbf{0}$ rather than about the data.

Note also what $\mathbf{S}$ does **not** depend on: the order of the columns, since the defining sum runs over all of them. It does depend on the units of each coordinate, which is the subject of the warning below.

Example. (Three covariance matrices)

(a) The four points of Example (Centering three data sets) (a). Then

$$\mathbf{X}_c \mathbf{X}_c^\top = \begin{pmatrix} 10 & 6 \\ 6 & 10 \end{pmatrix}, \qquad \mathbf{S} = \begin{pmatrix} 5/2 & 3/2 \\ 3/2 & 5/2 \end{pmatrix}.$$

Both coordinates have variance $5/2$, and the positive off-diagonal entry says they rise and fall together.

(b) Two points $\pm\mathbf{v}$ in $\mathbb{R}^n$ with $\mathbf{v} \neq \mathbf{0}$, so $N = 2$ and $\bar{\mathbf{x}} = \mathbf{0}$. Then $\mathbf{X}_c\mathbf{X}_c^\top = 2\mathbf{v}\mathbf{v}^\top$ and $\mathbf{S} = \mathbf{v}\mathbf{v}^\top$, of rank one: all the spread is in one direction, and $\mathbf{w}^\top\mathbf{S}\mathbf{w} = (\mathbf{w}^\top\mathbf{v})^2$ vanishes for every $\mathbf{w} \perp \mathbf{v}$.

(c) $N = 1$. Then $\mathbf{X}_c = \mathbf{0}$ and $\mathbf{S} = \mathbf{0}$: no direction has any spread.

Change the definition in one place and it stops being a covariance. Replacing $\mathbf{X}_c$ by $\mathbf{X}$ gives $\frac{1}{N}\mathbf{X}\mathbf{X}^\top$, whose (a, a) entry is the mean of x_{aj}^2 rather than the variance; for the data of (a) it is $\left(\begin{smallmatrix} 46/4 & 30/4 \\ 30/4 & 26/4 \end{smallmatrix}\right)$, which is not $\mathbf{S}$, and its top eigenvector is a multiple of $(1, 0.72\ldots)$ rather than of $(1, 1)$. The clause that fails is the subtraction of the mean, and with it every statement below.

Proposition 23.10.3 — The Covariance Matrix and the Singular Value Decomposition

Let $\mathbf{X}_c \in M_{n\times N}(\mathbb{R})$ be a centered data matrix with singular values $\sigma_1 \geq \sigma_2 \geq \ldots$ (padded with zeros to length n), and let $\mathbf{X}_c = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^\top$ be a singular value decomposition with columns $\mathbf{u}_1, \ldots, \mathbf{u}_n$ of $\mathbf{U}$. Put $\mathbf{S} = \frac{1}{N}\mathbf{X}_c\mathbf{X}_c^\top$. Then:

(a) $\mathbf{S}$ is symmetric and $\mathbf{S} \succeq 0$;

(b) $\mathbf{S}\mathbf{u}_i = \dfrac{\sigma_i^2}{N}\,\mathbf{u}_i$ for every i, so the eigenvalues of $\mathbf{S}$ are $\sigma_1^2/N \geq \cdots \geq \sigma_n^2/N$ and the $\mathbf{u}_i$ are an orthonormal eigenbasis;

(c) for every $\mathbf{w} \neq \mathbf{0}$, the variance of the data in the direction $\mathbf{w}$ is the Rayleigh quotient $R_{\mathbf{S}}(\mathbf{w})$ of Definition 16.1.1;

(d) $\operatorname{tr}\mathbf{S} = \dfrac{1}{N}\sum_{j=1}^{N}\|\mathbf{x}_j - \bar{\mathbf{x}}\|^2 = \dfrac{1}{N}\sum_i \sigma_i^2$.

Idea. Every part is one line once $\mathbf{X}_c = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^\top$ is written down: (a) and (b) because $\mathbf{X}_c\mathbf{X}_c^\top = \mathbf{U}(\mathbf{\Sigma}\mathbf{\Sigma}^\top)\mathbf{U}^\top$ is already a diagonalization, (c) because the computation before Definition 23.10.2 *was* the Rayleigh quotient, and (d) because the trace does not notice the unitary factors and reads the same quantity off the rows and off the columns.

Proof.

(a) $\mathbf{S}^\top = \frac{1}{N}(\mathbf{X}_c\mathbf{X}_c^\top)^\top = \frac{1}{N}\mathbf{X}_c\mathbf{X}_c^\top = \mathbf{S}$, and for every $\mathbf{w}$, $\mathbf{w}^\top\mathbf{S}\mathbf{w} = \frac{1}{N}\|\mathbf{X}_c^\top\mathbf{w}\|^2 \geq 0$; with symmetry this is Definition 12.1.1.

(b) Since $\mathbf{V}$ is orthogonal, $\mathbf{V}^\top\mathbf{V} = \mathbf{I}_N$, so

$$\mathbf{X}_c\mathbf{X}_c^\top = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^\top\mathbf{V}\mathbf{\Sigma}^\top\mathbf{U}^\top = \mathbf{U}(\mathbf{\Sigma}\mathbf{\Sigma}^\top)\mathbf{U}^\top,$$

and $\mathbf{\Sigma}\mathbf{\Sigma}^\top = \operatorname{diag}(\sigma_1^2, \ldots, \sigma_n^2)$ by the shape of $\mathbf{\Sigma}$ in Theorem 12.8.1. Multiplying on the right by $\mathbf{u}_i$ and using $\mathbf{U}^\top\mathbf{u}_i = \mathbf{e}_i$ gives $\mathbf{X}_c\mathbf{X}_c^\top\mathbf{u}_i = \sigma_i^2\mathbf{u}_i$; divide by N. The $\mathbf{u}_i$ are orthonormal and there are n of them, so they are an orthonormal basis of $\mathbb{R}^n$, and the list σ_i^2/N is decreasing.

(c) By the computation preceding Definition 23.10.2, the variance in direction $\mathbf{w}$ is $\mathbf{w}^\top\mathbf{S}\mathbf{w}/\|\mathbf{w}\|^2$. Since $\mathbf{S}$ is symmetric, $R_{\mathbf{S}}(\mathbf{w}) = \langle\mathbf{S}\mathbf{w}, \mathbf{w}\rangle/\langle\mathbf{w}, \mathbf{w}\rangle = \mathbf{w}^\top\mathbf{S}\mathbf{w}/\|\mathbf{w}\|^2$ by Definition 16.1.1, which is the same number.

(d) The j-th diagonal entry of $\mathbf{X}_c^\top\mathbf{X}_c$ is $\|\mathbf{c}_j\|^2$, so $\operatorname{tr}(\mathbf{X}_c^\top\mathbf{X}_c) = \sum_j\|\mathbf{c}_j\|^2$; and $\operatorname{tr}(\mathbf{X}_c\mathbf{X}_c^\top) =$

$\operatorname{tr}(\mathbf{X}_c^\top \mathbf{X}_c)$ by Theorem 0.9.6 (3). On the other hand the display in (b) and the same trace identity give

$$\begin{aligned}\operatorname{tr}(\mathbf{X}_c \mathbf{X}_c^\top) &= \operatorname{tr}\big(\mathbf{U}(\mathbf{\Sigma}\mathbf{\Sigma}^\top)\mathbf{U}^\top\big) \\ &= \operatorname{tr}\big((\mathbf{\Sigma}\mathbf{\Sigma}^\top)\mathbf{U}^\top\mathbf{U}\big) = \sum_i \sigma_i^2,\end{aligned}$$

using $\mathbf{U}^\top\mathbf{U} = \mathbf{I}_n$. Dividing by N gives both equalities. This proves the proposition.

■

Part (c) connects this section to Chapter 16. The question "which direction has the most spread?" is the question "where is $R_{\mathbf{S}}$ largest?", and Proposition 16.1.1 answers it: the maximum is $\lambda_1(\mathbf{S}) = \sigma_1^2/N$, attained at $\mathbf{u}_1$. "Which direction has the most spread among those orthogonal to $\mathbf{u}_1, \dots, \mathbf{u}_{k-1}$?" is answered the same way by Proposition 16.1.3, with maximum σ_k^2/N at $\mathbf{u}_k$. So the leading left singular vectors are not only the best-fitting directions of Theorem 23.10.2; they are also, one at a time, the directions of greatest remaining spread. The two descriptions agree because they are the two halves of one Pythagorean identity, which is the next theorem.

Definition 23.10.3 — Principal directions and components

In the situation of Proposition 23.10.3, the unit vectors $\mathbf{u}_1, \mathbf{u}_2, \dots$ are the **principal directions** of the data, and the numbers $\mathbf{u}_i^\top \mathbf{c}_1, \dots, \mathbf{u}_i^\top \mathbf{c}_N$ are the i-th **principal components**: the coordinates of the centered data along $\mathbf{u}_i$.

23.10.4 How much variance a subspace explains

Theorem 23.10.4 — Variance Captured by the Principal Directions

In the situation of Proposition 23.10.3, let $1 \le k \le \min(n, N)$, let $U_0 = \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$ and let P be the orthogonal projection onto a subspace U with $\dim U \le k$. Write

$$\operatorname{var}(U) := \frac{1}{N}\sum_{j=1}^{N} \|P(\mathbf{x}_j - \bar{\mathbf{x}})\|^2.$$

Then:

(a) $\operatorname{var}(U)$ is the total variance of the projected points $P\mathbf{x}_1, \dots, P\mathbf{x}_N$, whose mean is $P\bar{\mathbf{x}}$;

(b) $\operatorname{var}(U) + \dfrac{1}{N} D(\bar{\mathbf{x}} + U) = \operatorname{tr} \mathbf{S}$, where D is as in Theorem 23.10.2;

(c) $\operatorname{var}(U) \le \operatorname{var}(U_0) = \dfrac{1}{N}\sum_{i \le k} \sigma_i^2$;

(d) if $\mathbf{X}_c \neq \mathbf{0}$, the fraction of the total variance captured by U_0 is

$$\frac{\operatorname{var}(U_0)}{\operatorname{tr} \mathbf{S}} = \frac{\sigma_1^2 + \cdots + \sigma_k^2}{\sigma_1^2 + \sigma_2^2 + \dots}.$$

Idea. Everything is Pythagoras applied N times and then added up. For each centered point, $\|\mathbf{c}_j\|^2$ splits into the part P keeps and the part it throws away; averaging the first over j is $\operatorname{var}(U)$, averaging the second is the fitting error of Theorem 23.10.2, and averaging the total is $\operatorname{tr}\mathbf{S}$ by Proposition 23.10.3 (d). Once (b) is available, (c) and (d) are just the theorem already proved, divided by N.

Proof.

(a) The mean of $P\mathbf{x}_1, \dots, P\mathbf{x}_N$ is $\frac{1}{N}\sum_j P\mathbf{x}_j = P\bar{\mathbf{x}}$ by linearity of P, so the j-th centered projected point is $P\mathbf{x}_j - P\bar{\mathbf{x}} = P\mathbf{c}_j$. By Proposition 23.10.3 (d) applied to these N points, their total variance is $\frac{1}{N}\sum_j \|P\mathbf{c}_j\|^2 = \operatorname{var}(U)$.

(b) Fix j. The vectors $P\mathbf{c}_j$ and $\mathbf{c}_j - P\mathbf{c}_j$ are orthogonal, the first lying in U and the second in $U^\perp$ (Theorem 10.3.2), so Theorem 10.1.3 gives

$$\|\mathbf{c}_j\|^2 = \|P\mathbf{c}_j\|^2 + \|\mathbf{c}_j - P\mathbf{c}_j\|^2.$$

Summing over j and dividing by N: the left side is $\operatorname{tr}\mathbf{S}$ by Proposition 23.10.3 (d), the first term on the right is $\operatorname{var}(U)$, and the second is $\frac{1}{N}\sum_j d(\mathbf{c}_j, U)^2 = \frac{1}{N}D(\bar{\mathbf{x}} + U)$, as computed in the proof of Theorem 23.10.2.

(c) By (b), maximizing $\operatorname{var}(U)$ over $\dim U \le k$ is the same as minimizing $D(\bar{\mathbf{x}}+U)$, and Theorem 23.10.2 says the minimum is $\sum_{i>k}\sigma_i^2$, attained at U_0. Hence $\operatorname{var}(U) \le \operatorname{var}(U_0)$, and by (b) again,

$$\begin{aligned}\operatorname{var}(U_0) &= \operatorname{tr}\mathbf{S} - \frac{1}{N}\sum_{i>k}\sigma_i^2 \\ &= \frac{1}{N}\sum_i \sigma_i^2 - \frac{1}{N}\sum_{i>k}\sigma_i^2 = \frac{1}{N}\sum_{i\le k}\sigma_i^2.\end{aligned}$$

(d) If $\mathbf{X}_c \neq \mathbf{0}$ then some $\sigma_i > 0$, so $\operatorname{tr}\mathbf{S} = \frac{1}{N}\sum_i \sigma_i^2 > 0$ and the quotient is defined; dividing the value in (c) by it cancels the $1/N$. This proves the theorem.

■

So "the first k principal directions explain $\left(\sum_{i\le k}\sigma_i^2\right)/\left(\sum_i \sigma_i^2\right)$ of the variance" is a theorem about the N given points, not a convention: the numerator is the variance of the projected cloud, the denominator is the variance of the original cloud, and part (b) is what makes the two add up with nothing left over.

Example. (Four points, done exactly)

Take the four points $(5,4), (4,1), (2,3), (1,0)$ of Example (Centering three data sets) (a). Find the mean, the sample covariance matrix, the principal directions, the best-fitting line, the total squared distance to it, and the fraction of variance it explains.

Solution. Mean and centering. $\bar{\mathbf{x}} = (3,2)$, and $\mathbf{X}_c$ has columns $(2,2), (1,-1), (-1,1), (-2,-2)$, as computed above.

Covariance. $\mathbf{X}_c\mathbf{X}_c^\top = \left(\begin{smallmatrix}10 & 6\\ 6 & 10\end{smallmatrix}\right)$, so $\mathbf{S} = \left(\begin{smallmatrix}5/2 & 3/2\\ 3/2 & 5/2\end{smallmatrix}\right)$. Since $\mathbf{X}_c\mathbf{X}_c^\top$ has the form $a\mathbf{I} + b\mathbf{J}$ it

sends $(1,1)$ to $16(1,1)$ and $(1,-1)$ to $4(1,-1)$, so its eigenvalues are 16 and 4 with

$$\mathbf{u}_1 = \tfrac{1}{\sqrt{2}}(1,1), \qquad \mathbf{u}_2 = \tfrac{1}{\sqrt{2}}(1,-1).$$

By Proposition 23.10.3 (b), $\sigma_1^2 = 16$ and $\sigma_2^2 = 4$, that is $\sigma_1 = 4$ and $\sigma_2 = 2$, and the eigenvalues of $\mathbf{S}$ are 4 and 1. Check: $\operatorname{tr}\mathbf{S} = 5$ and $4 + 1 = 5$.

Total variance, two ways. The squared distances of the centered points from $\mathbf{0}$ are $8, 2, 2, 8$, of average 5. And $\frac{1}{N}\sum_i \sigma_i^2 = \frac{1}{4}(16+4) = 5$, as Proposition 23.10.3 (d) requires.

Best-fitting line. By Theorem 23.10.2 with $k = 1$ it is

$$A_0 = (3,2) + \operatorname{span}\big((1,1)\big),$$

the line $y = x - 1$, and the total squared distance is $\sigma_2^2 = 4$. Directly: $(5,4)$ and $(1,0)$ lie on the line, contributing 0; for $(4,1)$ the centered point is $(1,-1)$, whose projection onto $\operatorname{span}\big((1,1)\big)$ is $\mathbf{0}$, so its squared distance is 2; likewise 2 for $(2,3)$. Total 4, as predicted.

Variance explained. $\operatorname{var}(U_0) = \frac{1}{4}\sigma_1^2 = 4$, out of $\operatorname{tr}\mathbf{S} = 5$: the first principal direction explains $16/20 = 80\%$ of the variance, and the remaining 20% is the average squared distance $4/4 = 1$ to the line. The two add to 5, which is Theorem 23.10.4 (b).

Warning. **Principal directions are not "the important directions": they change when you change the units.** Take the four centered points $(1,0), (-1,0), (0,2), (0,-2)$. Then $\mathbf{X}_c\mathbf{X}_c^\top = \operatorname{diag}(2,8)$, so the first principal direction is $\mathbf{e}_2$. Now suppose the first coordinate was measured in meters and we re-express it in units three times smaller, which multiplies row 1 by 3. The data are the same data; the new centered matrix is $\mathbf{D}\mathbf{X}_c$ with $\mathbf{D} = \operatorname{diag}(3,1)$, and

$$(\mathbf{D}\mathbf{X}_c)(\mathbf{D}\mathbf{X}_c)^\top = \mathbf{D}\,\operatorname{diag}(2,8)\,\mathbf{D} = \operatorname{diag}(18,8),$$

so the first principal direction is now $\mathbf{e}_1$. It has turned by a right angle because of a choice of units. Nothing is wrong with the theorem — $\mathbf{D}\mathbf{X}_c$ really is a different matrix — but "the direction of greatest variance" is a statement about a coordinate system, not about the data alone. Rescaling each coordinate to variance 1 before starting is one common repair; it is a modeling decision, and it is not forced by anything proved here.

23.10.5 Computing it, and what is not proved

Two closing matters, one computational and one about scope.

Never form $\mathbf{X}_c\mathbf{X}_c^\top$. Everything above is stated in terms of $\mathbf{S}$, and $\mathbf{S}$ is the natural object to state it with; but forming $\mathbf{S}$ and then finding its eigenvalues is the worst available way to compute the principal directions. The reason is Theorem 15.8.4: passing from $\mathbf{A}$ to $\mathbf{A}^*\mathbf{A}$ squares the condition number, $\kappa_2(\mathbf{A}^*\mathbf{A}) = \kappa_2(\mathbf{A})^2$, and Section 3 of this chapter turns that into a count of lost digits — Theorem 23.3.2 says the product route loses about $2\log_{10}\kappa_2$ decimal digits where a backward stable factorization of $\mathbf{A}$ itself loses about $\log_{10}\kappa_2$. The same arithmetic applies with $\mathbf{A} = \mathbf{X}_c^\top$ — but only when that matrix has full column rank, which is the hypothesis of Theorem 15.8.4. That asks for $\operatorname{rank}\mathbf{X}_c = n$, and $\mathbf{X}_c\mathbf{1} = \mathbf{0}$ already forces $\operatorname{rank}\mathbf{X}_c \le N - 1$, so it fails whenever $N \le n$: for three records of ten measured quantities there is nothing to apply. The count that follows needs no hypothesis on the rank, and it is the one to remember.

Here is the count in this setting. Each entry of $\mathbf{X}_c\mathbf{X}_c^\top$ is an inner product of two rows, each of length N, so by Theorem 23.1.2 the computed product is $\mathbf{X}_c\mathbf{X}_c^\top + \mathbf{\Delta}$ with $\|\mathbf{\Delta}\|_2$ of order $c(n,N)\,u\,\sigma_1^2$, where u is the unit roundoff of Section 1 and c is a modest dimensional factor. It is a factor and not a constant because the entrywise bound has to be aggregated over the whole $n \times n$ product, by the same count as in Section 3, where the corresponding step reads $\|\mathbf{C} - \mathbf{A}^*\mathbf{A}\| \le \gamma_m\|\mathbf{A}\|_F^2 \le n\gamma_m\|\mathbf{A}\|^2$: the length of the inner products sits inside γ, and passing from the Frobenius norm to the spectral norm puts their number in front. Here that makes $c(n,N)$ of size about nN.

If the implementation forms only the upper triangle and reflects it — an assumption about the computation, not something proved here — then $\mathbf{\Delta}$ is symmetric, and Corollary 16.3.6 says a symmetric perturbation of that size moves every eigenvalue by at most $\|\mathbf{\Delta}\|_2$. So every σ_i^2 below $c(n,N)\,u\,\sigma_1^2$ — that is, up to the factor $\sqrt{c}$, every σ_i below $\sqrt{u}\,\sigma_1$ — is indistinguishable from 0 in the computed product, while a backward stable factorization of $\mathbf{X}_c$ itself keeps it. Those are exactly the singular values a low-rank fit has to decide about. The right computation therefore works on $\mathbf{X}_c$ directly and never builds the product.

What this chapter does **not** do is assemble that computation. The ingredients are here — the Householder reductions of Section 3, the shifted **QR** iteration of Section 5 — but no algorithm for the singular values of a given matrix is written down or analyzed anywhere in this book. So the paragraph above pays the parenthesis of the last clause of Chapter 12 §10's promise, that a singular value decomposition is "never" computed by forming $\mathbf{A}^*\mathbf{A}$ and finding its eigenvalues; the clause itself, how one is actually computed for a large matrix, is left unpaid.

The finite population, and the boundary. Chapter 12 §10 said that the statistics needs "a probabilistic model, a reason to prefer squared error, and an argument that the sample answer says something about the population". Here is exactly what has been delivered.

A probabilistic model, for the finite population of the data themselves. Regard the N columns as a population of N equally likely outcomes, each of weight $1/N$. Then "expectation" means the average $\frac{1}{N}\sum_j$, which needs no measure theory and no limit, and the mean of the population is $\bar{\mathbf{x}}$. For two real-valued quantities f, g on it, with averages $\bar f = \frac{1}{N}\sum_j f(\mathbf{x}_j)$ and $\bar g = \frac{1}{N}\sum_j g(\mathbf{x}_j)$, the **covariance** of the population is

$$\operatorname{Cov}(f,g) \coloneqq \frac{1}{N}\sum_{j=1}^{N}\big(f(\mathbf{x}_j) - \bar f\big)\big(g(\mathbf{x}_j) - \bar g\big),$$

and the variance of f is $\operatorname{Cov}(f,f)$. With that reading, the variance of $\mathbf{x} \mapsto \mathbf{w}^\top\mathbf{x}$ is $\mathbf{w}^\top\mathbf{S}\mathbf{w}$, which for a **unit** $\mathbf{w}$ is the variance in the direction $\mathbf{w}$ of Definition 23.10.2, hence the Rayleigh quotient of Proposition 23.10.3 (c); and the covariance of $\mathbf{x} \mapsto x_a$ with $\mathbf{x} \mapsto x_b$ is s_{ab}, which is the displayed formula of Definition 23.10.2 read backwards. So $\mathbf{S}$ **is** the covariance matrix of that population, and Theorem 23.10.4 is a statement about it. This much is a theorem, and it is what was proved above.

A reason to prefer squared error. Three, none of them a proof that squared error is the right criterion, which is a modeling question. (i) It does not depend on the coordinate frame: an orthogonal change of coordinates is an isometry, so it leaves every distance $d(\mathbf{x}_j, A)$, hence $D(A)$, unchanged. The largest entry of the error has no such property — the matrix $\operatorname{diag}(1,0)$ has largest entry 1, while the same matrix read in the frame $\frac{1}{\sqrt2}(1,\pm1)$ is $\frac{1}{2}\left(\begin{smallmatrix}1&1\\1&1\end{smallmatrix}\right)$, with largest entry $\frac12$ — and Chapter 12 §10's warning shows that it really does prefer a different answer. (ii) It splits: Theorem 23.10.4 (b) says captured plus lost equals total, exactly, which is what makes a *fraction* of variance meaningful at all. (iii) It has a closed-form minimizer, computable by a single factorization (Theorem 12.10.3); for the sum of **unsquared** distances $\sum_j d(\mathbf{x}_j, A)$,

nothing proved in this book produces a minimizer at all.

An argument that the sample says something about a larger population. This is **not** proved here, and it cannot be with the tools of this book. Such an argument requires a probability model in which the N points are drawn from a distribution on $\mathbb{R}^n$, an expectation defined by an integral rather than a finite sum, and theorems saying that $\mathbf{S}$ converges to the distribution's covariance and that its eigenvectors converge to the distribution's principal directions. Every one of those belongs to probability and statistics, which this book does not develop. Chapter 12 §10's sentence promised it; the honest correction is that linear algebra supplies the finite-population model and the reasons for squared error, and hands the inference to a subject this book does not enter.

Remark. **The divisor N versus $N-1$.** Statistics usually defines the sample covariance with $1/(N-1)$, which presupposes $N \geq 2$, because that makes it an unbiased estimator of a population covariance — a statement inside the probability model just excluded, and one we therefore cannot prove. With the finite-population reading the divisor is N, and that is the convention of Definition 23.10.2, which makes sense for every $N \geq 1$. For $N \geq 2$ the choice changes nothing here: it multiplies $\mathbf{S}$ by $N/(N-1)$, which scales every eigenvalue by the same factor, changes no eigenvector, and leaves every ratio such as Theorem 23.10.4 (d) exactly as it was.

23.10.6 Exercises

23.10.6.1 A. Check your understanding

Exercise A1.

(a) Define the centered data matrix and the sample covariance matrix, and say what $\mathbf{w}^\top \mathbf{S}\mathbf{w}$ means for a unit vector $\mathbf{w}$.

(b) State Theorem 23.10.2, including the value of the minimum and the claim about the mean.

(c) True or false: the principal directions of a data set are the eigenvectors of $\mathbf{X}\mathbf{X}^\top$. Justify your answer.

(d) True or false: if $N = 3$ points in $\mathbb{R}^{10}$ are given, then $\mathbf{S}$ has rank at most 2. Justify your answer.

(e) Why should a computation of the principal directions avoid forming $\mathbf{X}_c\mathbf{X}_c^\top$?

Solution.

(a) $\mathbf{X}_c = \mathbf{X} - \bar{\mathbf{x}}\mathbf{1}^\top$, the data matrix with the mean column subtracted from every column, and $\mathbf{S} = \frac{1}{N}\mathbf{X}_c\mathbf{X}_c^\top$ (Definition 23.10.1, Definition 23.10.2). For a unit $\mathbf{w}$, $\mathbf{w}^\top \mathbf{S}\mathbf{w}$ is the variance of the N numbers $\mathbf{w}^\top \mathbf{x}_j$, that is the spread of the data in the direction $\mathbf{w}$.

(b) Among all affine subspaces of $\mathbb{R}^n$ of dimension at most $k \leq \min(n, N)$, the total squared distance $\sum_j d(\mathbf{x}_j, A)^2$ is smallest at $A_0 = \bar{\mathbf{x}} + \operatorname{span}(\mathbf{u}_1, \dots, \mathbf{u}_k)$, the minimum value is $\sum_{i>k} \sigma_i^2$ with σ_i the singular values of $\mathbf{X}_c$, and every minimizer contains $\bar{\mathbf{x}}$.

(c) False in general; they are the eigenvectors of $\mathbf{X}_c\mathbf{X}_c^\top$. For the four points of Example (Four points, done exactly), $\mathbf{X}\mathbf{X}^\top = \left(\begin{smallmatrix} 46 & 30 \\ 30 & 26 \end{smallmatrix}\right)$, whose eigenvalues are $36 \pm 10\sqrt{10}$

and whose top eigenvector is not $(1,1)$, while the top principal direction is. The two **matrices** agree exactly when $\bar{\mathbf{x}} = \mathbf{0}$, since $\mathbf{X}\mathbf{X}^\top = \mathbf{X}_c\mathbf{X}_c^\top + N\bar{\mathbf{x}}\bar{\mathbf{x}}^\top$. Their **eigenvectors** can agree without that: for the two points $(0,0)$ and $(2,0)$ the mean is $(1,0) \neq \mathbf{0}$, yet $\mathbf{X}\mathbf{X}^\top = \operatorname{diag}(4,0)$ and $\mathbf{X}_c\mathbf{X}_c^\top = \operatorname{diag}(2,0)$ have the same eigenvectors.

(d) True. $\operatorname{rank}\mathbf{S} = \operatorname{rank}\mathbf{X}_c$ — since $\operatorname{nul}(\mathbf{X}_c^\top) = \operatorname{nul}(\mathbf{X}_c\mathbf{X}_c^\top)$, because $\mathbf{X}_c\mathbf{X}_c^\top\mathbf{w} = \mathbf{0}$ gives $\|\mathbf{X}_c^\top\mathbf{w}\|^2 = \mathbf{w}^\top\mathbf{X}_c\mathbf{X}_c^\top\mathbf{w} = 0$ — and $\mathbf{X}_c\mathbf{1} = \mathbf{0}$ with $\mathbf{X}_c$ having 3 columns forces $\operatorname{rank}\mathbf{X}_c \leq 2$. Centering costs at most one from the rank and sometimes nothing:

$$\operatorname{rank}\mathbf{X} - 1 \;\leq\; \operatorname{rank}\mathbf{X}_c \;\leq\; \operatorname{rank}\mathbf{X},$$

the right inequality because $\mathbf{X}_c = \mathbf{X}(\mathbf{I}_N - \frac{1}{N}\mathbf{1}\mathbf{1}^\top)$ is a product (Theorem 2.5.9), the left because $\mathbf{X} = \mathbf{X}_c + \bar{\mathbf{x}}\mathbf{1}^\top$ adds to it a matrix of rank at most 1 (Exercise (C1: Rank of a sum)). The drop need not happen: for $\mathbf{x}_1 = (1,0)$, $\mathbf{x}_2 = (2,0)$, $\mathbf{x}_3 = (0,1)$ the mean is $(1, \frac{1}{3}) \neq \mathbf{0}$, yet $\operatorname{rank}\mathbf{X} = \operatorname{rank}\mathbf{X}_c = 2$.

(e) Because forming the product destroys the small singular values. Each entry of $\mathbf{X}_c\mathbf{X}_c^\top$ is an inner product, so the computed product is $\mathbf{X}_c\mathbf{X}_c^\top + \mathbf{\Delta}$ with $\|\mathbf{\Delta}\|_2$ of order $c(n,N)\,u\,\sigma_1^2$ (Theorem 23.1.2); if $\mathbf{\Delta}$ is symmetric, Corollary 16.3.6 moves every eigenvalue by at most that, so every σ_i below about $\sqrt{u}\,\sigma_1$ becomes indistinguishable from 0, while a backward stable factorization of $\mathbf{X}_c$ itself keeps it — and those are exactly the singular values a low-rank fit has to decide about. The conditioning statement $\kappa_2(\mathbf{X}_c\mathbf{X}_c^\top) = \kappa_2(\mathbf{X}_c)^2$ says the same thing in digits (Theorem 15.8.4, Theorem 23.3.2), but it needs $\mathbf{X}_c^\top$ to have full column rank, which fails in part (d) above; the Weyl count needs no hypothesis on the rank.

23.10.6.2 B. Practice

Exercise B1: A four-point cloud.

The points $(1,1), (3,5), (5,3), (7,7)$ are given in $\mathbb{R}^2$.

(a) Compute $\bar{\mathbf{x}}$, $\mathbf{X}_c$, $\mathbf{X}_c\mathbf{X}_c^\top$ and $\mathbf{S}$.

(b) Find the singular values of $\mathbf{X}_c$ and the principal directions.

(c) Find the best-fitting line, the total squared distance to it, and the fraction of variance it explains. Verify the total squared distance directly.

Solution.

(a) The sum of the four points is $(16,16)$, so $\bar{\mathbf{x}} = (4,4)$ and

$$\mathbf{X}_c = \begin{pmatrix} -3 & -1 & 1 & 3 \\ -3 & 1 & -1 & 3 \end{pmatrix}, \qquad \mathbf{X}_c\mathbf{X}_c^\top = \begin{pmatrix} 20 & 16 \\ 16 & 20 \end{pmatrix},$$

so $\mathbf{S} = \left(\begin{smallmatrix} 5 & 4 \\ 4 & 5 \end{smallmatrix}\right)$.

(b) $\mathbf{X}_c\mathbf{X}_c^\top$ sends $(1,1)$ to $36(1,1)$ and $(1,-1)$ to $4(1,-1)$, so $\sigma_1^2 = 36$, $\sigma_2^2 = 4$, that is $\sigma_1 = 6$, $\sigma_2 = 2$, with $\mathbf{u}_1 = \frac{1}{\sqrt{2}}(1,1)$ and $\mathbf{u}_2 = \frac{1}{\sqrt{2}}(1,-1)$. The eigenvalues of $\mathbf{S}$ are 9 and 1, which are $\sigma_i^2/4$ (Proposition 23.10.3 (b)).

(c) By Theorem 23.10.2 the best line is $(4,4) + \operatorname{span}\big((1,1)\big)$, that is $y = x$, with total squared distance $\sigma_2^2 = 4$. By Theorem 23.10.4 (d) it explains $36/40 = 90\%$ of the variance. Directly: $(1,1)$ and $(7,7)$ lie on $y = x$; the centered points $(-1,1)$ and

$(1,-1)$ both project to $\mathbf{0}$ on $\operatorname{span}\big((1,1)\big)$, so each contributes 2. Total 4.

Exercise B2: Variance direction by direction.

For the data of Exercise B1, compute the variance in the directions $\mathbf{e}_1$, $\mathbf{e}_2$, $\frac{1}{\sqrt{2}}(1,1)$ and $\frac{1}{\sqrt{2}}(1,-1)$, and say which of them is largest and why that was predictable.

Solution. With $\mathbf{S} = \left(\begin{smallmatrix} 5 & 4 \\ 4 & 5 \end{smallmatrix}\right)$ and Definition 23.10.2, the variance in a unit direction $\mathbf{w}$ is $\mathbf{w}^{\top}\mathbf{S}\mathbf{w}$:

$$\mathbf{e}_1 \mapsto 5, \quad \mathbf{e}_2 \mapsto 5, \quad \tfrac{(1,1)}{\sqrt{2}} \mapsto 9, \quad \tfrac{(1,-1)}{\sqrt{2}} \mapsto 1.$$

The largest is 9, in the direction $\mathbf{u}_1$. This was predictable from Proposition 23.10.3 (c) and Proposition 16.1.1: the variance in a unit direction is the Rayleigh quotient of $\mathbf{S}$, whose maximum is $\lambda_1(\mathbf{S}) = 9$ and is attained at a unit eigenvector for λ_1. Note also $5 + 5 = 9 + 1 = \operatorname{tr}\mathbf{S}$: the total variance is the same however the orthonormal frame is chosen.

Exercise B3: Changing the units.

The centered data matrix of a two-coordinate data set is $\mathbf{X}_c = \left(\begin{smallmatrix} 3 & -3 & 0 & 0 \\ 0 & 0 & 4 & -4 \end{smallmatrix}\right)$. The second coordinate is then re-expressed in units c times smaller, which multiplies row 2 by $c > 0$.

(a) Find the principal directions before the change.

(b) Find the value of c at which the first principal direction switches from one coordinate axis to the other, and say what happens exactly at that value.

Solution.

(a) $\mathbf{X}_c\mathbf{X}_c^{\top} = \operatorname{diag}(18, 32)$, so the principal directions are $\mathbf{u}_1 = \mathbf{e}_2$ (variance $32/4 = 8$) and $\mathbf{u}_2 = \mathbf{e}_1$ (variance $18/4 = 4.5$).

(b) After the change the centered matrix is $\mathbf{D}\mathbf{X}_c$ with $\mathbf{D} = \operatorname{diag}(1, c)$, and $(\mathbf{D}\mathbf{X}_c)(\mathbf{D}\mathbf{X}_c)^{\top} = \operatorname{diag}(18, 32c^2)$. The first principal direction is $\mathbf{e}_2$ when $32c^2 > 18$, that is $c > 3/4$, and $\mathbf{e}_1$ when $c < 3/4$. At $c = 3/4$ the two eigenvalues are equal, $\sigma_1 = \sigma_2$, and **every** direction is a direction of greatest variance: the principal directions are not determined at all, and the best-fitting line of Theorem 23.10.2 is not unique, exactly as in the Quick check above.

23.10.6.3 C. Going deeper

Exercise C1: The mean is forced, and the projection is not a shortcut.

Let $\mathbf{x}_1, \dots, \mathbf{x}_N \in \mathbb{R}^n$ with mean $\bar{\mathbf{x}}$.

(a) Prove that the point $\mathbf{p} \in \mathbb{R}^n$ minimizing $\sum_j \|\mathbf{x}_j - \mathbf{p}\|^2$ is unique and equals $\bar{\mathbf{x}}$. (This is the case $k = 0$, which Theorem 23.10.2 excludes, so it has to be proved rather than quoted.)

(b) Hence deduce that for every subspace U, the affine subspace $\mathbf{p} + U$ minimizing D over translates of U is $\bar{\mathbf{x}} + U$.

(c) Give an example of data and a subspace U for which $\bar{\mathbf{x}} + U$ is **not** the best-fitting affine subspace of its dimension, so that the choice of U still matters.

Solution.

(a) Apply Lemma 23.10.1 (b) with $U = \{\mathbf{0}\}$, so that $Q = \mathbf{I}_n$:

$$\sum_j \|\mathbf{x}_j - \mathbf{p}\|^2 = \sum_j \|\mathbf{x}_j - \bar{\mathbf{x}}\|^2 + N\|\bar{\mathbf{x}} - \mathbf{p}\|^2.$$

The first term does not depend on $\mathbf{p}$ and the second is ≥ 0, vanishing exactly when $\mathbf{p} = \bar{\mathbf{x}}$. So the minimum is attained at $\bar{\mathbf{x}}$ and nowhere else.

(b) By Lemma 23.10.1 (a), $D(\mathbf{p}+U) = \sum_j \|Q(\mathbf{x}_j - \mathbf{p})\|^2$, and by part (b) of that lemma this exceeds $D(\bar{\mathbf{x}} + U)$ unless $\bar{\mathbf{x}} \in \mathbf{p} + U$ — in which case $\mathbf{p} + U = \bar{\mathbf{x}} + U$, the two cosets having a common point and the same direction space. So the minimizing translate is $\bar{\mathbf{x}} + U$, and as a set it is unique.

(c) Take the four points of Example (Four points, done exactly) and $U = \operatorname{span}(\mathbf{e}_1)$. Then $\bar{\mathbf{x}}+U$ is the horizontal line $y = 2$, and the centered points $(2,2), (1,-1), (-1,1), (-2,-2)$ are at squared distances $4, 1, 1, 4$ from U, total 10. The best line is $\bar{\mathbf{x}}+\operatorname{span}\big((1,1)\big)$, with total 4. Both pass through the mean; only one has the right direction. Choosing the translate is free, choosing the direction space is the whole problem.

Exercise C2: Total variance is a trace, and what that buys.

Let $\mathbf{x}_1, \dots, \mathbf{x}_N \in \mathbb{R}^n$ with sample covariance $\mathbf{S}$, and let $\mathbf{Q} \in M_n(\mathbb{R})$ be orthogonal.

(a) Prove that the data $\mathbf{Q}\mathbf{x}_1, \dots, \mathbf{Q}\mathbf{x}_N$ have sample covariance $\mathbf{Q}\mathbf{S}\mathbf{Q}^\top$, and deduce that the total variance $\operatorname{tr}\mathbf{S}$ is unchanged.

(b) Prove that for any orthonormal basis $(\mathbf{q}_1, \dots, \mathbf{q}_n)$ of $\mathbb{R}^n$, the sum of the variances of the data in the n directions $\mathbf{q}_i$ equals $\operatorname{tr}\mathbf{S}$.

(c) Deduce that no orthonormal frame can make every coordinate variance small: some $\mathbf{q}_i$ always has variance at least $\operatorname{tr}\mathbf{S}/n$. For the data of Example (Four points, done exactly), which frames attain that bound?

Solution.

(a) The mean of the transformed data is $\frac{1}{N}\sum_j \mathbf{Q}\mathbf{x}_j = \mathbf{Q}\bar{\mathbf{x}}$, so the transformed centered matrix is $\mathbf{Q}\mathbf{X} - \mathbf{Q}\bar{\mathbf{x}}\mathbf{1}^\top = \mathbf{Q}\mathbf{X}_c$. Hence its sample covariance is $\frac{1}{N}(\mathbf{Q}\mathbf{X}_c)(\mathbf{Q}\mathbf{X}_c)^\top = \mathbf{Q}\mathbf{S}\mathbf{Q}^\top$. By Theorem 0.9.6, $\operatorname{tr}(\mathbf{Q}\mathbf{S}\mathbf{Q}^\top) = \operatorname{tr}(\mathbf{S}\mathbf{Q}^\top\mathbf{Q}) = \operatorname{tr}\mathbf{S}$, since $\mathbf{Q}^\top\mathbf{Q} = \mathbf{I}_n$.

(b) By Definition 23.10.2 the variance in the unit direction $\mathbf{q}_i$ is $\mathbf{q}_i^\top\mathbf{S}\mathbf{q}_i$. Let $\mathbf{Q}$ be the orthogonal matrix with columns $\mathbf{q}_1, \dots, \mathbf{q}_n$. Then $\mathbf{q}_i^\top\mathbf{S}\mathbf{q}_i$ is the (i,i) entry of $\mathbf{Q}^\top\mathbf{S}\mathbf{Q}$, so the sum over i is $\operatorname{tr}(\mathbf{Q}^\top\mathbf{S}\mathbf{Q}) = \operatorname{tr}\mathbf{S}$ by part (a) applied to $\mathbf{Q}^\top$.

(c) A sum of n numbers equal to $\operatorname{tr}\mathbf{S}$ has a term at least the average $\operatorname{tr}\mathbf{S}/n$, since otherwise the sum would be $< \operatorname{tr}\mathbf{S}$. For Example (Four points, done exactly), $\operatorname{tr}\mathbf{S} = 5$ and the bound is $5/2$; the variances in a frame $(\mathbf{q}_1, \mathbf{q}_2)$ are $\mathbf{q}_1^\top\mathbf{S}\mathbf{q}_1$ and $\mathbf{q}_2^\top\mathbf{S}\mathbf{q}_2$, which sum to 5, so both equal $5/2$ exactly when $\mathbf{q}_1^\top\mathbf{S}\mathbf{q}_1 = 5/2$. Writing $\mathbf{q}_1 = a\mathbf{u}_1 + b\mathbf{u}_2$ with $a^2 + b^2 = 1$ and using $\mathbf{S}\mathbf{u}_1 = 4\mathbf{u}_1$, $\mathbf{S}\mathbf{u}_2 = \mathbf{u}_2$, this reads $4a^2 + b^2 = 5/2$, and subtracting $a^2 + b^2 = 1$ gives $3a^2 = 3/2$, that is $a^2 = b^2 = 1/2$. So the bound is attained exactly by the frames whose vectors split their weight

> equally between $\mathbf{u}_1$ and $\mathbf{u}_2$ — for instance the standard frame $(\mathbf{e}_1, \mathbf{e}_2)$, since $\mathbf{e}_1 = \frac{1}{\sqrt{2}}(\mathbf{u}_1 + \mathbf{u}_2)$; its two variances are indeed $5/2$ each. The extreme case of the spread is visible only in the principal frame; an arbitrary frame hides it.

23.11 Graph Laplacians

Chapter 2 built the incidence matrix of a network, used it to solve flow problems, and then set one object aside with a promise: the matrix $\mathbf{N}\mathbf{N}^\top$, the graph Laplacian, "returns in Chapter 23". Chapter 6 left a second debt at the same address. Its exercise Exercise (C1: Counting spanning trees) computed, for one four-vertex network, that $\det Ł_0$ equals the number of spanning trees, and named the general statement the matrix-tree theorem, leaving a proof "which Chapter 23 completes". This section pays both debts. It also does something the two earlier chapters could not: with the spectral theory of Chapters 11 and 16 in hand, we can read the eigenvalues of Ł and find the shape of the graph in them.

Throughout, a **graph** means what Chapter 2 §07 called a network with its orientation forgotten: a finite set of vertices $1, \dots, m$ and a finite set of edges $1, \dots, k$, each edge joining two **distinct** vertices. Two edges may join the same pair. An **orientation** chooses, for each edge e, a tail and a head, and turns the graph back into one of Chapter 2's networks with an incidence matrix $\mathbf{N} \in M_{m\times k}(\mathbb{R})$ (Definition 2.7.1).

23.11.1 The Laplacian of a graph

The matrix $\mathbf{N}\mathbf{N}^\top$ has already appeared three times without being studied: named and postponed in the closing sentence of Chapter 2 §07's flow-network subsection; implicitly in Exercise (C3: Networks in several pieces), where the kernel of $\mathbf{N}^\top$ — which, as we shall see, is the kernel of $\mathbf{N}\mathbf{N}^\top$ — turned out to be spanned by the indicator vectors of the components; and in Exercise (C1: Counting spanning trees), where its determinant counted something combinatorial. A product that keeps coming back deserves a name.

The Laplacian of a graph is the matrix that turns a labeling of the vertices into the total squared disagreement across the edges.

Definition 23.11.1 — Graph Laplacian

Let G be a graph with vertices $1, \dots, m$ and $k \geq 1$ edges, and fix **any** orientation of G, with incidence matrix $\mathbf{N} \in M_{m\times k}(\mathbb{R})$. The **Laplacian** of G is

$$Ł \coloneqq \mathbf{N}\mathbf{N}^\top \in M_m(\mathbb{R}).$$

In words: the (u, v)-entry of Ł is the dot product of row u and row v of $\mathbf{N}$, that is, the sum over all edges of the product of the two incidence entries. The definition names an orientation, and the first thing to check is that the orientation leaves no trace.

Write $\deg(v)$ for the number of edges meeting the vertex v, and a_{uv} for the number of edges joining u to v when $u \neq v$, with $a_{vv} = 0$. Let $\mathbf{D} = \operatorname{diag}(\deg(1), \dots, \deg(m))$ be the **degree matrix** and $\mathbf{A} = (a_{uv})$ the **adjacency matrix**. Neither mentions an orientation.

Proposition 23.11.1 — First Properties of the Laplacian

Let G be a graph on m vertices with $k \geq 1$ edges and Laplacian Ł. Then:

(a) $Ł = \mathbf{D} - \mathbf{A}$; in particular Ł is symmetric and does **not** depend on the orientation chosen in Definition 23.11.1.

(b) For every $\mathbf{x} \in \mathbb{R}^m$,

$$\mathbf{x}^\top Ł \mathbf{x} = \sum_{e=1}^{k} \left(x_{u_e} - x_{v_e}\right)^2,$$

where u_e and v_e are the two ends of the edge e. Consequently $Ł \succeq 0$.

(c) $Ł\mathbf{1} = \mathbf{0}$, where $\mathbf{1} = (1, \ldots, 1) \in \mathbb{R}^m$.

Idea. Everything is one line of $\mathbf{N}$. Part (a) reads the product $\mathbf{N}\mathbf{N}^\top$ entry by entry, using that a column of $\mathbf{N}$ has exactly one 1 and one -1. Part (b) is the observation that $\mathbf{x}^\top \mathbf{N}\mathbf{N}^\top \mathbf{x}$ is the squared length of $\mathbf{N}^\top \mathbf{x}$, and Chapter 2 already identified $\mathbf{N}^\top \mathbf{x}$ as the vector of differences across the edges. Part (c) is (b) applied to a constant vector, or the fact that each column of $\mathbf{N}$ sums to zero.

Proof.

(a) By Theorem 0.9.2, $(\mathbf{N}\mathbf{N}^\top)_{uv} = \sum_e \mathbf{N}_{ue}\mathbf{N}_{ve}$. If $u = v$, then $\mathbf{N}_{ue}^2$ is 1 when e meets u and 0 otherwise (Definition 2.7.1), so the sum is $\deg(u)$. If $u \neq v$, then $\mathbf{N}_{ue}\mathbf{N}_{ve} \neq 0$ only for an edge e with one end u and the other v, and such an edge contributes $1 \cdot (-1) = -1$ whichever way it is oriented; so the sum is $-a_{uv}$. Hence $Ł = \mathbf{D} - \mathbf{A}$. Both $\mathbf{D}$ and $\mathbf{A}$ are determined by G alone, and $\mathbf{A}$ is symmetric because $a_{uv} = a_{vu}$, so $Ł^\top = Ł$.

(b) As in the proof of Proposition 2.7.4, entry e of $\mathbf{N}^\top \mathbf{x}$ is $x_{\mathrm{tail}(e)} - x_{\mathrm{head}(e)}$, which is $\pm(x_{u_e} - x_{v_e})$. Therefore

$$\mathbf{x}^\top Ł \mathbf{x} = \mathbf{x}^\top \mathbf{N}\mathbf{N}^\top \mathbf{x} = (\mathbf{N}^\top \mathbf{x})^\top (\mathbf{N}^\top \mathbf{x}) = \|\mathbf{N}^\top \mathbf{x}\|^2,$$

and expanding the squared length coordinate by coordinate gives the stated sum, the signs disappearing because each term is squared. For the standard real inner product, $\langle Ł\mathbf{x}, \mathbf{x}\rangle = \mathbf{x}^\top Ł \mathbf{x}$, which is a sum of squares of real numbers and hence ≥ 0; and Ł is symmetric by (a). So $Ł \succeq 0$ by Definition 12.1.1.

(c) Each column of $\mathbf{N}$ has exactly one 1 and one -1, so $\mathbf{N}^\top \mathbf{1} = \mathbf{0}$, and $Ł\mathbf{1} = \mathbf{N}(\mathbf{N}^\top \mathbf{1}) = \mathbf{0}$.

■

Part (b) is the whole reason the Laplacian is useful. A vector $\mathbf{x} \in \mathbb{R}^m$ is a **labeling** of the vertices by numbers, and $\mathbf{x}^\top Ł \mathbf{x}$ measures how badly the labeling disagrees across the edges: it is zero exactly when the labeling is locally constant, and large when neighbors receive very different numbers. Every statement in this section is a consequence of that one reading.

Example. (A Laplacian computed twice)

Let G be the four-vertex graph of Exercise (C1: Counting spanning trees): vertices

$1, 2, 3, 4$ and edges $e_1 = \{1, 2\}$, $e_2 = \{2, 3\}$, $e_3 = \{3, 4\}$, $e_4 = \{4, 1\}$, $e_5 = \{1, 3\}$. Compute Ł from $\mathbf{D} - \mathbf{A}$ and from $\mathbf{N}\mathbf{N}^\top$, and check them against each other.

Solution. The degrees are $\deg(1) = 3$, $\deg(2) = 2$, $\deg(3) = 3$, $\deg(4) = 2$, and every pair of vertices is joined by at most one edge, the missing pair being $\{2, 4\}$. Hence

$$\mathbf{D} - \mathbf{A} = \begin{pmatrix} 3 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix} - \begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 \\ 1 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{pmatrix} = \begin{pmatrix} 3 & -1 & -1 & -1 \\ -1 & 2 & -1 & 0 \\ -1 & -1 & 3 & -1 \\ -1 & 0 & -1 & 2 \end{pmatrix}.$$

Orienting the edges as $1 \to 2$, $2 \to 3$, $3 \to 4$, $4 \to 1$, $1 \to 3$ gives the incidence matrix of Exercise (C1: Counting spanning trees),

$$\mathbf{N} = \begin{pmatrix} 1 & 0 & 0 & -1 & 1 \\ -1 & 1 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 & -1 \\ 0 & 0 & -1 & 1 & 0 \end{pmatrix},$$

whose row 1 has squared length $1 + 1 + 1 = 3$, and whose rows 1 and 2 have dot product $1 \cdot (-1) = -1$. Continuing entry by entry reproduces the matrix above, so the two computations agree. Reversing the orientation of the edge $1 \to 2$ changes the first two rows of $\mathbf{N}$ in their first entry only, from 1 and -1 to -1 and 1; the diagonal entries are unchanged because they are sums of squares, and the $(1, 2)$-entry is still $(-1) \cdot 1 = -1$.

Warning. **Take the oriented incidence matrix, not the unoriented one.** If one replaces the -1 in Definition 2.7.1 by $+1$, obtaining the matrix $\mathbf{M}$ with a 1 at both ends of each edge, then $\mathbf{M}\mathbf{M}^\top = \mathbf{D} + \mathbf{A}$, not $\mathbf{D} - \mathbf{A}$. That matrix is also symmetric and positive semidefinite, but it is a different matrix with a different kernel: for the triangle, $\mathbf{D} - \mathbf{A}$ is singular while $\mathbf{D} + \mathbf{A}$ has determinant 4. The signs are what make Proposition 23.11.1 (b) a sum of **differences**, and the sign convention returns in Lemma 23.11.6, where it is load-bearing again.

Quick check. The graph of Example (A Laplacian computed twice) has the labeling $\mathbf{x} = (1, 1, 0, 0)$. Compute $\mathbf{x}^\top Ł \mathbf{x}$ from the edge formula, and say which edges contribute.

Solution. By Proposition 23.11.1 (b), each edge contributes the square of the difference of the labels at its ends. The edges $\{1, 2\}$ and $\{3, 4\}$ join equal labels and contribute 0; the edges $\{2, 3\}$, $\{4, 1\}$ and $\{1, 3\}$ each join a 1 to a 0 and contribute 1. So $\mathbf{x}^\top Ł \mathbf{x} = 3$, the number of edges crossing between $\{1, 2\}$ and $\{3, 4\}$. Directly: $Ł\mathbf{x} = (3 - 1, -1 + 2, -1 - 1, -1 + 0) = (2, 1, -2, -1)$ and $\mathbf{x}^\top Ł \mathbf{x} = 2 + 1 = 3$.

23.11.2 The kernel counts the components

Chapter 2's Exercise (C3: Networks in several pieces) computed $\mathrm{nul}(\mathbf{N}^\top)$ for a network in several pieces. That was an exercise, so we prove what we need here, in the form the spectral theory will use. Recall from Exercise (C3: Networks in several pieces) the notion we need: two vertices are **linked** if some sequence of vertices joins them with consecutive vertices sharing an edge, and the equivalence classes of this relation are the **components** of G. That "linked" is an equivalence relation (Definition 0.5.2) takes one line: it is reflexive by the sequence of length

zero, symmetric because a sequence reversed is again one, and transitive because two sequences may be concatenated. So the components partition the vertices (Theorem 0.5.2), which is what Step 3 below uses.

Theorem 23.11.2 — The Kernel of the Laplacian

Let G be a graph on m vertices with $k \geq 1$ edges, with components $C_1, \dots, C_c$, and let $\mathbf{1}_{C_r} \in \mathbb{R}^m$ be the vector with entry 1 at the vertices of C_r and 0 elsewhere. Then

$$\operatorname{nul}(Ł) = \operatorname{span}\big(\mathbf{1}_{C_1}, \dots, \mathbf{1}_{C_c}\big),$$

this list is a basis, and the eigenvalue 0 of Ł has multiplicity exactly c. In particular Ł is singular, and $\operatorname{nul}(Ł) = \operatorname{span}(\mathbf{1})$ exactly when G is connected.

Idea. For a positive semidefinite matrix, lying in the kernel and making the quadratic form vanish are the same condition, and Proposition 23.11.1 (b) turns the second one into a statement with no linear algebra in it at all: the labeling is constant across every edge. Constant across every edge propagates along chains of edges, so it means constant on each component, which is exactly what the indicator vectors describe.

Proof. **Step 1: $\mathbf{x} \in \operatorname{nul}(Ł)$ if and only if $\mathbf{x}^\top Ł\mathbf{x} = 0$.** If $Ł\mathbf{x} = \mathbf{0}$, then $\mathbf{x}^\top Ł\mathbf{x} = 0$. Conversely, if $\mathbf{x}^\top Ł\mathbf{x} = 0$, then $\|\mathbf{N}^\top\mathbf{x}\|^2 = 0$ by the display in the proof of Proposition 23.11.1 (b), so $\mathbf{N}^\top\mathbf{x} = \mathbf{0}$ and $Ł\mathbf{x} = \mathbf{N}(\mathbf{N}^\top\mathbf{x}) = \mathbf{0}$.

Step 2: $\mathbf{x}^\top Ł\mathbf{x} = 0$ if and only if $\mathbf{x}$ is constant on each component. By Proposition 23.11.1 (b), $\mathbf{x}^\top Ł\mathbf{x}$ is a sum of squares of real numbers, so it vanishes if and only if every term does, that is, if and only if $x_u = x_v$ for every edge with ends u and v. Suppose this holds and let u, w lie in the same component. By the definition of linked there is a sequence $u = w_0, w_1, \dots, w_t = w$ with consecutive vertices joined by an edge, so $x_u = x_{w_1} = \cdots = x_w$. Hence $\mathbf{x}$ is constant on each component. Conversely, if $\mathbf{x}$ is constant on each component, then the two ends of any edge lie in the same component and carry the same label, so every term vanishes.

Step 3: the indicators are a basis. By Steps 1 and 2, $\mathbf{x} \in \operatorname{nul}(Ł)$ if and only if $\mathbf{x} = \sum_{r=1}^{c} \lambda_r \mathbf{1}_{C_r}$, where λ_r is the common value of $\mathbf{x}$ on C_r; so the list spans $\operatorname{nul}(Ł)$. It is linearly independent: if $\sum_r \lambda_r \mathbf{1}_{C_r} = \mathbf{0}$, then reading the entry at any vertex of C_r gives $\lambda_r = 0$, since the components are disjoint and only the r-th vector is non-zero there. Hence $\dim \operatorname{nul}(Ł) = c$.

Step 4: multiplicity. Ł is symmetric by Proposition 23.11.1 (a), so by Corollary 11.5.2 it is orthogonally diagonalizable, and the number of times 0 occurs in its eigenvalue list is the dimension of its 0-eigenspace, which is $\operatorname{nul}(Ł)$. That dimension is $c \geq 1$, so Ł is singular. Finally, G is connected exactly when $c = 1$, and then C_1 is the whole vertex set and $\mathbf{1}_{C_1} = \mathbf{1}$.

■

This is the first of the two theorems that the Laplacian is for. Notice how little it costs: the entire combinatorial content sits in Step 2, and the only property of Ł used is that its quadratic form is a sum of squares over the edges.

23.11.3 The Fiedler value

Theorem 23.11.2 says that 0 is always an eigenvalue and that its multiplicity detects whether the graph falls apart. The natural next question is quantitative: if the graph is connected, *how* connected is it? The eigenvalue just above 0 answers this, and the reason is Proposition 23.11.1 (b) again.

Because $Ł \succeq 0$, all its eigenvalues are ≥ 0 (Theorem 12.1.4 (b)), and it is convenient here to list them **increasingly**, against the book's usual convention. Write

$$\mu_1(Ł) \leq \mu_2(Ł) \leq \cdots \leq \mu_m(Ł)$$

for the eigenvalues of Ł with multiplicity in increasing order, so that $\mu_j(Ł) = \lambda_{m+1-j}(Ł)$ in the decreasing notation of Chapter 16. By Theorem 23.11.2, $\mu_1(Ł) = 0$.

Definition 23.11.2 — Fiedler value

Let G be a graph on $m \geq 2$ vertices with at least one edge. The **Fiedler value**, or **algebraic connectivity**, of G is the **second smallest** eigenvalue $\mu_2(Ł)$ of its Laplacian, counted with multiplicity.

For the complete graph K_m, in which every pair of distinct vertices is joined by one edge, Proposition 23.11.1 (a) gives $Ł = m\mathbf{I} - \mathbf{J}$, where $\mathbf{J}$ is the all-ones matrix. Every row of $\mathbf{J}$ equals $\mathbf{1}^\top$, so $\operatorname{rank}\mathbf{J} = 1$ and 0 is an eigenvalue of $\mathbf{J}$ of multiplicity $m-1$ by Theorem 2.5.7; and $\mathbf{J1} = m\mathbf{1}$ supplies the last eigenvalue m. Hence Ł has eigenvalues 0 once and m with multiplicity $m-1$, and the Fiedler value of K_m is m. For a graph in two or more pieces it is 0, by Theorem 23.11.2. A single edge on two vertices has Laplacian $\begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}$ and Fiedler value 2. The degenerate case $m = 1$ is excluded because there is no second eigenvalue.

Proposition 23.11.3 — Positive Fiedler Value Means Connected

Let G be a graph on $m \geq 2$ vertices with at least one edge. Then $\mu_2(Ł) > 0$ if and only if G is connected.

Proof. The eigenvalues of Ł are ≥ 0, so $\mu_2(Ł) = 0$ if and only if the eigenvalue 0 occurs at least twice in the list, that is, if and only if its multiplicity c is at least 2 (Theorem 23.11.2). That happens exactly when G has two or more components, that is, exactly when G is not connected. ∎

The number $\mu_2(Ł)$ is therefore a graded version of connectedness, and the grading has a meaning that can be read off directly.

Proposition 23.11.4 — The Fiedler Value as a Minimum

Let G be a graph on $m \geq 2$ vertices with at least one edge. Then

$$\mu_2(Ł) = \min\left\{ \frac{\mathbf{x}^\top Ł \mathbf{x}}{\mathbf{x}^\top \mathbf{x}} \;:\; \mathbf{x} \in \mathbb{R}^m,\ \mathbf{x} \neq \mathbf{0},\ \mathbf{x}^\top \mathbf{1} = 0 \right\},$$

and the minimum is attained at an eigenvector for $\mu_2(Ł)$.

Idea. The quantity being minimized is the Rayleigh quotient $R_Ł$ of Chapter 16. Over all of $\mathbb{R}^m$ its minimum is $\mu_1(Ł) = 0$, attained at $\mathbf{1}$, so the constraint $\mathbf{x} \perp \mathbf{1}$ exactly removes the direction that achieves 0. What makes this work is that an orthonormal eigenbasis can be chosen with $\mathbf{1}/\sqrt{m}$ as its first member; after that the computation is the weighted-average argument of Chapter 16, run once.

Proof. Since Ł is symmetric, Corollary 11.5.2 supplies an orthonormal basis $(\mathbf{q}_1, \ldots, \mathbf{q}_m)$ of $\mathbb{R}^m$ with $Ł\mathbf{q}_j = \mu_j(Ł)\mathbf{q}_j$, the eigenvalues in the prescribed increasing order; moreover the basis may be chosen so that $\mathbf{q}_1 = \mathbf{1}/\sqrt{m}$. Indeed, let $E_0 = \mathrm{nul}(Ł)$, of dimension $c \geq 1$ by Theorem 23.11.2, and note $\mathbf{1} \in E_0$ and $\mathbf{1} \neq \mathbf{0}$. Applying Gram–Schmidt (Theorem 10.2.2) to a basis of E_0 beginning with $\mathbf{1}$ gives an orthonormal basis of E_0 whose first member is $\mathbf{1}/\sqrt{m}$; joining it to orthonormal bases of the other eigenspaces gives the required basis, because $\mu_1(Ł) = \cdots = \mu_c(Ł) = 0$ are the eigenvalues attached to E_0.

Now let $\mathbf{x} \neq \mathbf{0}$ with $\mathbf{x}^\top \mathbf{1} = 0$, and write $c_j = \langle \mathbf{x}, \mathbf{q}_j \rangle$, so that $\mathbf{x} = \sum_j c_j \mathbf{q}_j$ by Theorem 10.2.1 (a). The constraint says $c_1 = \langle \mathbf{x}, \mathbf{1} \rangle / \sqrt{m} = 0$. Hence, by Theorem 10.2.1 (b), (c),

$$\frac{\mathbf{x}^\top Ł \mathbf{x}}{\mathbf{x}^\top \mathbf{x}} = \frac{\sum_{j \geq 2} \mu_j(Ł)\, c_j^2}{\sum_{j \geq 2} c_j^2} \;\geq\; \mu_2(Ł),$$

a weighted average of $\mu_2(Ł), \ldots, \mu_m(Ł)$ with non-negative weights, not all zero, being at least the smallest of them. Taking $\mathbf{x} = \mathbf{q}_2$, which satisfies $\mathbf{q}_2 \perp \mathbf{q}_1 = \mathbf{1}/\sqrt{m}$ and is non-zero, gives the value $\mu_2(Ł)$. So the set has minimum $\mu_2(Ł)$, attained at $\mathbf{q}_2$.

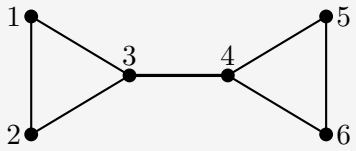
■

Remark. This is the $k = m - 1$ case of the max–min half of Theorem 16.2.3, read in the increasing indexing: there $\lambda_{m-1}(Ł) = \mu_2(Ł)$ is the largest value that any $(m-1)$-dimensional subspace can guarantee for $R_Ł$, and the proposition says that the particular subspace $\mathbf{1}^\perp$ already guarantees it.

A vector achieving the minimum is called a **Fiedler vector**. It must have entries of both signs, since it is orthogonal to $\mathbf{1}$, and Proposition 23.11.1 (b) says it is a labeling that keeps neighbors as close together as it can while being spread out overall. Splitting the vertices by the sign of a Fiedler vector is therefore a reasonable guess at a partition that cuts few edges.

Example. (Two triangles and a bridge)

Let G have vertices $1, \ldots, 6$ and edges $\{1,2\}$, $\{1,3\}$, $\{2,3\}$, $\{3,4\}$, $\{4,5\}$, $\{4,6\}$, $\{5,6\}$: two triangles joined by a single edge.



Find the Fiedler value and a Fiedler vector, and read off the partition.

Solution. The degrees are $2, 2, 3, 3, 2, 2$, so

$$Ł = \begin{pmatrix} 2 & -1 & -1 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 & 0 \\ -1 & -1 & 3 & -1 & 0 & 0 \\ 0 & 0 & -1 & 3 & -1 & -1 \\ 0 & 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & -1 & -1 & 2 \end{pmatrix}.$$

Rather than expand a 6×6 characteristic polynomial, guess the shape of the answer from the symmetry: the graph is carried to itself by the reflection $1 \leftrightarrow 6$, $2 \leftrightarrow 5$, $3 \leftrightarrow 4$, and by the swap $1 \leftrightarrow 2$. Look for an eigenvector reversed by the reflection and fixed by the swap, that is, of the form $\mathbf{x} = (1, 1, b, -b, -1, -1)$. Rows 1 and 3 of $Ł\mathbf{x} = \mu\mathbf{x}$ read

$$1 - b = \mu, \qquad -2 + 4b = \mu b,$$

the other four rows repeating these by symmetry. Substituting $\mu = 1 - b$ into the second gives $-2 + 4b = b - b^2$, that is $b^2 + 3b - 2 = 0$, whose positive root is $b = (\sqrt{17} - 3)/2$. Then

$$\mu = 1 - b = \frac{5 - \sqrt{17}}{2} \approx 0.4384.$$

The vector $\mathbf{x}$ satisfies $\mathbf{x}^\top \mathbf{1} = 2 + b - b - 2 = 0$, so by Proposition 23.11.4 its Rayleigh quotient, which is μ, is at least $\mu_2(Ł)$; and $\mu > 0$, so $\mu \neq \mu_1(Ł) = 0$. To see that μ really is the second smallest, note that $\mathbf{x}$ and $\mathbf{1}$ are eigenvectors for the distinct eigenvalues μ and 0, and check that the remaining four eigenvalues are larger: the vectors $(1, -1, 0, 0, 0, 0)$, $(0, 0, 0, 0, 1, -1)$ and $(1, 1, -2, -2, 1, 1)$ are eigenvectors for the eigenvalue 3, as one verifies row by row, and they are visibly independent, so together with $\mathbf{1}$ and $\mathbf{x}$ they account for five of the six. For the third of them, for instance, row 3 of Ł gives $-1 - 1 - 6 + 2 = -6 = 3 \cdot (-2)$ and row 1 gives $2 - 1 + 2 = 3 = 3 \cdot 1$. The trace of Ł is $2 + 2 + 3 + 3 + 2 + 2 = 14$, so the sixth eigenvalue is $14 - (0 + \mu + 3 + 3 + 3) = 5 - \mu = (5 + \sqrt{17})/2$, also larger than μ. Hence

$$\mu_2(Ł) = \frac{5 - \sqrt{17}}{2}, \qquad \mathbf{x} = \Big(1,\ 1,\ \tfrac{\sqrt{17}-3}{2},\ -\tfrac{\sqrt{17}-3}{2},\ -1,\ -1\Big)$$

is a Fiedler vector, and the signs of its entries split the vertices as $\{1, 2, 3\} \mid \{4, 5, 6\}$: exactly the two triangles, cut along the bridge.

Compare the Fiedler value $0.4384\ldots$ of this graph with the value 6 for K_6. Small means "nearly disconnected", and the bridge is what makes it small. One general fact in that direction is immediate from Chapter 16.

Proposition 23.11.5 — Adding an Edge Raises No Eigenvalue

Let G be a graph on m vertices with at least one edge, and let G' be G with one extra edge joining $u \neq v$. Then $Ł' = Ł + \mathbf{w}\mathbf{w}^\top$ with $\mathbf{w} = \mathbf{e}_u - \mathbf{e}_v$, and

$$\mu_j(Ł') \;\geq\; \mu_j(Ł) \qquad (j = 1, \dots, m).$$

In particular the Fiedler value does not decrease when an edge is added.

Proof. The extra edge adds 1 to $\deg(u)$ and to $\deg(v)$ and 1 to a_{uv} and a_{vu}, so by Proposition 23.11.1 (a), $Ł' - Ł$ has entries 1 at (u,u) and (v,v), -1 at (u,v) and (v,u), and 0 elsewhere; that matrix is $\mathbf{w}\mathbf{w}^\top$. Now $\mathbf{w}\mathbf{w}^\top$ is symmetric, and $\mathbf{x}^\top \mathbf{w}\mathbf{w}^\top \mathbf{x} = (\mathbf{w}^\top \mathbf{x})^2 \geq 0$ for every $\mathbf{x}$, so $\mathbf{w}\mathbf{w}^\top \succeq 0$ and $Ł' \succeq Ł$ in the Loewner order (Definition 12.5.1). By Corollary 16.2.4, $\lambda_i(Ł') \geq \lambda_i(Ł)$ for every i, and rewriting the decreasing index $i = m + 1 - j$ as the increasing index j gives the claim. ∎

23.11.4 Counting spanning trees

Now the second theorem, and the one Chapter 6 promised. Two more words are needed, and both are about the graph alone.

A **cycle** is a set of edges $\{f_1, \dots, f_t\}$ with $t \geq 2$ that can be listed together with distinct vertices $w_0, w_1, \dots, w_{t-1}$ so that, setting $w_t = w_0$, the edge f_i joins w_{i-1} to w_i for each i. Two edges joining the same pair of vertices form a cycle with $t = 2$. A **spanning tree** of G is a set T of edges such that the graph with all m vertices and only the edges of T is connected and contains no cycle. In Exercise (C1: Counting spanning trees) the phrase was "a set of 3 edges that connects all four vertices", and the proposition below reconciles the two descriptions.

The bridge from graphs to determinants is the following lemma. It is where such proofs usually go wrong, so read the third part carefully: it is a statement about $(m-1) \times (m-1)$ submatrices of $\mathbf{N}$ with one row deleted, not about arbitrary square submatrices, and the "exactly when" is an equivalence in both directions.

Lemma 23.11.6 — Unimodularity of Incidence Minors

Let $\mathbf{N} \in M_{m \times k}(\mathbb{R})$ be the incidence matrix of an oriented graph G with m vertices and $k \geq 1$ edges. Write $\mathbf{n}_e \in \mathbb{R}^m$ for the column of $\mathbf{N}$ belonging to the edge e.

(a) Every square submatrix of $\mathbf{N}$ has determinant 0, 1 or -1.

(b) For a set S of edges, the list $(\mathbf{n}_e)_{e \in S}$ is linearly independent if and only if S contains no cycle.

(c) Fix a vertex r and put $I = [m] \setminus \{r\}$. For a set S of **exactly** $m - 1$ edges, S is a spanning tree of G if and only if it contains no cycle, and

$$\det \mathbf{N}_{I,S} = \begin{cases} \pm 1 & \text{if } S \text{ is a spanning tree of } G, \\ 0 & \text{otherwise.} \end{cases}$$

Idea. ① For (a), induct on the size of the square submatrix and look at its columns. A column of $\mathbf{N}$ restricted to a subset of the rows keeps at most the one 1 and the one -1. If some column of the submatrix is zero, the determinant is 0; if some column has a single non-zero entry, expand along it and the size drops; and if **every** column has both, then the rows of the submatrix add up to zero, so they are dependent. ② For (b), a cycle gives an explicit dependence — walk around it and the telescoping sum collapses. Conversely a dependence, restricted to the edges with non-zero coefficient, forces every vertex to meet either none or at least two of them, and a finite graph with that property contains a cycle. ③ Part (c) combines the two, once one knows that deleting the row r costs no rank, which it does not, because the rows of $\mathbf{N}$ already sum to zero.

Proof. **(a)** We induct on t, the common number of rows and columns of the square submatrix $\mathbf{B} = \mathbf{N}_{I',S'}$. For $t = 1$, $\mathbf{B}$ is a single entry of $\mathbf{N}$, which is 0, 1 or -1 by Definition 2.7.1. Let $t \geq 2$ and assume the claim for $t-1$. Each column of $\mathbf{N}$ has exactly one 1 and one -1, so each column of $\mathbf{B}$ has at most one 1 and at most one -1 and no other non-zero entries. Three cases.

Case 1: some column of $\mathbf{B}$ *is zero.* Then $\det \mathbf{B} = 0$ by Theorem 6.2.1.

Case 2: some column of $\mathbf{B}$ *has exactly one non-zero entry* $\varepsilon = \pm 1$*, in row* p *say.* Expanding along that column (Theorem 6.6.1) gives $\det \mathbf{B} = \pm\varepsilon \det \mathbf{B}'$, where $\mathbf{B}'$ is $\mathbf{B}$ with that row and column deleted. But $\mathbf{B}'$ is again a square submatrix of $\mathbf{N}$, of size $t-1$, so $\det \mathbf{B}' \in \{0, 1, -1\}$ by the induction hypothesis, and hence so is $\det \mathbf{B}$.

Case 3: every column of $\mathbf{B}$ *has both a* 1 *and a* -1. Then every column sums to 0, so the sum of all t rows of $\mathbf{B}$ is the zero row; the rows are linearly dependent, and $\det \mathbf{B} = 0$ by Theorem 6.2.1 and Theorem 6.4.5.

These three cases are exhaustive, which completes the induction.

(b) ($\Leftarrow$) We prove the contrapositive: suppose $\sum_{e \in S} a_e \mathbf{n}_e = \mathbf{0}$ with some $a_e \neq 0$, and let $S' = \{e \in S : a_e \neq 0\}$, a non-empty subset of S. Fix a vertex v. Entry v of the sum is $\sum_{e \in S'} a_e \mathbf{N}_{ve}$, and $\mathbf{N}_{ve} = \pm 1$ exactly for the edges of S' meeting v, and 0 otherwise. If exactly one edge $e_0 \in S'$ met v, that entry would be $\pm a_{e_0} \neq 0$, contradicting the sum being $\mathbf{0}$. So **every vertex meets either no edge of** S' **or at least two**.

Now build a walk. Pick any $f_1 \in S'$, with ends w_0 and w_1. Having reached w_i along f_i, the vertex w_i meets at least two edges of S', so we may choose $f_{i+1} \in S'$ with $f_{i+1} \neq f_i$ meeting w_i, and let w_{i+1} be its other end. Since there are only m vertices, some vertex repeats; let i be the smallest index with $w_i \in \{w_0, \dots, w_{i-1}\}$, and let $j < i$ be the index with $w_j = w_i$. Then $w_j, w_{j+1}, \dots, w_{i-1}$ are distinct, by the minimality of i, and $f_{j+1}, \dots, f_i$ join them in a closed chain. Put $t = i - j$. First, $t \geq 2$: $t = 1$ would mean that f_{j+1} joins w_j to itself, and an edge joins two **distinct** vertices. Second, the t edges are distinct: for $t = 2$ that is the construction, $f_{j+2} \neq f_{j+1}$; and for $t \geq 3$ the pairs $\{w_{a-1}, w_a\}$ for $j+1 \leq a \leq i$ are pairwise different pairs of the distinct vertices $w_j, \dots, w_{i-1}$, so the edges joining them differ. So $\{f_{j+1}, \dots, f_i\}$ is a cycle, and it lies in $S' \subseteq S$.

($\Rightarrow$) Again by contraposition. Let $\{f_1, \dots, f_t\} \subseteq S$ be a cycle with vertices $w_0, \dots, w_{t-1}$ and $w_t = w_0$ as in the definition. For each i set $\varepsilon_i = 1$ if f_i is oriented from w_{i-1} to w_i, and $\varepsilon_i = -1$ otherwise. By Definition 2.7.1 the column of an edge oriented from a to b

is $\mathbf{e}_a - \mathbf{e}_b$, so in either case $\varepsilon_i \mathbf{n}_{f_i} = \mathbf{e}_{w_{i-1}} - \mathbf{e}_{w_i}$. Summing telescopes:

$$\sum_{i=1}^{t} \varepsilon_i \mathbf{n}_{f_i} = \mathbf{e}_{w_0} - \mathbf{e}_{w_t} = \mathbf{0},$$

a dependence with all coefficients ± 1, so the list $(\mathbf{n}_e)_{e \in S}$ is dependent.

(c) Write $\mathbf{N}_S = \mathbf{N}_{[m],S} \in M_{m \times (m-1)}(\mathbb{R})$ for the full columns and $\mathbf{N}_{I,S} \in M_{m-1}(\mathbb{R})$ for the same columns with row r deleted. Every column of $\mathbf{N}$ sums to 0, so row r of $\mathbf{N}_S$ is minus the sum of the other rows; deleting it therefore does not change the row space, and by Theorem 2.5.5

$$\operatorname{rank} \mathbf{N}_{I,S} = \operatorname{rank} \mathbf{N}_S.$$

Hence $\det \mathbf{N}_{I,S} \neq 0$ if and only if $\operatorname{rank} \mathbf{N}_S = m - 1$ (Theorem 2.4.4 and Theorem 6.5.2), that is, if and only if the $m - 1$ columns $(\mathbf{n}_e)_{e \in S}$ are linearly independent, which by (b) holds if and only if S contains no cycle. When it does not vanish, $\det \mathbf{N}_{I,S} = \pm 1$ by (a).

It remains to check the equivalence in the statement: for a set S of $m - 1$ edges, "no cycle" and "spanning tree" agree. A spanning tree contains no cycle by definition. Conversely, suppose S has $m - 1$ edges and no cycle; we must show that the graph H with all m vertices and the edges of S is connected. By (b) the columns of $\mathbf{N}_S$ are independent, so $\operatorname{rank} \mathbf{N}_S = m - 1$ and $\dim \operatorname{col}(\mathbf{N}_S) = m - 1$. Each column of $\mathbf{N}_S$ lies in $W = \{\mathbf{z} \in \mathbb{R}^m : z_1 + \cdots + z_m = 0\}$, which has dimension $m - 1$ as computed in the proof of Corollary 2.7.5, so $\operatorname{col}(\mathbf{N}_S) = W$ by Theorem 1.6.8. Suppose H were disconnected, and let C be the vertex set of one of its components, so $\emptyset \neq C \neq [m]$. Every edge of S has both ends in C or both ends outside C, so $\mathbf{1}_C^{\top} \mathbf{n}_e = 0$ for every $e \in S$, and hence $\mathbf{1}_C^{\top} \mathbf{z} = 0$ for every $\mathbf{z} \in \operatorname{col}(\mathbf{N}_S) = W$. But choosing $u \in C$ and $v \notin C$ gives $\mathbf{z} = \mathbf{e}_u - \mathbf{e}_v \in W$ with $\mathbf{1}_C^{\top} \mathbf{z} = 1 \neq 0$, a contradiction. So H is connected, and S is a spanning tree.

■

Remark. Part (a) says that $\mathbf{N}$ is **totally unimodular**, the standard name for a matrix every square submatrix of which has determinant 0, 1 or -1. The orientation is essential: for the triangle with edges $\{1,2\}, \{2,3\}, \{3,1\}$, the unoriented matrix of the warning above is $\left(\begin{smallmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{smallmatrix}\right)$, whose determinant is 2. Case 3 of the proof is exactly where the -1 is spent.

One consequence of the last paragraph of the proof is worth recording separately, since it is what makes the sum in the theorem below a sum over spanning trees rather than over sets of every size.

Proposition 23.11.7 — A Spanning Tree Has $m - 1$ Edges

Let G be a graph on $m \geq 2$ vertices. Every spanning tree of G has exactly $m - 1$ edges. Conversely, if a set S of exactly $m - 1$ edges is such that the graph on all m vertices with edge set S is connected, then S is a spanning tree.

Proof. Let T be a spanning tree and let H be the graph on all m vertices with edge set T. Then H is connected, so $T \neq \emptyset$ (for $m \geq 2$) and Proposition 2.7.4 applied to H gives $\operatorname{rank} \mathbf{N}_T = m - 1$, where $\mathbf{N}_T$ is the incidence matrix of H with some orientation, that is, the columns of $\mathbf{N}$ indexed by T. Also T contains no cycle, so those columns are linearly

independent by Lemma 23.11.6 (b), and therefore $|T| = \operatorname{rank} \mathbf{N}_T = m - 1$.

Conversely, let S have exactly $m-1$ edges and let H be the graph on all m vertices with edge set S, assumed connected. By Proposition 2.7.4 applied to H, $\operatorname{rank} \mathbf{N}_S = m - 1$, where $\mathbf{N}_S$ is the incidence matrix of H, that is, the columns of $\mathbf{N}$ indexed by S; it has $m - 1$ columns, so Theorem 2.5.7 gives $\operatorname{nul}(\mathbf{N}_S) = \{\mathbf{0}\}$; since $\mathbf{N}_S\mathbf{a} = \sum_{e \in S} a_e \mathbf{n}_e$ by Theorem 0.9.3, the columns $(\mathbf{n}_e)_{e \in S}$ are linearly independent. By Lemma 23.11.6 (b), S contains no cycle, and H is connected, so S is a spanning tree. In particular the sets counted here are exactly the "sets of 3 edges that connect all four vertices" of Exercise (C1: Counting spanning trees).

■

Theorem 23.11.8 — Matrix-Tree Theorem

Let G be a graph on $m \geq 2$ vertices with $k \geq 1$ edges and Laplacian Ł. Fix a vertex r, and let $Ł_0 = Ł_{I,I} \in M_{m-1}(\mathbb{R})$ be Ł with the row and the column of r deleted, where $I = [m] \setminus \{r\}$. Then

$$\det Ł_0 = \#\{\text{spanning trees of } G\}.$$

In particular the answer does not depend on which vertex r is deleted, and $\det Ł_0 = 0$ exactly when G is disconnected.

Idea. The determinant of $Ł_0$ is the determinant of a Gram matrix, because $Ł_0 = \mathbf{N}_0\mathbf{N}_0^{\top}$ for the reduced incidence matrix $\mathbf{N}_0$. Corollary 6.7.3 writes such a determinant as a sum of squares of $(m-1) \times (m-1)$ minors, one for each set of $m-1$ edges. Lemma 23.11.6 says that each of those squares is 1 for a spanning tree and 0 for anything else. So the sum counts spanning trees, one apiece. Every step has already been proved; the theorem is the three of them placed in a row.

Proof. Fix an orientation of G, with incidence matrix $\mathbf{N}$, and put $\mathbf{N}_0 = \mathbf{N}_{I,[k]} \in M_{(m-1)\times k}(\mathbb{R})$, the matrix $\mathbf{N}$ with the row of r deleted.

Step 1: $Ł_0 = \mathbf{N}_0\mathbf{N}_0^{\top}$. By Theorem 0.9.2, the (u, v)-entry of $\mathbf{N}\mathbf{N}^{\top}$ is row u of $\mathbf{N}$ dotted with row v of $\mathbf{N}$. Deleting the row and the column of r from $\mathbf{N}\mathbf{N}^{\top}$ therefore leaves exactly the dot products of the rows indexed by I, which is $\mathbf{N}_0\mathbf{N}_0^{\top}$.

Step 2: Cauchy–Binet. Applying Corollary 6.7.3 to $\mathbf{N}_0 \in M_{(m-1)\times k}(\mathbb{R})$,

$$\det Ł_0 = \sum_{\substack{S \subseteq [k] \\ |S| = m-1}} \left(\det(\mathbf{N}_0)_{[m-1],S}\right)^2,$$

one term for each set S of exactly $m-1$ edges. The submatrix $(\mathbf{N}_0)_{[m-1],S}$ keeps all rows of $\mathbf{N}_0$ and the columns S, so it is the submatrix of $\mathbf{N}$ on rows I and columns S, namely $\mathbf{N}_{I,S}$.

Step 3: identify the terms. By Lemma 23.11.6 (c), $\det \mathbf{N}_{I,S} = \pm 1$ when S is a spanning tree and 0 otherwise, so each term of the sum is 1 for a spanning tree and 0 otherwise. By Proposition 23.11.7 every spanning tree has exactly $m-1$ edges, so every spanning tree occurs as one of the sets S, and it occurs once. Hence the sum is the number of spanning trees.

The left-hand side of Step 2 was computed from a particular r, and the right-hand side does not mention r, so the value is the same for every choice. Finally, a disconnected graph has no spanning tree, since a spanning tree is connected on all m vertices, so the sum is empty and $\det Ł_0 = 0$. A connected graph has at least one: by Proposition 2.7.4, $\operatorname{rank} \mathbf{N} = m - 1$, and deleting the row of r does not change the row space, since every column of $\mathbf{N}$ sums to 0, so $\operatorname{rank} \mathbf{N}_0 = m - 1$ by Theorem 2.5.5. As $\mathbf{N}_0$ has $m - 1$ rows, Theorem 6.7.1 (a) gives a non-zero $(m-1) \times (m-1)$ minor of $\mathbf{N}_0$, which uses all its rows and some set S of $m - 1$ columns; that minor is $\det \mathbf{N}_{I,S} \neq 0$, so S is a spanning tree by Lemma 23.11.6 (c). Hence $\det Ł_0 = 0$ exactly when G is disconnected.

■

Example. (The four-vertex graph, counted both ways)

For the graph of Example (A Laplacian computed twice), compute $\det Ł_0$ with $r = 4$, and list the spanning trees.

Solution. Deleting the row and column of vertex 4 from the Laplacian computed in Example (A Laplacian computed twice) leaves the 3×3 matrix whose determinant Exercise (C1: Counting spanning trees) (a) expands along its first row: $\det Ł_0 = 8$.

Now count directly. A spanning tree has $4 - 1 = 3$ edges by Proposition 23.11.7, and there are $\binom{5}{3} = 10$ sets of three edges. By Lemma 23.11.6 (c) such a set fails to be a spanning tree exactly when it contains a cycle, and the only cycles with three or fewer edges are the triangles $\{e_1, e_2, e_5\}$ on vertices $1, 2, 3$ and $\{e_3, e_4, e_5\}$ on vertices $1, 3, 4$, in the edge numbering of Example (A Laplacian computed twice). So $10 - 2 = 8$ of the sets are spanning trees, matching $\det Ł_0 = 8$.

As a check on one term of the sum in the proof, the tree $\{e_1, e_2, e_3\}$ gives, on rows $I = \{1, 2, 3\}$,

$$\mathbf{N}_{I,\{1,2,3\}} = \begin{pmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 0 & -1 & 1 \end{pmatrix},$$

lower triangular with determinant 1 (Theorem 6.4.6). The matching computation for a non-tree, whose minor is 0, is Exercise (C1: Counting spanning trees) (d).

Warning. **Delete one row and the matching column, and no more.** The Laplacian itself is always singular by Theorem 23.11.2, so $\det Ł = 0$ says nothing. Deleting **two** vertices does not count anything either: for the four-cycle with edges $\{1,2\}, \{2,3\}, \{3,4\}, \{4,1\}$, striking out the rows and columns of 3 and 4 leaves $\left(\begin{smallmatrix} 2 & -1 \\ -1 & 2 \end{smallmatrix}\right)$, of determinant 3, while the graph has 4 spanning trees. And the proof needs the deleted row and the deleted column to belong to the **same** vertex, since Step 1 produces a Gram matrix $\mathbf{N}_0 \mathbf{N}_0^\top$ only then; that is a constraint on this route, and nothing above claims that a mismatched pair of deletions counts nothing. Note also that the theorem counts **sets of edges**, so parallel edges count as different trees: two vertices joined by three parallel edges have $Ł = \begin{pmatrix} 3 & -3 \\ -3 & 3 \end{pmatrix}$, $Ł_0 = (3)$ and three spanning trees, one per edge.

Two theorems, both proved from the single identity $\mathbf{x}^\top Ł \mathbf{x} = \sum_e (x_{u_e} - x_{v_e})^2$ and the single factorization $Ł = \mathbf{N}\mathbf{N}^\top$. The first reads the graph's components off the spectrum of Ł; the

second reads the number of its spanning trees off one determinant, replacing a search over all $\binom{k}{m-1}$ edge sets by one $O(m^3)$ elimination (Proposition 23.2.3 (a)). Both are statements about a graph that no purely combinatorial argument delivers as cheaply.

23.11.5 Exercises

23.11.5.1 A. Check your understanding

Exercise A1.

(a) Define the Laplacian of a graph, and say why it does not depend on the orientation used to define it.

(b) Write down the formula for $\mathbf{x}^\top Ł \mathbf{x}$ as a sum over edges, and deduce that $Ł \succeq 0$.

(c) State the matrix-tree theorem, including all its hypotheses.

(d) True or false: a graph on m vertices is connected if and only if $\operatorname{rank} Ł = m - 1$. Justify your answer.

(e) True or false: if $Ł$ has eigenvalue 0 with multiplicity 1, then $\det Ł_0 > 0$. Justify your answer.

Solution.

(a) With $\mathbf{N}$ the incidence matrix of any orientation, $Ł = \mathbf{N}\mathbf{N}^\top$ (Definition 23.11.1). By Proposition 23.11.1 (a), $Ł = \mathbf{D} - \mathbf{A}$, and the degree matrix and the adjacency matrix are determined by the graph alone.

(b) $\mathbf{x}^\top Ł \mathbf{x} = \sum_e (x_{u_e} - x_{v_e})^2$, where u_e, v_e are the ends of e (Proposition 23.11.1 (b)). This is a sum of squares of real numbers, hence ≥ 0, and $Ł$ is symmetric, so $Ł \succeq 0$ by Definition 12.1.1.

(c) For a graph on $m \geq 2$ vertices with at least one edge, and any vertex r, the matrix $Ł_0$ obtained from $Ł$ by deleting the row and the column of r satisfies $\det Ł_0 =$ the number of spanning trees (Theorem 23.11.8). Multiple edges are allowed; loops are not, since edges join distinct vertices.

(d) True. By Theorem 23.11.2, $\dim \operatorname{nul}(Ł) = c$, the number of components, so Theorem 2.5.7 gives $\operatorname{rank} Ł = m - c$; and $c = 1$ is connectedness.

(e) True. Multiplicity 1 means $c = 1$ by Theorem 23.11.2, so the graph is connected and has at least one spanning tree, and $\det Ł_0 \geq 1$ by Theorem 23.11.8.

23.11.5.2 B. Practice

Exercise B1: The four-cycle.

Let C_4 be the graph on vertices $1, 2, 3, 4$ with edges $\{1,2\}, \{2,3\}, \{3,4\}, \{4,1\}$.

(a) Write down $Ł$ and explain why it is a circulant in the sense of Definition 11.9.1.

(b) Find all eigenvalues of $Ł$, the Fiedler value, and a Fiedler vector.

(c) Compute $\det Ł_0$ and list the spanning trees.

Solution.

(a) Every vertex has degree 2, and the vertices u, v are joined exactly when $v-u \equiv \pm 1 \pmod 4$. So, numbering rows and columns $0,1,2,3$ as in Chapter 11 §09, the (j,k)-entry depends only on $k-j$ modulo 4, which is Definition 11.9.1; the first row is $\mathbf{c} = (2,-1,0,-1)$ and

$$Ł = \begin{pmatrix} 2 & -1 & 0 & -1 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ -1 & 0 & -1 & 2 \end{pmatrix}.$$

(b) By Theorem 11.9.4 the eigenvalues are $p_{\mathbf{c}}(\omega^j)$ for $\omega = i$, with $p_{\mathbf{c}}(x) = 2 - x - x^3$. These were computed in Exercise (B1: Eigenvalues of small circulants) (c): $p_{\mathbf{c}}(1) = 0$, $p_{\mathbf{c}}(i) = 2$, $p_{\mathbf{c}}(-1) = 4$, $p_{\mathbf{c}}(-i) = 2$. In increasing order the eigenvalues are $0,2,2,4$, so the Fiedler value is $\mu_2(Ł) = 2$. A real eigenvector for 2 is twice the real part of the Fourier vector $\mathbf{f}_1 = \frac{1}{2}(1, i, -1, -i)$, namely $(1,0,-1,0)$; it is orthogonal to $\mathbf{1}$, and $Ł(1,0,-1,0) = (2,0,-2,0)$, confirming the eigenvalue. So $(1,0,-1,0)$ is a Fiedler vector, splitting the cycle as $\{1\} \mid \{3\}$ with 2 and 4 undecided.

(c) Deleting the row and column of vertex 4,

$$\det Ł_0 = \det \begin{pmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{pmatrix} = 2(4-1) + 1(-2-0) = 4.$$

Directly: a spanning tree has 3 edges, and the only 3-edge subsets that are not spanning trees would have to contain a cycle; the only cycle is all four edges, so every one of the $\binom{4}{3} = 4$ three-edge subsets is a spanning tree. Both counts give 4.

Exercise B2: Counting trees in a bowtie.

Let G have vertices $1,\dots,5$ and edges $\{1,2\},\{1,3\},\{2,3\},\{3,4\},\{3,5\},\{4,5\}$: two triangles sharing the vertex 3.

(a) Write down Ł and compute $\det Ł_0$ with $r = 1$.

(b) Count the spanning trees directly, and check that the two answers agree.

(c) Verify that $\mathbf{x} = (1,1,0,-1,-1)$ is an eigenvector of Ł, and say what its eigenvalue tells you.

Solution.

(a) The degrees are $2,2,4,2,2$, so

$$Ł = \begin{pmatrix} 2 & -1 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 \\ -1 & -1 & 4 & -1 & -1 \\ 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & -1 & 2 \end{pmatrix}, \qquad Ł_0 = \begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 4 & -1 & -1 \\ 0 & -1 & 2 & -1 \\ 0 & -1 & -1 & 2 \end{pmatrix}.$$

Expanding $\det Ł_0$ along the first row: $2 \det \left(\begin{smallmatrix} 4 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{smallmatrix}\right) + 1 \cdot \det \left(\begin{smallmatrix} -1 & -1 & -1 \\ 0 & 2 & -1 \\ 0 & -1 & 2 \end{smallmatrix}\right)$. The first 3×3 determinant is $4(4-1) + 1(-2-1) - 1(1+2) = 12 - 3 - 3 = 6$, and the second is $-1(4-1) = -3$. So $\det Ł_0 = 12 - 3 = 9$.

(b) Removing the vertex 3 separates the graph into the two triangles, and a set of edges is a spanning tree exactly when it meets each triangle in a spanning tree of that triangle: the two triangles share only the vertex 3, so no cycle can use edges from both, and connectedness of the whole is connectedness of each half through 3. Each triangle has 3 spanning trees, namely its 3 pairs of edges. Hence there are $3 \times 3 = 9$ spanning trees, agreeing with (a).

(c) $Ł\mathbf{x}$ has entries $2-1-0=1$, $-1+2-0=1$, $-1-1+0+1+1=0$, $0-2+1=-1$, $0+1-2=-1$, so $Ł\mathbf{x}=\mathbf{x}$ and the eigenvalue is 1. Since $\mathbf{x}^{\top}\mathbf{1}=0$, Proposition 23.11.4 gives $\mu_2(Ł) \le R_{Ł}(\mathbf{x}) = 1$. The Fiedler value is therefore at most 1, much smaller than the value 5 for the complete graph K_5, computed after Definition 23.11.2, and the sign pattern of $\mathbf{x}$ proposes the partition $\{1,2\} \mid \{4,5\}$ with the shared vertex 3 sitting on the fence: the graph is nearly two pieces.

Exercise B3: Which minors are ± 1?.

Let G be the graph on vertices $1,2,3$ with edges $e_1=\{1,2\}$, $e_2=\{2,3\}$, $e_3=\{1,3\}$, $e_4=\{1,2\}$ (so e_1 and e_4 are parallel). Orient every edge from the smaller vertex to the larger, let $r=3$ and $I=\{1,2\}$.

(a) Write down $\mathbf{N}$ and $\mathbf{N}_0 = \mathbf{N}_{I,[4]}$.

(b) Compute $\det \mathbf{N}_{I,S}$ for all six sets S of two edges, and say in each case whether S is a spanning tree.

(c) Hence find the number of spanning trees, and check it against $\det Ł_0$.

Solution.

(a) Column e has 1 at the tail and -1 at the head:

$$\mathbf{N} = \begin{pmatrix} 1 & 0 & 1 & 1 \\ -1 & 1 & 0 & -1 \\ 0 & -1 & -1 & 0 \end{pmatrix}, \qquad \mathbf{N}_0 = \begin{pmatrix} 1 & 0 & 1 & 1 \\ -1 & 1 & 0 & -1 \end{pmatrix}.$$

(b) Taking the two columns in increasing order each time,

$$\{e_1,e_2\}: \det \begin{pmatrix} 1 & 0 \\ -1 & 1 \end{pmatrix} = 1, \quad \{e_1,e_3\}: \det \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix} = 1,$$
$$\{e_1,e_4\}: \det \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix} = 0, \quad \{e_2,e_3\}: \det \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = -1,$$
$$\{e_2,e_4\}: \det \begin{pmatrix} 0 & 1 \\ 1 & -1 \end{pmatrix} = -1, \quad \{e_3,e_4\}: \det \begin{pmatrix} 1 & 1 \\ 0 & -1 \end{pmatrix} = -1.$$

Five of the six are ± 1 and those five sets are spanning trees: each is a pair of edges covering all three vertices with no cycle. The exception is $\{e_1,e_4\}$, a cycle of length 2 formed by the parallel pair, which misses the vertex 3 entirely; its minor is 0, as Lemma 23.11.6 (c) predicts.

(c) So there are 5 spanning trees. The degrees are $\deg(1)=3$, $\deg(2)=3$, $\deg(3)=2$,

and $a_{12} = 2$, $a_{13} = a_{23} = 1$, so

$$Ł = \begin{pmatrix} 3 & -2 & -1 \\ -2 & 3 & -1 \\ -1 & -1 & 2 \end{pmatrix}, \qquad \det Ł_0 = \det \begin{pmatrix} 3 & -2 \\ -2 & 3 \end{pmatrix} = 9 - 4 = 5.$$

The two answers agree.

23.11.5.3 C. Going deeper

Exercise C1: Cayley's formula.

Let K_m be the complete graph on $m \geq 2$ vertices, in which every pair of distinct vertices is joined by exactly one edge, and let $\mathbf{J}_t \in M_t(\mathbb{R})$ be the all-ones matrix.

(a) Show that the Laplacian of K_m is $m\mathbf{I}_m - \mathbf{J}_m$, and that $Ł_0 = m\mathbf{I}_{m-1} - \mathbf{J}_{m-1}$ for every choice of deleted vertex.

(b) Prove that $\det(m\mathbf{I}_{m-1} - \mathbf{J}_{m-1}) = m^{m-2}$.

(c) Deduce **Cayley's formula**: K_m has exactly m^{m-2} spanning trees. Check it for $m = 2, 3, 4$ against a direct count.

Hint for (b): the eigenvalues of $\mathbf{J}_t$ are visible from its rank and its row sums.

Solution.

(a) Every vertex of K_m has degree $m - 1$ and $a_{uv} = 1$ for $u \neq v$, so by Proposition 23.11.1 (a),

$$Ł = (m-1)\mathbf{I}_m - (\mathbf{J}_m - \mathbf{I}_m) = m\mathbf{I}_m - \mathbf{J}_m.$$

Deleting the row and column of any one vertex from $m\mathbf{I}_m - \mathbf{J}_m$ leaves $m\mathbf{I}_{m-1} - \mathbf{J}_{m-1}$, since the pattern of entries is the same at every vertex.

(b) Put $t = m - 1$. The matrix $\mathbf{J}_t$ is symmetric with every row equal to $\mathbf{1}^\top$, so $\operatorname{rank} \mathbf{J}_t = 1$ and $\dim \operatorname{nul}(\mathbf{J}_t) = t - 1$ by Theorem 2.5.7; hence 0 is an eigenvalue of multiplicity at least $t - 1$. Also $\mathbf{J}_t\mathbf{1} = t\mathbf{1}$, so t is an eigenvalue. That accounts for t eigenvalues, so the eigenvalue list of $\mathbf{J}_t$ is $t, 0, \dots, 0$. Therefore $m\mathbf{I}_t - \mathbf{J}_t$ has eigenvalues $m - t = 1$ once and m with multiplicity $t - 1$, and since $\mathbf{J}_t$ is symmetric it is diagonalizable (Corollary 11.5.2), so

$$\det(m\mathbf{I}_t - \mathbf{J}_t) = 1 \cdot m^{t-1} = m^{m-2}.$$

(c) By Theorem 23.11.8 and parts (a), (b), the number of spanning trees of K_m is $\det Ł_0 = m^{m-2}$. For $m = 2$: $2^0 = 1$, and indeed the single edge is the only spanning tree. For $m = 3$: $3^1 = 3$, and the triangle's spanning trees are its three pairs of edges. For $m = 4$: $4^2 = 16$; directly, K_4 has $\binom{6}{3} = 20$ sets of three edges, of which the 4 triangles are the only ones containing a cycle, leaving $20 - 4 = 16$.

Exercise C2: Weighted graphs.

Give each edge e of a graph G on $m \geq 2$ vertices a weight $w_e > 0$, let $\mathbf{W} = \operatorname{diag}(w_1, \dots, w_k)$, and define the **weighted Laplacian** $Ł^{\mathbf{w}} := \mathbf{N}\mathbf{W}\mathbf{N}^\top$, with $\mathbf{N}$ the incidence matrix of

any orientation.

(a) Prove that $\mathbf{x}^{\top}\text{Ł}^{\mathbf{w}}\mathbf{x} = \sum_e w_e(x_{u_e} - x_{v_e})^2$, and deduce that $\text{Ł}^{\mathbf{w}} \succeq 0$ with the same kernel as Ł.

(b) Prove the weighted matrix-tree theorem: for any vertex r,

$$\det \text{Ł}_0^{\mathbf{w}} = \sum_{T} \prod_{e \in T} w_e,$$

the sum running over all spanning trees T of G.

(c) Check (b) on the graph of Example (A Laplacian computed twice) by comparing the coefficient of $w_1 w_2 w_3$ on both sides, and confirm that setting every $w_e = 1$ recovers Theorem 23.11.8.

Hint for (b): $\mathbf{N}\mathbf{W}\mathbf{N}^{\top} = (\mathbf{N}\mathbf{W}^{1/2})(\mathbf{N}\mathbf{W}^{1/2})^{\top}$.

Solution.

(a) Let $\mathbf{W}^{1/2} = \operatorname{diag}(\sqrt{w_1}, \dots, \sqrt{w_k})$, so $\mathbf{W} = \mathbf{W}^{1/2}\mathbf{W}^{1/2}$ and $\mathbf{W}^{1/2}$ is symmetric. Put $\mathbf{M} = \mathbf{N}\mathbf{W}^{1/2}$. Then $\text{Ł}^{\mathbf{w}} = \mathbf{M}\mathbf{M}^{\top}$ and, as in Proposition 23.11.1 (b),

$$\mathbf{x}^{\top}\text{Ł}^{\mathbf{w}}\mathbf{x} = \|\mathbf{M}^{\top}\mathbf{x}\|^2 = \sum_{e} w_e \big(x_{u_e} - x_{v_e}\big)^2,$$

since entry e of $\mathbf{M}^{\top}\mathbf{x} = \mathbf{W}^{1/2}\mathbf{N}^{\top}\mathbf{x}$ is $\sqrt{w_e}$ times entry e of $\mathbf{N}^{\top}\mathbf{x}$. The matrix is symmetric because $(\mathbf{M}\mathbf{M}^{\top})^{\top} = \mathbf{M}\mathbf{M}^{\top}$, and the sum is ≥ 0, so $\text{Ł}^{\mathbf{w}} \succeq 0$. As in Steps 1 and 2 of the proof of Theorem 23.11.2, $\mathbf{x} \in \operatorname{nul}(\text{Ł}^{\mathbf{w}})$ if and only if this sum vanishes; every w_e is **strictly** positive, so the sum vanishes exactly when every difference $x_{u_e} - x_{v_e}$ does, which is the same condition as for Ł. Hence the kernels agree.

(b) With $\mathbf{M} = \mathbf{N}\mathbf{W}^{1/2}$ as above and $I = [m] \setminus \{r\}$, the argument of Step 1 of Theorem 23.11.8 gives $\text{Ł}_0^{\mathbf{w}} = \mathbf{M}_0\mathbf{M}_0^{\top}$ with $\mathbf{M}_0 = \mathbf{M}_{I,[k]}$. By Corollary 6.7.3,

$$\det \text{Ł}_0^{\mathbf{w}} = \sum_{|S| = m-1} \big(\det \mathbf{M}_{I,S}\big)^2.$$

Multiplying $\mathbf{N}$ on the right by the diagonal matrix $\mathbf{W}^{1/2}$ scales column e by $\sqrt{w_e}$, so $\mathbf{M}_{I,S} = \mathbf{N}_{I,S}\,\mathbf{W}^{1/2}_{S,S}$ and, by Theorem 6.5.4 and Theorem 6.4.6,

$$\big(\det \mathbf{M}_{I,S}\big)^2 = \big(\det \mathbf{N}_{I,S}\big)^2 \prod_{e \in S} w_e.$$

By Lemma 23.11.6 (c) the first factor is 1 when S is a spanning tree and 0 otherwise, and by Proposition 23.11.7 every spanning tree has $m-1$ edges and so occurs among the sets S, once. This gives the formula.

(c) For that graph, with $r = 4$ and the edge numbering $e_1 = \{1,2\}$, $e_2 = \{2,3\}$, $e_3 = \{3,4\}$, $e_4 = \{4,1\}$, $e_5 = \{1,3\}$,

$$\text{Ł}_0^{\mathbf{w}} = \begin{pmatrix} w_1 + w_4 + w_5 & -w_1 & -w_5 \\ -w_1 & w_1 + w_2 & -w_2 \\ -w_5 & -w_2 & w_2 + w_3 + w_5 \end{pmatrix}.$$

The weight w_3 occurs only in the $(3,3)$-entry, so in the Leibniz expansion (Definition 6.4.1) only the two permutations fixing 3 can produce a term containing w_3: the identity, contributing $(w_1+w_4+w_5)(w_1+w_2)(w_2+w_3+w_5)$, and the transposition of 1 and 2, contributing $-(-w_1)(-w_1)(w_2+w_3+w_5)$, every term of which carries a factor w_1^2. So the coefficient of $w_1w_2w_3$ comes from the diagonal product alone, and there it is 1. On the right, a spanning tree T contributes the single monomial $\prod_{e\in T} w_e$, and T is recovered from that monomial, so the coefficient of $w_1w_2w_3$ is 1 if $\{e_1,e_2,e_3\}$ is a spanning tree and 0 otherwise; it is one, as Example (The four-vertex graph, counted both ways) records. Setting every $w_e = 1$ gives $\mathbf{W} = \mathbf{I}$, hence $Ł^{\mathbf{w}} = Ł$, and the right-hand side becomes the number of spanning trees: Theorem 23.11.8.

23.12 The Fast Fourier Transform

Chapter 11 §09 built one unitary matrix, $\mathbf{F}$, that diagonalizes every circulant of its size, and then counted the cost of using it. Forming $\mathbf{Fb}$ as a matrix–vector product takes about n^2 multiplications, so the elegant three-step recipe "transform, divide, transform back" for a circulant system costs $O(n^2)$ — better than elimination, but not dramatically so. The section closed by naming the way out: the powers of ω repeat, splitting one transform of length n into two of length $n/2$ costs almost nothing, and iterating "brings the cost down to about $n \log n$". That algorithm is the **fast Fourier transform**, and Chapter 11 handed it here, "together with the cost accounting that makes 'quickly' precise".

This section pays that debt. There is no new theorem about $\mathbf{F}$ here; there is one matrix identity, proved by computing an entry, and one recurrence, solved exactly.

Throughout, as in Chapter 11 §09, **rows, columns and vector entries are numbered** $0, 1, \dots, n-1$, and $\omega_n := e^{2\pi i/n}$. We write $\mathbf{F}_n$ for the Fourier matrix of size n of Theorem 11.9.3, so $(\mathbf{F}_n)_{jk} = \omega_n^{jk}/\sqrt{n}$; Chapter 11 wrote it $\mathbf{F}$, the size being fixed there.

23.12.1 Counting the cost of a transform

Chapter 11 §09 defined the **discrete Fourier transform** of $\mathbf{c} \in \mathbb{C}^n$ to be $\widehat{\mathbf{c}} = \sqrt{n}\,\mathbf{F}_n\mathbf{c}$, the vector of eigenvalues $p_{\mathbf{c}}(\omega_n^j)$ of the circulant with first row $\mathbf{c}$. It is the unnormalized transform that the algorithm computes, so it is convenient to give its matrix a name of its own.

Definition 23.12.1 — The transform matrix

For $n \geq 1$ let

$$\mathbf{W}_n := \sqrt{n}\,\mathbf{F}_n \in M_n(\mathbb{C}), \qquad (\mathbf{W}_n)_{jk} = \omega_n^{jk} \quad (0 \leq j,k \leq n-1),$$

so that $\widehat{\mathbf{c}} = \mathbf{W}_n\mathbf{c}$ for every $\mathbf{c} \in \mathbb{C}^n$.

A **cost** in this section is a count of arithmetic operations, where one complex addition, one complex subtraction, one complex multiplication and one complex division each count as **one operation**; a multiplication by the constant 1 is free, because it is not performed. What is being counted is the work of applying $\mathbf{W}_n$ to an arbitrary vector, not the work of writing $\mathbf{W}_n$

down.

Applying $\mathbf{W}_n$ as a plain matrix–vector product costs

$$n^2 \text{ multiplications} + n(n-1) \text{ additions} = 2n^2 - n$$

operations: each of the n entries of $\mathbf{W}_n\mathbf{c}$ is a sum of n products. This figure charges every one of those products, including the $2n-1$ whose factor is an entry $\omega_n^0 = 1$ of row 0 or column 0; it is the plain matrix–vector product as it is ordinarily performed, and the comparisons below use it as it stands. For $n = 1024$ that is 2 096 128 operations. The whole of this section is about replacing that number by about 15 000.

23.12.2 Splitting a transform in two

Where can a saving possibly come from? The entries of $\mathbf{W}_n$ are powers of ω_n, and there are only n distinct ones, so the n^2 products $\omega_n^{jk}c_k$ involve enormous repetition. The single algebraic fact that organizes the repetition is

$$\omega_n^2 = e^{4\pi i/n} = e^{2\pi i/m} = \omega_m, \qquad \text{where } n = 2m.$$

Squaring a primitive n-th root of unity gives a primitive m-th root of unity. So if we separate the even-numbered entries of $\mathbf{c}$ from the odd-numbered ones, the even half is transformed by $\mathbf{W}_m$, not by anything new. Two objects give the bookkeeping a name.

Definition 23.12.2 — The even-odd permutation, the twiddle matrix and the butterfly

Let $n = 2m$ with $m \geq 1$.

(a) The **even-odd permutation matrix** $\mathbf{P}_n \in M_n(\mathbb{C})$ is the permutation matrix determined by

$$(\mathbf{P}_n\mathbf{x})_t = x_{2t}, \qquad (\mathbf{P}_n\mathbf{x})_{m+t} = x_{2t+1} \qquad (0 \leq t \leq m-1);$$

it lists the even-numbered entries of $\mathbf{x}$ first, then the odd-numbered ones, each in their original order.

(b) The **twiddle matrix** is $\mathbf{D}_m := \operatorname{diag}\bigl(1, \omega_n, \omega_n^2, \dots, \omega_n^{m-1}\bigr) \in M_m(\mathbb{C})$. Its entries are powers of ω_n, **not** of ω_m.

(c) The **butterfly matrix** is

$$\mathbf{B}_n := \begin{pmatrix} \mathbf{I}_m & \mathbf{D}_m \\ \mathbf{I}_m & -\mathbf{D}_m \end{pmatrix} \in M_n(\mathbb{C}).$$

In words: $\mathbf{P}_n$ is pure data movement and does no arithmetic; $\mathbf{D}_m$ supplies the m twiddles that the odd half needs because it starts one place late; and $\mathbf{B}_n$ forms the m sums and the m differences that recombine the two halves. Applied to a vector $(\mathbf{u}, \mathbf{v})$ split into two halves of length m, the butterfly returns $(\mathbf{u} + \mathbf{D}_m\mathbf{v},\ \mathbf{u} - \mathbf{D}_m\mathbf{v})$.

Theorem 23.12.1 — The Radix-Two Factorization

Let $n = 2m$ with $m \geq 1$. Then

$$\mathbf{W}_n = \mathbf{B}_n \begin{pmatrix} \mathbf{W}_m & 0 \\ 0 & \mathbf{W}_m \end{pmatrix} \mathbf{P}_n.$$

Equivalently, for the unitary Fourier matrices,

$$\mathbf{F}_n = \frac{1}{\sqrt{2}}\, \mathbf{B}_n \begin{pmatrix} \mathbf{F}_m & 0 \\ 0 & \mathbf{F}_m \end{pmatrix} \mathbf{P}_n.$$

Idea. Apply both sides to an arbitrary $\mathbf{x}$ and compute entry j of the left side. Split the defining sum $\sum_k \omega_n^{jk} x_k$ into its even $k = 2t$ and odd $k = 2t+1$ parts; the relation $\omega_n^2 = \omega_m$ turns each part into a transform of length m, and the odd part carries one spare factor ω_n^j. That is the whole computation, and it already gives the top half of the answer. For the bottom half, write $j = m + i$; the relation $\omega_m^m = 1$ makes the two transforms of length m repeat what they gave at i, while $\omega_n^m = -1$ flips the sign of the spare factor. Sum and difference: the butterfly.

Proof. Let $\mathbf{x} \in \mathbb{C}^n$ and put

$$\mathbf{u} := \mathbf{W}_m\big(x_0, x_2, \ldots, x_{n-2}\big), \qquad \mathbf{v} := \mathbf{W}_m\big(x_1, x_3, \ldots, x_{n-1}\big),$$

so that $u_i = \sum_{t=0}^{m-1} \omega_m^{it} x_{2t}$ and $v_i = \sum_{t=0}^{m-1} \omega_m^{it} x_{2t+1}$ for $0 \leq i \leq m-1$, by Definition 23.12.1. By Definition 23.12.2 (a), $\mathbf{P}_n\mathbf{x}$ is exactly the pair of these two argument vectors stacked, so the right-hand side applied to $\mathbf{x}$ is $\mathbf{B}_n(\mathbf{u}, \mathbf{v}) = (\mathbf{u} + \mathbf{D}_m\mathbf{v},\ \mathbf{u} - \mathbf{D}_m\mathbf{v})$.

Now compute entry j of $\mathbf{W}_n\mathbf{x}$. Splitting the index k into $k = 2t$ and $k = 2t+1$ with $0 \leq t \leq m-1$, and using $\omega_n^2 = \omega_m$,

$$\begin{aligned} (\mathbf{W}_n\mathbf{x})_j &= \sum_{k=0}^{n-1} \omega_n^{jk} x_k = \sum_{t=0}^{m-1} \omega_n^{2jt} x_{2t} + \sum_{t=0}^{m-1} \omega_n^{j(2t+1)} x_{2t+1} \\ &= \sum_{t=0}^{m-1} \omega_m^{jt} x_{2t} + \omega_n^j \sum_{t=0}^{m-1} \omega_m^{jt} x_{2t+1}. \end{aligned}$$

Top half. For $0 \leq j \leq m-1$ the two sums are u_j and v_j, so

$$(\mathbf{W}_n\mathbf{x})_j = u_j + \omega_n^j v_j = \big(\mathbf{u} + \mathbf{D}_m\mathbf{v}\big)_j,$$

the last equality by Definition 23.12.2 (b), the j-th diagonal entry of $\mathbf{D}_m$ being ω_n^j.

Bottom half. For $j = m + i$ with $0 \leq i \leq m-1$, we have $\omega_m^{jt} = \omega_m^{mt}\omega_m^{it} = \omega_m^{it}$, since $\omega_m^m = 1$; so both sums repeat their values at i, namely u_i and v_i. The spare factor is

$$\omega_n^{m+i} = \omega_n^m\, \omega_n^i = e^{\pi i}\, \omega_n^i = -\omega_n^i,$$

because $\omega_n^m = e^{2\pi i m/n} = e^{\pi i} = -1$. Hence

$$(\mathbf{W}_n\mathbf{x})_{m+i} = u_i - \omega_n^i v_i = \big(\mathbf{u} - \mathbf{D}_m\mathbf{v}\big)_i.$$

The two halves together say that $\mathbf{W}_n\mathbf{x}$ equals the right-hand side applied to $\mathbf{x}$, for every $\mathbf{x} \in \mathbb{C}^n$; so the two matrices are equal. For the second display, substitute $\mathbf{W}_n = \sqrt{n}\,\mathbf{F}_n$ and $\mathbf{W}_m = \sqrt{m}\,\mathbf{F}_m$ and divide by $\sqrt{n}$, using $\sqrt{m}/\sqrt{n} = 1/\sqrt{2}$.

■

The identity is a factorization of one matrix into three, and each of the three is cheap for a different reason: $\mathbf{P}_n$ does no arithmetic, the middle factor is two copies of a **smaller instance of the same problem**, and $\mathbf{B}_n$ costs $O(n)$. That is the entire content of the fast Fourier transform. Everything below is bookkeeping.

Quick check. Write out Theorem 23.12.1 for $n = 2$ and check it directly.

Solution. Here $m = 1$, so $\mathbf{P}_2 = \mathbf{I}_2$ (it lists x_0 then x_1), $\mathbf{W}_1 = (1)$, and $\mathbf{D}_1 = (\omega_2^0) = (1)$. Hence

$$\mathbf{B}_2 = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix},$$

and the right-hand side is $\mathbf{B}_2\mathbf{I}_2\mathbf{I}_2 = \mathbf{B}_2$. And $(\mathbf{W}_2)_{jk} = \omega_2^{jk} = (-1)^{jk}$, which is the same matrix.

Example. (The factorization for $n = 4$)

Write out Theorem 23.12.1 for $n = 4$, and check it against the matrix $\mathbf{F}$ of Example (The Fourier matrix of size four).

Solution. Here $m = 2$ and $\omega_4 = i$, so $\mathbf{D}_2 = \operatorname{diag}(1, i)$ and

$$\mathbf{B}_4 = \begin{pmatrix} 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & i \\ 1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -i \end{pmatrix}, \quad \mathbf{P}_4 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \mathbf{W}_2 = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}.$$

Multiplying, $\begin{pmatrix} \mathbf{W}_2 & 0 \\ 0 & \mathbf{W}_2 \end{pmatrix}\mathbf{P}_4$ has rows $(1,0,1,0)$, $(1,0,-1,0)$, $(0,1,0,1)$, $(0,1,0,-1)$. Applying $\mathbf{B}_4$ adds row 3 to row 1, adds i times row 4 to row 2, and so on, giving

$$\mathbf{B}_4 \begin{pmatrix} \mathbf{W}_2 & 0 \\ 0 & \mathbf{W}_2 \end{pmatrix} \mathbf{P}_4 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & i & -1 & -i \\ 1 & -1 & 1 & -1 \\ 1 & -i & -1 & i \end{pmatrix} = \mathbf{W}_4,$$

whose (j,k)-entry is i^{jk}. Dividing by $\sqrt{4} = 2$ returns the matrix $\mathbf{F} = \frac{1}{2}\mathbf{W}_4$ written out in Example (The Fourier matrix of size four).

Warning. **The twiddles are powers of ω_n, not of ω_m.** If $\mathbf{D}_2$ in Example (The factorization for $n = 4$) is taken to be $\operatorname{diag}(1, \omega_2) = \operatorname{diag}(1, -1)$, the product becomes the **real** matrix with rows $(1,1,1,1)$, $(1,-1,-1,1)$, $(1,-1,1,-1)$, $(1,1,-1,-1)$, whereas the second row of $\mathbf{W}_4$ is $(1, i, -1, -i)$. The single factor ω_n^j in the proof is what remembers that the odd-numbered entries start one step later, and it is the only place where the transform of size n differs from two transforms of size m.

23.12.3 The cost, exactly

Read Theorem 23.12.1 from right to left as a procedure.

Algorithm. **Input.** $\mathbf{x} \in \mathbb{C}^n$, with $n = 2^p$ a power of two.

Output. $\mathbf{W}_n\mathbf{x}$.

1. If $n = 1$, return $\mathbf{x}$.
2. Split $\mathbf{x}$ into its even-numbered and odd-numbered entries (no arithmetic).
3. Compute $\mathbf{u}$ and $\mathbf{v}$, the transforms of the two halves, by applying this procedure to each of them.
4. Multiply: set $v'_0 := v_0$, and $v'_i := \omega_n^i v_i$ for $1 \le i \le m-1$, where $m = n/2$.
5. Return $(\mathbf{u} + \mathbf{v}',\ \mathbf{u} - \mathbf{v}')$.

The procedure returns $\mathbf{W}_n\mathbf{x}$ for every $n = 2^p$, by induction on p: for $p = 0$ step 1 returns $\mathbf{x} = \mathbf{W}_1\mathbf{x}$, and for $n = 2m$ the inductive hypothesis makes the $\mathbf{u}$ and $\mathbf{v}$ of step 3 the two transforms of length m named in the proof of Theorem 23.12.1, so steps 4 and 5 return $(\mathbf{u}+\mathbf{D}_m\mathbf{v},\ \mathbf{u}-\mathbf{D}_m\mathbf{v})$, which that proof identifies with $\mathbf{W}_n\mathbf{x}$. What is left is the cost.

Theorem 23.12.2 — The Cost of the Fast Fourier Transform

Let $C(n)$ be the number of operations the procedure above performs on an input of length $n = 2^p$, with $p \ge 0$. Then $C(1) = 0$,

$$C(2m) = 2C(m) + 3m - 1 \qquad (m \ge 1),$$

and the solution of this recurrence is exactly

$$C(2^p) = \tfrac{3}{2}\,p\,2^p - 2^p + 1, \qquad \text{that is} \qquad C(n) = \tfrac{3}{2}\,n\log_2 n - n + 1.$$

In particular $C(n) = O(n \log n)$.

Idea. Step 3 is where the recursion sits and contributes $2C(m)$; steps 4 and 5 are the only arithmetic outside it, and both are linear in n. Count them once, carefully: step 4 is $m-1$ multiplications, the factor $\omega_n^0 = 1$ at $i = 0$ not being applied at all, and step 5 is m additions and m subtractions. Then solve the recurrence by induction on p, which works because the recursion halves the length exactly.

Proof. For $n = 1$ the procedure returns its input and does nothing, so $C(1) = 0$.

Let $n = 2m$ with $m \ge 1$. Step 2 only moves data. Step 3 calls the procedure twice on length m, costing $2C(m)$. Step 4 copies v_0, which is no arithmetic, and forms $\omega_n^i v_i$ for $i = 1, \dots, m-1$, which is $m-1$ multiplications. Step 5 forms m sums and m differences, which is $2m$ operations. Adding,

$$C(2m) = 2C(m) + (m-1) + 2m = 2C(m) + 3m - 1.$$

Now induct on p. For $p = 0$, the formula gives $\frac{3}{2} \cdot 0 \cdot 1 - 1 + 1 = 0 = C(1)$. Let $p \ge 1$

and suppose $C(2^{p-1}) = \frac{3}{2}(p-1)2^{p-1} - 2^{p-1} + 1$. Taking $m = 2^{p-1}$ in the recurrence,

$$\begin{aligned} C(2^p) &= 2\Big(\tfrac{3}{2}(p-1)2^{p-1} - 2^{p-1} + 1\Big) + 3 \cdot 2^{p-1} - 1 \\ &= \tfrac{3}{2}(p-1)2^p - 2^p + 2 + \tfrac{3}{2} \cdot 2^p - 1 \\ &= \tfrac{3}{2}p\,2^p - 2^p + 1, \end{aligned}$$

where the last line collects $\frac{3}{2}(p-1)2^p + \frac{3}{2}2^p = \frac{3}{2}p2^p$. This completes the induction. Substituting $n = 2^p$, so $p = \log_2 n$, gives the stated formula, and $\frac{3}{2}n\log_2 n - n + 1 \le \frac{3}{2}n\log_2 n$ for $n \ge 1$, so $C(n) = O(n \log n)$.

■

The exact formula is worth tabulating against the $2n^2 - n$ of a plain matrix–vector product.

n	$C(n)$	$2n^2 - n$
2	2	6
8	29	120
32	209	2 016
1024	14 337	2 096 128

At $n = 1024$ the ratio is about 146, and it grows without bound, because $(2n^2 - n)/C(n)$ behaves like $\frac{4}{3}n/\log_2 n$. This is the sense in which the transform can be applied "quickly": the exponent drops from 2 to 1, up to a logarithm, and the constant $\frac{3}{2}$ in front is small.

Warning. **The recursion needs n even at every level, so $n = 2^p$ is the clean case.** For n odd and greater than 1 the factorization of Theorem 23.12.1 does not apply at all, and the procedure above cannot start. For $n = 2^a q$ with q odd, it descends a levels and then must transform vectors of length q some other way; if q is large, nothing has been gained. The remedy is either to split by other factors of n, as in Exercise (C1: Splitting into three), or, for the convolution use below, to pad with zeros up to the next power of two — which at most doubles n and so changes the cost by a bounded factor.

Example. (A transform of length eight)

Compute $\mathbf{W}_8\mathbf{c}$ for $\mathbf{c} = (1, 2, 3, 4, 1, 2, 3, 4)$ by the procedure, showing every level, and check the result against the direct definition at one entry.

Solution. Level 1. The even-numbered entries are $(1, 3, 1, 3)$ and the odd-numbered ones are $(2, 4, 2, 4)$.

Level 2, applied to $(1, 3, 1, 3)$. Its even and odd halves are $(1, 1)$ and $(3, 3)$, whose transforms are $\mathbf{W}_2(1, 1) = (2, 0)$ and $\mathbf{W}_2(3, 3) = (6, 0)$. Here $n = 4$, so $\mathbf{D}_2 = \operatorname{diag}(1, i)$ and $\mathbf{D}_2(6, 0) = (6, 0)$. The butterfly gives $(2 + 6,\ 0 + 0,\ 2 - 6,\ 0 - 0) = (8, 0, -4, 0)$. So $\mathbf{u} = (8, 0, -4, 0)$.

Level 2, applied to $(2, 4, 2, 4)$. Its even and odd halves are $(2, 2)$ and $(4, 4)$, whose transforms are $\mathbf{W}_2(2, 2) = (4, 0)$ and $\mathbf{W}_2(4, 4) = (8, 0)$. Again $n = 4$ and $\mathbf{D}_2(8, 0) = (8, 0)$, so the butterfly gives $(4 + 8,\ 0,\ 4 - 8,\ 0)$. So $\mathbf{v} = (12, 0, -4, 0)$.

Level 1, recombination. Now $n = 8$ and $\mathbf{D}_4 = \operatorname{diag}(1, \omega_8, i, \omega_8^3)$ with $\omega_8 = e^{\pi i/4}$, so

$$\mathbf{D}_4\mathbf{v} = (12,\ 0,\ -4i,\ 0),$$

the irrational entries of $\mathbf{D}_4$ never appearing because $v_1 = v_3 = 0$. The butterfly gives

$$\mathbf{W}_8\mathbf{c} = \big(20,\ 0,\ -4-4i,\ 0,\ -4,\ 0,\ -4+4i,\ 0\big).$$

Check at $j = 2$. By Definition 23.12.1, $(\mathbf{W}_8\mathbf{c})_2 = \sum_k \omega_8^{2k} c_k = \sum_k i^k c_k$ since $\omega_8^2 = i$. This is

$$1 + 2i - 3 - 4i + 1 + 2i - 3 - 4i = -4 - 4i,$$

matching. The zeros in the odd positions are not an accident. Since $\mathbf{c}$ repeats with period 4, that is $c_{k+4} = c_k$, splitting the defining sum at $k = 4$ gives

$$(\mathbf{W}_8\mathbf{c})_j = \sum_{k=0}^{3} c_k\big(\omega_8^{jk} + \omega_8^{j(k+4)}\big) = \big(1 + (-1)^j\big)\sum_{k=0}^{3} \omega_8^{jk} c_k,$$

using $\omega_8^{4j} = (e^{\pi i})^j = (-1)^j$. The factor $1 + (-1)^j$ is 0 at every odd j.

23.12.4 What the speed buys

Two corollaries, both immediate now, and both paying off Chapter 11 §09.

Chapter 11 §09 proved the Convolution Theorem: $\widehat{\mathbf{c} * \mathbf{d}} = \widehat{\mathbf{c}} \odot \widehat{\mathbf{d}}$ entrywise (Theorem 11.9.6 (b)). Before this section that identity converted an $O(n^2)$ convolution into three $O(n^2)$ transforms, which is no gain at all. With Theorem 23.12.2 it becomes a genuine algorithm.

Corollary 23.12.3 — Convolution in $O(n \log n)$

Let $n = 2^p$. The cyclic convolution $\mathbf{c} * \mathbf{d}$ of two vectors in $\mathbb{C}^n$ can be computed in

$$3C(n) + 2n = \tfrac{9}{2}\, n \log_2 n - n + 3$$

operations, where C is as in Theorem 23.12.2. Consequently, the product of two polynomials in $\mathbb{C}[x]$ of degree at most d can be computed in $O(d \log d)$ operations.

Proof. **The inverse transform costs the same.** By Theorem 11.9.3, $\mathbf{F}_n^{-1} = \mathbf{F}_n^*$, and $\mathbf{F}_n$ is symmetric because $(\mathbf{F}_n)_{jk} = \omega_n^{jk}/\sqrt{n}$ is unchanged by swapping j and k; hence $\mathbf{F}_n^* = \overline{\mathbf{F}_n}$ and

$$\mathbf{W}_n^{-1} = \tfrac{1}{\sqrt{n}}\mathbf{F}_n^{-1} = \tfrac{1}{\sqrt{n}}\overline{\mathbf{F}_n} = \tfrac{1}{n}\overline{\mathbf{W}_n}.$$

Conjugating the identity of Theorem 23.12.1 entry by entry, and noting that $\mathbf{P}_n$ is real, gives

$$\overline{\mathbf{W}_n} = \overline{\mathbf{B}_n}\begin{pmatrix} \overline{\mathbf{W}_m} & 0 \\ 0 & \overline{\mathbf{W}_m} \end{pmatrix}\mathbf{P}_n,$$

which is the same factorization with every ω_n replaced by $\overline{\omega_n} = \omega_n^{-1}$. The procedure therefore runs verbatim with ω_n^{-1} in place of ω_n and computes $\overline{\mathbf{W}_n}\mathbf{y}$ in $C(n)$ operations.

The algorithm. By Theorem 11.9.6 (b) and the definition $\widehat{\mathbf{c}} = \mathbf{W}_n\mathbf{c}$,

$$\mathbf{W}_n(\mathbf{c} * \mathbf{d}) = (\mathbf{W}_n\mathbf{c}) \odot (\mathbf{W}_n\mathbf{d}), \qquad \text{so} \qquad \mathbf{c} * \mathbf{d} = \tfrac{1}{n}\,\overline{\mathbf{W}_n}\big((\mathbf{W}_n\mathbf{c}) \odot (\mathbf{W}_n\mathbf{d})\big).$$

Computing $\mathbf{W}_n\mathbf{c}$ and $\mathbf{W}_n\mathbf{d}$ costs $2C(n)$; the n entrywise products cost n; the inverse transform costs $C(n)$; the n divisions by n cost n. The total is $3C(n) + 2n$, and substituting the formula of Theorem 23.12.2 gives $\frac{9}{2}n\log_2 n - 3n + 3 + 2n$, as stated.

Polynomials. Let $p = \sum_{l=0}^{d} p_l x^l$ and $q = \sum_{l=0}^{d} q_l x^l$, and choose $n = 2^P$ with $n \geq 2d+1$ and $n < 4d+2$, which is possible since the powers of two are spaced by a factor of two. Let $\mathbf{c}, \mathbf{d} \in \mathbb{C}^n$ be the coefficient vectors padded with zeros. The coefficient of x^r in pq, for $0 \leq r \leq 2d$, is $\sum_l c_l d_{r-l}$ summed over $0 \leq l \leq r$, while $(\mathbf{c} * \mathbf{d})_r = \sum_{l=0}^{n-1} c_l d_{r-l}$ with the subscript read modulo n. The two agree: a term of the second sum with $l > r$ has d-subscript $r - l + n$, and it can be non-zero only if $l \leq d$ and $r - l + n \leq d$, which forces $n \leq d + l - r \leq 2d$, contradicting $n \geq 2d+1$. So the coefficients of pq are the first $2d+1$ entries of $\mathbf{c} * \mathbf{d}$, computable in $3C(n) + 2n$ operations with $n < 4d+2$, which is $O(d \log d)$.

■

Warning. **Convolution wraps around; polynomial multiplication does not.** Padding to length $n \geq 2d+1$ is not a convenience, it is the hypothesis. Take $p = q = 1 + x$, so $d = 1$, and convolve the unpadded vectors $\mathbf{c} = \mathbf{d} = (1, 1)$ in $\mathbb{C}^2$: the answer is $(c_0d_0 + c_1d_1,\ c_0d_1 + c_1d_0) = (2, 2)$, the coefficient vector of $2 + 2x$, whereas $(1+x)^2 = 1+2x+x^2$. The x^2 term has wrapped around onto the constant term, because in $\mathbb{C}^n$ the exponents are read modulo n and $x^2 \equiv 1$. Padding to $\mathbf{c} = \mathbf{d} = (1, 1, 0, 0)$ in $\mathbb{C}^4$ gives $(1, 2, 1, 0)$, which is right.

Corollary 23.12.4 — Solving a Circulant System in $O(n \log n)$

Let $n = 2^p$, let $\mathbf{C} \in M_n(\mathbb{C})$ be an invertible circulant with first row $\mathbf{c}$, and let $\mathbf{b} \in \mathbb{C}^n$. Then the solution of $\mathbf{C}\mathbf{x} = \mathbf{b}$ can be computed in $3C(n) + 2n$ operations.

Proof. By Theorem 11.9.4, $\mathbf{C} = \mathbf{F}_n\mathbf{\Lambda}\mathbf{F}_n^*$ with $\mathbf{\Lambda} = \operatorname{diag}(p_{\mathbf{c}}(1), \dots, p_{\mathbf{c}}(\omega_n^{n-1}))$, and the diagonal of $\mathbf{\Lambda}$ is exactly $\widehat{\mathbf{c}} = \mathbf{W}_n\mathbf{c}$; the letter $\mathbf{D}$ is reserved here for the twiddle matrix of Definition 23.12.2. Since $\mathbf{C}$ is invertible, every $\widehat{c}_j \neq 0$ by Corollary 11.9.5 (d), so $\mathbf{\Lambda}^{-1}$ exists and

$$\mathbf{x} = \mathbf{C}^{-1}\mathbf{b} = \mathbf{F}_n\mathbf{\Lambda}^{-1}\mathbf{F}_n^*\mathbf{b} = \tfrac{1}{n}\,\mathbf{W}_n\Big(\big(\overline{\mathbf{W}_n}\mathbf{b}\big) \oslash \widehat{\mathbf{c}}\Big),$$

where $\oslash$ is entrywise division and the last equality uses $\mathbf{F}_n = n^{-1/2}\mathbf{W}_n$ and $\mathbf{F}_n^* = n^{-1/2}\overline{\mathbf{W}_n}$, as in the proof of Corollary 23.12.3. The three transforms cost $C(n)$ each, by Theorem 23.12.2 and the first part of that proof; the n divisions and the n final scalings by $1/n$ cost $2n$. Sanity check at $\mathbf{C} = \mathbf{I}_n$: then $\mathbf{c} = \mathbf{e}_0$, $\widehat{\mathbf{c}} = (1, \dots, 1)$, and the formula returns $\frac{1}{n}\mathbf{W}_n\overline{\mathbf{W}_n}\mathbf{b} = \frac{1}{n}(n\mathbf{I}_n)\mathbf{b} = \mathbf{b}$, using $\mathbf{W}_n\overline{\mathbf{W}_n} = n\mathbf{F}_n\mathbf{F}_n^* = n\mathbf{I}_n$.

■

Remark. None of this is a new theorem about the discrete Fourier transform. The matrix $\mathbf{F}_n$, the factorization $\mathbf{C} = \mathbf{F}_n\mathbf{\Lambda}\mathbf{F}_n^*$ of Theorem 11.9.4 and the Convolution Theorem (Theorem 11.9.6) are exactly as Chapter 11 left them; Theorem 23.12.1 is an identity

between matrices all of which were already known, and Theorem 23.12.2 counts operations. The transform is a change of basis, and the fast Fourier transform is a way of applying that change of basis in $O(n \log n)$ operations instead of $O(n^2)$. What changes is not what can be computed but what can be computed at the sizes that occur.

23.12.5 Exercises

23.12.5.1 A. Check your understanding

Exercise A1.

(a) Write down the matrix $\mathbf{W}_n$, and say how it is related to the Fourier matrix $\mathbf{F}_n$ of Chapter 11.

(b) State Theorem 23.12.1, and say what each of the three factors on the right costs to apply.

(c) How many operations does $\mathbf{W}_n\mathbf{x}$ cost as a plain matrix–vector product, and how many by the fast algorithm when $n = 2^p$?

(d) True or false: the fast Fourier transform computes a different transform from the one in Chapter 11, which is why it is faster. Justify your answer.

(e) Why does the algorithm require n to be a power of two, and what is done when it is not?

Solution.

(a) $\mathbf{W}_n = \sqrt{n}\,\mathbf{F}_n$, with $(\mathbf{W}_n)_{jk} = \omega_n^{jk}$ for $0 \le j, k \le n-1$ and $\omega_n = e^{2\pi i/n}$ (Definition 23.12.1). It is the matrix of the discrete Fourier transform $\mathbf{c} \mapsto \widehat{\mathbf{c}}$ of Chapter 11 §09.

(b) $\mathbf{W}_n = \mathbf{B}_n \begin{pmatrix} \mathbf{W}_m & 0 \\ 0 & \mathbf{W}_m \end{pmatrix} \mathbf{P}_n$ for $n = 2m$. Applying $\mathbf{P}_n$ costs nothing, since it only moves entries; the middle factor costs two transforms of length m; and $\mathbf{B}_n$ costs $m-1$ multiplications and $2m$ additions and subtractions.

(c) Directly: n^2 multiplications and $n(n-1)$ additions, that is $2n^2 - n$. By the algorithm: $C(n) = \frac{3}{2} n \log_2 n - n + 1$ (Theorem 23.12.2).

(d) False. Theorem 23.12.1 is an identity between matrices, so the algorithm returns $\mathbf{W}_n\mathbf{x}$ exactly, in exact arithmetic. It is faster because it applies the same matrix by a cheaper route, not because it computes something else.

(e) The factorization needs $n = 2m$, and the recursion needs that at every level, so it needs $n = 2^p$. For other n one either pads with zeros to the next power of two, which is legitimate for convolution provided the padded length still exceeds the degree of the product (see the warning after Corollary 23.12.3), or splits by a different factor of n, as in Exercise (C1: Splitting into three).

23.12.5.2 B. Practice

Exercise B1: A transform of length four.

Let $\mathbf{c} = (1, 1, -1, -1) \in \mathbb{C}^4$.

(a) Compute $\mathbf{W}_4\mathbf{c}$ by the procedure of this section, showing the two halves and the twiddles.

(b) Check the answer by evaluating the symbol $p_{\mathbf{c}}$ at the fourth roots of unity.

(c) Count the operations your computation in (a) used, and compare with $C(4)$.

Solution.

(a) The even-numbered entries are $(1,-1)$ and the odd-numbered ones are $(1,-1)$. Both transform to $\mathbf{W}_2(1,-1) = (1-1,\ 1+1) = (0,2)$, so $\mathbf{u} = \mathbf{v} = (0,2)$. With $n = 4$, $\mathbf{D}_2 = \operatorname{diag}(1,i)$, so $\mathbf{D}_2\mathbf{v} = (0,2i)$. The butterfly gives

$$\mathbf{W}_4\mathbf{c} = \big(0+0,\ 2+2i,\ 0-0,\ 2-2i\big) = (0,\ 2+2i,\ 0,\ 2-2i).$$

(b) The symbol is $p_{\mathbf{c}}(x) = 1 + x - x^2 - x^3$ (Definition 11.9.1), and $\widehat{c}_j = p_{\mathbf{c}}(i^j)$. Then $p_{\mathbf{c}}(1) = 1+1-1-1 = 0$; $p_{\mathbf{c}}(i) = 1+i+1+i = 2+2i$, using $-i^2 = 1$ and $-i^3 = i$; $p_{\mathbf{c}}(-1) = 1-1-1+1 = 0$; and $p_{\mathbf{c}}(-i) = 1-i+1-i = 2-2i$. The four values agree with (a).

(c) Each $\mathbf{W}_2$ costs 2 operations (one sum, one difference), so the two halves cost 4; the twiddles cost 1, since the factor 1 is free and only $i \cdot 2$ is a multiplication; the final butterfly costs 4. The total is 9, and $C(4) = \frac{3}{2} \cdot 4 \cdot 2 - 4 + 1 = 9$. A direct matrix–vector product would cost $2 \cdot 16 - 4 = 28$.

Exercise B2: A transform of length eight.

Let $\mathbf{c} = (2,1,0,3,2,1,0,3) \in \mathbb{C}^8$. Compute $\mathbf{W}_8\mathbf{c}$ by the procedure, showing both levels, and verify entry $j = 2$ directly from Definition 23.12.1.

Solution. Level 1. Even-numbered entries $(2,0,2,0)$; odd-numbered entries $(1,3,1,3)$.

Level 2 on $(2,0,2,0)$. Halves $(2,2)$ and $(0,0)$, with transforms $(4,0)$ and $(0,0)$. Here the inner n is 4, so $\mathbf{D}_2 = \operatorname{diag}(1,i)$ and $\mathbf{D}_2(0,0) = (0,0)$. The butterfly gives $\mathbf{u} = (4,0,4,0)$.

Level 2 on $(1,3,1,3)$. Halves $(1,1)$ and $(3,3)$, with transforms $(2,0)$ and $(6,0)$; $\mathbf{D}_2(6,0) = (6,0)$; the butterfly gives $\mathbf{v} = (8,0,-4,0)$.

Level 1, recombination. Now $n = 8$ and $\mathbf{D}_4 = \operatorname{diag}(1,\omega_8,i,\omega_8^3)$, so $\mathbf{D}_4\mathbf{v} = (8,0,-4i,0)$. Hence

$$\begin{aligned}\mathbf{W}_8\mathbf{c} &= (4+8,\ 0,\ 4-4i,\ 0,\ 4-8,\ 0,\ 4+4i,\ 0)\\ &= (12,0,4-4i,0,-4,0,4+4i,0).\end{aligned}$$

Check at $j = 2$. Since $\omega_8^2 = i$, Definition 23.12.1 gives $(\mathbf{W}_8\mathbf{c})_2 = \sum_k i^k c_k = 2 + i + 0 - 3i + 2 + i + 0 - 3i = 4 - 4i$, as computed.

Exercise B3: A product of polynomials by convolution.

Let $p = 1 + 2x + 3x^2$ and $q = 2 + x$ in $\mathbb{C}[x]$.

(a) What is the smallest power of two n for which the recipe in the proof of Corollary 23.12.3 is valid? Write down the padded coefficient vectors $\mathbf{c}$ and $\mathbf{d}$.

(b) Compute $\mathbf{c} * \mathbf{d}$ directly from the definition of cyclic convolution, and read off pq.

(c) Show that using $n = 3$ instead would give the wrong answer, and identify which coefficient wraps onto which.

Solution.

(a) The product pq has degree 3, so 4 coefficients are needed and any $n \geq 4$ works; the smallest power of two is $n = 4$. The padded vectors are $\mathbf{c} = (1, 2, 3, 0)$ and $\mathbf{d} = (2, 1, 0, 0)$.

(b) With subscripts modulo 4 and $d_0 = 2$, $d_1 = 1$, $d_2 = d_3 = 0$, the sum $(\mathbf{c} * \mathbf{d})_r = \sum_l c_l d_{r-l}$ keeps only $l = r$ and $l = r - 1$, so $(\mathbf{c} * \mathbf{d})_r = 2c_r + c_{r-1}$:

$$\mathbf{c} * \mathbf{d} = (2 + 0,\ 4 + 1,\ 6 + 2,\ 0 + 3) = (2, 5, 8, 3).$$

Hence $pq = 2+5x+8x^2+3x^3$, which one checks by expanding: $(1+2x+3x^2)(2+x) = 2 + x + 4x + 2x^2 + 6x^2 + 3x^3$.

(c) Length 3 holds p and q but not the four coefficients of pq, and although 3 is not a power of two it shows the wrap plainly: with $\mathbf{c} = (1, 2, 3)$, $\mathbf{d} = (2, 1, 0)$ and subscripts modulo 3,

$$\mathbf{c} * \mathbf{d} = (2 + 3,\ 4 + 1,\ 6 + 2) = (5, 5, 8),$$

which is pq with the coefficient 3 of x^3 added onto the constant term, since $x^3 \equiv 1$ modulo $x^3 - 1$. The requirement $n \geq 2d + 1$ in Corollary 23.12.3 is exactly what rules this out.

23.12.5.3 C. Going deeper

Exercise C1: Splitting into three.

Let $n = 3m$ with $m \geq 1$, let $\omega_n = e^{2\pi i/n}$, and for $s = 0, 1, 2$ let

$$\mathbf{u}^{(s)} := \mathbf{W}_m\big(x_s,\ x_{3+s},\ \ldots,\ x_{3(m-1)+s}\big) \in \mathbb{C}^m.$$

(a) Prove that for $0 \leq q \leq 2$ and $0 \leq i \leq m - 1$,

$$(\mathbf{W}_n \mathbf{x})_{qm+i} = \sum_{s=0}^{2} \omega_3^{qs}\, \omega_n^{is}\, u_i^{(s)},$$

where $\omega_3 = e^{2\pi i/3}$.

(b) Deduce a recursive procedure for $n = 3^p$, and show that its cost C_3 satisfies $C_3(3m) \leq 3C_3(m) + 12m$ and hence $C_3(3^p) \leq 4p\,3^p = 4n \log_3 n$.

Hint for (a): imitate the proof of Theorem 23.12.1, splitting the index k by its remainder modulo 3 and using $\omega_n^3 = \omega_m$ and $\omega_n^m = \omega_3$.

Solution.

(a) Write $k = 3t+s$ with $0 \leq s \leq 2$ and $0 \leq t \leq m-1$, which lists each $k \in \{0, \ldots, n-1\}$

exactly once. Then, using $\omega_n^3 = e^{6\pi i/n} = e^{2\pi i/m} = \omega_m$,

$$(\mathbf{W}_n \mathbf{x})_j = \sum_{s=0}^{2} \sum_{t=0}^{m-1} \omega_n^{j(3t+s)} x_{3t+s} = \sum_{s=0}^{2} \omega_n^{js} \sum_{t=0}^{m-1} \omega_m^{jt} x_{3t+s}.$$

Put $j = qm + i$. Since $\omega_m^m = 1$, we get $\omega_m^{jt} = \omega_m^{it}$, so the inner sum is $u_i^{(s)}$ by Definition 23.12.1. And $\omega_n^m = e^{2\pi i m/n} = e^{2\pi i/3} = \omega_3$, so

$$\omega_n^{js} = \omega_n^{(qm+i)s} = \left(\omega_n^m\right)^{qs} \omega_n^{is} = \omega_3^{qs}\, \omega_n^{is}.$$

Substituting gives the stated formula.

(b) The procedure is: split $\mathbf{x}$ by the remainder of the index modulo 3 (no arithmetic); transform the three parts recursively, getting $\mathbf{u}^{(0)}, \mathbf{u}^{(1)}, \mathbf{u}^{(2)}$; multiply $u_i^{(s)}$ by ω_n^{is} for $s = 1, 2$ and all i; and for each i apply $\mathbf{W}_3$ to the resulting triple, placing the three outputs at positions i, $m + i$ and $2m + i$. Correctness is (a).

Cost. The recursive calls cost $3C_3(m)$. The twiddles are $2m$ multiplications, the factors for $s = 0$ being 1. Each three-point transform $(a, b, c) \mapsto (a + b + c,\ a + \omega_3 b + \omega_3^2 c,\ a + \omega_3^2 b + \omega_3 c)$ costs at most 4 multiplications and 6 additions, that is 10 operations, and there are m of them. Hence $C_3(3m) \le 3C_3(m) + 2m + 10m = 3C_3(m) + 12m$.

Now put $D_p = C_3(3^p)/3^p$. The inequality with $m = 3^{p-1}$ reads $3^p D_p \le 3 \cdot 3^{p-1} D_{p-1} + 12 \cdot 3^{p-1}$, that is $D_p \le D_{p-1} + 4$. Since $D_0 = C_3(1) = 0$, induction gives $D_p \le 4p$, so $C_3(3^p) \le 4p\, 3^p$. With $n = 3^p$, that is $4n \log_3 n = O(n \log n)$.

Exercise C2: The fourth power of the transform.

Let $n \ge 1$ and let $\mathbf{R}_n \in M_n(\mathbb{C})$ be the permutation matrix with $(\mathbf{R}_n)_{jl} = 1$ when $j + l \equiv 0 \pmod n$ and 0 otherwise, so that $(\mathbf{R}_n \mathbf{x})_j = x_{n-j}$ with the subscript read modulo n.

(a) Prove that $\mathbf{W}_n^2 = n\, \mathbf{R}_n$.

(b) Deduce that $\mathbf{W}_n^4 = n^2 \mathbf{I}_n$ and $\mathbf{F}_n^4 = \mathbf{I}_n$, and that every eigenvalue of $\mathbf{F}_n$ lies in $\{1, i, -1, -i\}$.

(c) Deduce a second proof that $\mathbf{W}_n^{-1} = \frac{1}{n} \overline{\mathbf{W}_n}$.

Solution.

(a) By Definition 23.12.1 and the definition of the matrix product,

$$(\mathbf{W}_n^2)_{jl} = \sum_{k=0}^{n-1} \omega_n^{jk}\, \omega_n^{kl} = \sum_{k=0}^{n-1} \left(\omega_n^{j+l}\right)^k.$$

Put $z = \omega_n^{j+l}$, so $z^n = 1$. If n divides $j + l$, then $z = 1$ and the sum is n. Otherwise $z \ne 1$ by Example (Roots of Unity), and the geometric-series identity $(z - 1)(1 + z + \cdots + z^{n-1}) = z^n - 1 = 0$ used in the proof of Theorem 11.9.3 gives $\sum_k z^k = 0$, since $z - 1 \ne 0$. So $(\mathbf{W}_n^2)_{jl} = n$ exactly when $j + l \equiv 0 \pmod n$ and 0 otherwise, which is $n\mathbf{R}_n$.

(b) The map $j \mapsto -j$ modulo n is its own inverse, so $\mathbf{R}_n^2 = \mathbf{I}_n$ and $\mathbf{W}_n^4 = (n\mathbf{R}_n)^2 =$

$n^2\mathbf{I}_n$. Since $\mathbf{W}_n = \sqrt{n}\,\mathbf{F}_n$, we get $n^2\mathbf{F}_n^4 = n^2\mathbf{I}_n$, so $\mathbf{F}_n^4 = \mathbf{I}_n$. Hence $x^4 - 1$ annihilates $\mathbf{F}_n$; if $\mathbf{F}_n\mathbf{v} = \lambda\mathbf{v}$ with $\mathbf{v} \neq \mathbf{0}$, then $\mathbf{v} = \mathbf{F}_n^4\mathbf{v} = \lambda^4\mathbf{v}$, so $\lambda^4 = 1$ and $\lambda \in \{1, i, -1, -i\}$ by Example (Roots of Unity).

(c) From (a), $\mathbf{W}_n \cdot \frac{1}{n}\mathbf{W}_n\mathbf{R}_n = \mathbf{R}_n\mathbf{R}_n = \mathbf{I}_n$, so $\mathbf{W}_n^{-1} = \frac{1}{n}\mathbf{W}_n\mathbf{R}_n$. Its (j,l)-entry is $\frac{1}{n}$ times entry $(j, n-l)$ of $\mathbf{W}_n$, namely $\frac{1}{n}\omega_n^{j(n-l)} = \frac{1}{n}\omega_n^{-jl} = \frac{1}{n}\overline{\omega_n^{jl}}$, using $\omega_n^n = 1$ and $|\omega_n| = 1$. That is the (j,l)-entry of $\frac{1}{n}\overline{\mathbf{W}_n}$.

23.13 Fast Matrix Multiplication

Every algorithm in this chapter is built out of matrix products, and every cost we have counted has been counted against them. Section 12 broke one such count: the Fourier matrix is applied in about $n \log n$ operations, although the definition of a matrix–vector product asks for n^2. The definition of a matrix product asks for n^3 multiplications. This section asks whether n^3 is necessary, answers no, and then asks what the answer costs in accuracy.

23.13.1 What a fast algorithm would be

Count the operations that Definition 0.9.9 prescribes. The product $\mathbf{AB}$ of two matrices in $M_n(F)$ has n^2 entries, each of them a sum of n products, so the recipe performs n^3 multiplications and $n^2(n-1)$ additions:

$$n^3 + n^2(n-1) = 2n^3 - n^2$$

arithmetic operations in all. Chapter 2 §06 made the same kind of count for an LU factorization and got $\frac{2}{3}n^3$, so a product costs about three times a factorization. Nothing so far has suggested that either number could be smaller.

Before asking whether it can be, we need to say what "it" is. A claim that some procedure multiplies matrices in fewer than n^3 multiplications is empty until the permitted procedures are fixed, and the fixing has to be done carefully: a procedure allowed to compare two numbers, or to branch on whether an entry is zero, is a different object from one that only computes.

A program is a list of arithmetic instructions, each using the inputs or earlier results, and its cost is the length of the list.

Definition 23.13.1 — Arithmetic cost of a matrix product

Fix a field F and $n \geq 1$, and treat the $2n^2$ entries of $\mathbf{A}, \mathbf{B} \in M_n(F)$ as **indeterminates**. A **straight-line program** is a finite list $g_1, \dots, g_N$ in which each g_t is either

(i) one of the $2n^2$ indeterminates, or a constant of F (an **input step**), or

(ii) $g_r + g_s$, $g_r - g_s$ or $g_r g_s$ for some $r, s < t$ (an **arithmetic step**).

Each g_t is then a polynomial in the indeterminates. The program **computes the product** if for every i, j the polynomial $\sum_k a_{ik}b_{kj}$ occurs among the g_t. Its **cost** is the number of arithmetic steps, and

$$M(n) := \min\{\text{ cost of a program computing the } n \times n \text{ product }\}$$

is the **arithmetic cost** of the $n \times n$ product over F.

In words: input steps are free, because they only name the data; the three arithmetic operations each cost 1; and the program must produce all n^2 entries as **polynomial identities**, not merely for the particular numbers at hand. There are no comparisons, no branches and no loops — a straight-line program does the same thing whatever the data are. Division is excluded, which costs nothing here: none of the algorithms below uses it.

Two examples fix the definition. For $n = 1$ the single instruction $g_3 = g_1 g_2$ computes $a_{11}b_{11}$, so $M(1) = 1$. For $n = 2$ the recipe of Definition 0.9.9 is the program that forms the eight products $a_{ik}b_{kj}$ and then four sums, at a cost of 12; so $M(2) \le 12$. A degenerate case worth naming: a program that lists only input steps has cost 0 and computes nothing, since no entry of **AB** is an indeterminate.

The exponent of matrix multiplication is the smallest growth rate a family of such programs can have.

Definition 23.13.2 — The exponent of matrix multiplication

The **exponent of matrix multiplication** over F is

$$\omega := \inf\{\, \tau \in \mathbb{R} : M(n) = O(n^\tau) \text{ as } n \to \infty \,\}.$$

The infimum is over **all** real τ for which some constant c and some n_0 give $M(n) \le cn^\tau$ for every $n \ge n_0$, so ω is a property of the whole family of problems, not of any one algorithm. The set is non-empty, since $\tau = 3$ belongs to it by the count above. It is bounded below, and the reason is the only thing about ω that this book proves.

Proposition 23.13.1 — The exponent is at least two

$M(n) \ge n^2$ for every $n \ge 1$, and therefore $\omega \ge 2$.

Proof. Let $g_1, \dots, g_N$ be a program computing the $n \times n$ product, and fix i, j. The polynomial $\sum_k a_{ik}b_{kj}$ occurs as some g_t. It is not a constant and not an indeterminate, since it is a non-zero sum of degree-two monomials; so g_t is an arithmetic step. Distinct pairs (i, j) give distinct polynomials, because $\sum_k a_{ik}b_{kj}$ determines i and j from the indices appearing in it. Hence the n^2 pairs require n^2 distinct arithmetic steps, and the cost is at least n^2.

Now let τ be admissible, say $M(n) \le cn^\tau$ for all $n \ge n_0$. Then $n^2 \le cn^\tau$, so $n^{2-\tau} \le c$, for all $n \ge n_0$. If $\tau < 2$ the left side is unbounded, which is impossible; so $\tau \ge 2$. Every admissible τ is at least 2, and hence so is their infimum.

■

So $2 \le \omega \le 3$, and the question of the section is where in that interval ω lies.

Warning. **The exponent is an asymptotic statement and says nothing about any particular size.** $M(n) = O(n^\tau)$ hides a constant, and a program family with a small exponent may carry a constant so large that it loses to the $2n^3 - n^2$ recipe at every size anyone computes with. Section 12's $n \log n$ transform is the exception rather than

the rule: there the constant is small. Below, every claim about a *size* is made with the exact operation count in hand, never from an exponent.

23.13.2 Seven products instead of eight

The classical program for $n = 2$ forms the eight products $a_{ik}b_{kj}$. Its cost is what makes the general recipe cost n^3, because a 2×2 block form turns one product of size n into eight of size $n/2$ — and $8 = 2^3$ is exactly the recursion that reproduces n^3. Reducing eight to seven would change the exponent.

Theorem 23.13.2 — Strassen's identity

Let F be a field, let $m \geq 1$, and let $\mathbf{A}, \mathbf{B} \in M_{2m}(F)$ be partitioned into $m \times m$ blocks,

$$\mathbf{A} = \begin{pmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} \mathbf{B}_{11} & \mathbf{B}_{12} \\ \mathbf{B}_{21} & \mathbf{B}_{22} \end{pmatrix}.$$

Define seven products

$$\begin{aligned} \mathbf{P}_1 &= (\mathbf{A}_{11} + \mathbf{A}_{22})(\mathbf{B}_{11} + \mathbf{B}_{22}), & \mathbf{P}_2 &= (\mathbf{A}_{21} + \mathbf{A}_{22})\mathbf{B}_{11}, \\ \mathbf{P}_3 &= \mathbf{A}_{11}(\mathbf{B}_{12} - \mathbf{B}_{22}), & \mathbf{P}_4 &= \mathbf{A}_{22}(\mathbf{B}_{21} - \mathbf{B}_{11}), \\ \mathbf{P}_5 &= (\mathbf{A}_{11} + \mathbf{A}_{12})\mathbf{B}_{22}, & \mathbf{P}_6 &= (\mathbf{A}_{21} - \mathbf{A}_{11})(\mathbf{B}_{11} + \mathbf{B}_{12}), \\ \mathbf{P}_7 &= (\mathbf{A}_{12} - \mathbf{A}_{22})(\mathbf{B}_{21} + \mathbf{B}_{22}). \end{aligned}$$

Then, with the same block partition of $\mathbf{AB}$,

$$\mathbf{AB} = \begin{pmatrix} \mathbf{P}_1 + \mathbf{P}_4 - \mathbf{P}_5 + \mathbf{P}_7 & \mathbf{P}_3 + \mathbf{P}_5 \\ \mathbf{P}_2 + \mathbf{P}_4 & \mathbf{P}_1 + \mathbf{P}_3 - \mathbf{P}_2 + \mathbf{P}_6 \end{pmatrix}.$$

Only seven products of $m \times m$ matrices occur on the right, where Theorem 7.1.1 asks for eight.

Idea. There is no derivation to reproduce: the seven products were found by Strassen, and what a proof can do is check them. What deserves watching during the check is *which* rules it uses. Every step expands a product of sums by distributivity and then cancels equal terms. No two blocks are ever interchanged, and no block is ever inverted or divided by — only the ring operations of $M_m(F)$ appear. That is the whole point, because blocks do not commute.

Proof. Expand the seven products by distributivity, keeping every factor in its place:

$$\begin{aligned} \mathbf{P}_1 &= \mathbf{A}_{11}\mathbf{B}_{11} + \mathbf{A}_{11}\mathbf{B}_{22} + \mathbf{A}_{22}\mathbf{B}_{11} + \mathbf{A}_{22}\mathbf{B}_{22}, \\ \mathbf{P}_2 &= \mathbf{A}_{21}\mathbf{B}_{11} + \mathbf{A}_{22}\mathbf{B}_{11}, \\ \mathbf{P}_3 &= \mathbf{A}_{11}\mathbf{B}_{12} - \mathbf{A}_{11}\mathbf{B}_{22}, \\ \mathbf{P}_4 &= \mathbf{A}_{22}\mathbf{B}_{21} - \mathbf{A}_{22}\mathbf{B}_{11}, \\ \mathbf{P}_5 &= \mathbf{A}_{11}\mathbf{B}_{22} + \mathbf{A}_{12}\mathbf{B}_{22}, \\ \mathbf{P}_6 &= \mathbf{A}_{21}\mathbf{B}_{11} + \mathbf{A}_{21}\mathbf{B}_{12} - \mathbf{A}_{11}\mathbf{B}_{11} - \mathbf{A}_{11}\mathbf{B}_{12}, \\ \mathbf{P}_7 &= \mathbf{A}_{12}\mathbf{B}_{21} + \mathbf{A}_{12}\mathbf{B}_{22} - \mathbf{A}_{22}\mathbf{B}_{21} - \mathbf{A}_{22}\mathbf{B}_{22}. \end{aligned}$$

Take the four combinations in turn. For the $(1,1)$ block,

$$\begin{aligned}\mathbf{P}_1+\mathbf{P}_4-\mathbf{P}_5+\mathbf{P}_7 &= \mathbf{A}_{11}\mathbf{B}_{11}+\mathbf{A}_{11}\mathbf{B}_{22}+\mathbf{A}_{22}\mathbf{B}_{11}+\mathbf{A}_{22}\mathbf{B}_{22}\\ &\quad+\mathbf{A}_{22}\mathbf{B}_{21}-\mathbf{A}_{22}\mathbf{B}_{11}\\ &\quad-\mathbf{A}_{11}\mathbf{B}_{22}-\mathbf{A}_{12}\mathbf{B}_{22}\\ &\quad+\mathbf{A}_{12}\mathbf{B}_{21}+\mathbf{A}_{12}\mathbf{B}_{22}-\mathbf{A}_{22}\mathbf{B}_{21}-\mathbf{A}_{22}\mathbf{B}_{22}\\ &= \mathbf{A}_{11}\mathbf{B}_{11}+\mathbf{A}_{12}\mathbf{B}_{21},\end{aligned}$$

since $\mathbf{A}_{11}\mathbf{B}_{22}$, $\mathbf{A}_{22}\mathbf{B}_{11}$, $\mathbf{A}_{22}\mathbf{B}_{22}$, $\mathbf{A}_{22}\mathbf{B}_{21}$ and $\mathbf{A}_{12}\mathbf{B}_{22}$ each occur once with each sign. For the $(1,2)$ block,

$$\mathbf{P}_3+\mathbf{P}_5=\mathbf{A}_{11}\mathbf{B}_{12}-\mathbf{A}_{11}\mathbf{B}_{22}+\mathbf{A}_{11}\mathbf{B}_{22}+\mathbf{A}_{12}\mathbf{B}_{22}=\mathbf{A}_{11}\mathbf{B}_{12}+\mathbf{A}_{12}\mathbf{B}_{22}.$$

For the $(2,1)$ block,

$$\mathbf{P}_2+\mathbf{P}_4=\mathbf{A}_{21}\mathbf{B}_{11}+\mathbf{A}_{22}\mathbf{B}_{11}+\mathbf{A}_{22}\mathbf{B}_{21}-\mathbf{A}_{22}\mathbf{B}_{11}=\mathbf{A}_{21}\mathbf{B}_{11}+\mathbf{A}_{22}\mathbf{B}_{21}.$$

For the $(2,2)$ block,

$$\begin{aligned}\mathbf{P}_1+\mathbf{P}_3-\mathbf{P}_2+\mathbf{P}_6 &= \mathbf{A}_{11}\mathbf{B}_{11}+\mathbf{A}_{11}\mathbf{B}_{22}+\mathbf{A}_{22}\mathbf{B}_{11}+\mathbf{A}_{22}\mathbf{B}_{22}\\ &\quad+\mathbf{A}_{11}\mathbf{B}_{12}-\mathbf{A}_{11}\mathbf{B}_{22}\\ &\quad-\mathbf{A}_{21}\mathbf{B}_{11}-\mathbf{A}_{22}\mathbf{B}_{11}\\ &\quad+\mathbf{A}_{21}\mathbf{B}_{11}+\mathbf{A}_{21}\mathbf{B}_{12}-\mathbf{A}_{11}\mathbf{B}_{11}-\mathbf{A}_{11}\mathbf{B}_{12}\\ &= \mathbf{A}_{21}\mathbf{B}_{12}+\mathbf{A}_{22}\mathbf{B}_{22}.\end{aligned}$$

The four results are the four blocks of $\mathbf{AB}$ given by Theorem 7.1.1. This proves the identity.

■

Two features of that proof matter more than the result. First, it used only addition, subtraction, multiplication and their laws in $M_m(F)$ — never the commutativity of a product, never an inverse, never a division. So the identity would hold with the blocks taken in any ring whatever. Second, the case $m=1$ is the ordinary 2×2 product with seven scalar multiplications instead of eight, and the case $m>1$ is the same statement one level up. That self-similarity is what the next theorem exploits.

Example. (Seven products on integer data)

Multiply $\mathbf{A}=\begin{pmatrix}1&2\\3&4\end{pmatrix}$ and $\mathbf{B}=\begin{pmatrix}5&6\\7&8\end{pmatrix}$ by Theorem 23.13.2, with blocks of size 1, so that each $\mathbf{P}_k$ is a number. Check against the classical product.

Solution. The seven products are

$$\begin{aligned}\mathbf{P}_1&=(1+4)(5+8)=65, & \mathbf{P}_2&=(3+4)\cdot 5=35,\\ \mathbf{P}_3&=1\cdot(6-8)=-2, & \mathbf{P}_4&=4\cdot(7-5)=8,\\ \mathbf{P}_5&=(1+2)\cdot 8=24, & \mathbf{P}_6&=(3-1)(5+6)=22,\\ \mathbf{P}_7&=(2-4)(7+8)=-30.\end{aligned}$$

Then

$$\mathbf{P}_1 + \mathbf{P}_4 - \mathbf{P}_5 + \mathbf{P}_7 = 65 + 8 - 24 - 30 = 19,$$
$$\mathbf{P}_3 + \mathbf{P}_5 = -2 + 24 = 22,$$
$$\mathbf{P}_2 + \mathbf{P}_4 = 35 + 8 = 43,$$
$$\mathbf{P}_1 + \mathbf{P}_3 - \mathbf{P}_2 + \mathbf{P}_6 = 65 - 2 - 35 + 22 = 50.$$

The classical product is $\begin{pmatrix} 5+14 & 6+16 \\ 15+28 & 18+32 \end{pmatrix} = \begin{pmatrix} 19 & 22 \\ 43 & 50 \end{pmatrix}$, the same.

Warning. **The seven products are not seven of the eight classical ones.** Not one of $\mathbf{P}_1, \dots, \mathbf{P}_7$ equals a product $a_{ik}b_{kj}$; each is a product of two *combinations*. Dropping a classical product and repairing the rest is impossible, and the identity gives no license to do arithmetic in a different order in any other formula. What it gives is one algebraic fact about one bilinear map, and everything below is that fact applied to itself.

Quick check. Does Theorem 23.13.2 still hold over $\mathbb{F}_2$, where $1 + 1 = 0$?

Solution. Yes. The field F was arbitrary, and the proof used only distributivity, associativity and the cancellation of a term against its negative. What changes over $\mathbb{F}_2$ is only cosmetic: every minus sign may be written as a plus sign, since $-x = x$ there.

23.13.3 The recursion, and its exact cost

Apply Theorem 23.13.2 with $m \times m$ blocks, and each of the seven products is a product of two $m \times m$ matrices, to be computed by the same rule. The recursion bottoms out at 1×1 blocks, where a product is one multiplication.

Theorem 23.13.3 — The cost of the recursion

Let $n = 2^p$ with $p \geq 0$. Applying Theorem 23.13.2 recursively, with the 1×1 case done by a single multiplication, multiplies two matrices in $M_n(F)$ with exactly

$$T(n) = 7n^{\log_2 7} - 6n^2$$

arithmetic operations. In particular $T(n) = O(n^{\log_2 7})$ and $\omega \leq \log_2 7 = 2.8073\ldots$.

Idea. Two counts and one recurrence. Count the block additions in Theorem 23.13.2: ten to build the operands of the seven products, eight to assemble the four blocks of the answer, eighteen in all, each of them $(n/2)^2$ scalar additions. That gives $T(n) = 7T(n/2) + \frac{9}{2}n^2$. Then solve the recurrence exactly, by induction on p rather than by a growth estimate, so that the constants are visible.

Proof. **Step 1: the recurrence.** Let $n = 2m$ with $m \geq 1$, and partition $\mathbf{A}$ and $\mathbf{B}$ into four $m \times m$ blocks each. Forming the operands of $\mathbf{P}_1, \dots, \mathbf{P}_7$ uses the block sums $\mathbf{A}_{11}+\mathbf{A}_{22}$, $\mathbf{B}_{11}+\mathbf{B}_{22}$, $\mathbf{A}_{21}+\mathbf{A}_{22}$, $\mathbf{B}_{12}-\mathbf{B}_{22}$, $\mathbf{B}_{21}-\mathbf{B}_{11}$, $\mathbf{A}_{11}+\mathbf{A}_{12}$, $\mathbf{A}_{21}-\mathbf{A}_{11}$, $\mathbf{B}_{11}+\mathbf{B}_{12}$, $\mathbf{A}_{12}-\mathbf{A}_{22}$ and $\mathbf{B}_{21}+\mathbf{B}_{22}$: ten of them. Assembling the answer uses three block additions for the $(1,1)$ block, one for $(1,2)$, one for $(2,1)$ and three for $(2,2)$: eight more. Each

block addition is m^2 scalar additions, and the seven products cost $T(m)$ each. Hence

$$T(2m) = 7\,T(m) + 18m^2, \qquad T(1) = 1.$$

Step 2: the solution. We show $T(2^p) = 7 \cdot 7^p - 6 \cdot 4^p$ by induction on p. For $p = 0$ the right side is $7 - 6 = 1 = T(1)$. Suppose it holds for p. Taking $m = 2^p$, so that $m^2 = 4^p$,

$$\begin{aligned} T(2^{p+1}) &= 7\big(7 \cdot 7^p - 6 \cdot 4^p\big) + 18 \cdot 4^p \\ &= 7 \cdot 7^{p+1} - 42 \cdot 4^p + 18 \cdot 4^p \\ &= 7 \cdot 7^{p+1} - 24 \cdot 4^p = 7 \cdot 7^{p+1} - 6 \cdot 4^{p+1}, \end{aligned}$$

which is the statement for $p + 1$.

Step 3: reading it in n. With $n = 2^p$ we have $4^p = n^2$, and $7^p = 2^{p \log_2 7} = n^{\log_2 7}$. So $T(n) = 7n^{\log_2 7} - 6n^2$, which is at most $7n^{\log_2 7}$.

Finally, the recursion is a straight-line program in the sense of Definition 23.13.1: it uses only additions, subtractions and multiplications, and by Theorem 23.13.2 it produces every entry of $\mathbf{AB}$ as a polynomial identity. Hence $M(n) \le 7n^{\log_2 7}$ along the powers of two. For general n, pad $\mathbf{A}$ and $\mathbf{B}$ with zero rows and columns to the next power of two, which at most doubles n; the product of the padded matrices has $\mathbf{AB}$ in its leading block, so $M(n) \le 7(2n)^{\log_2 7} < 49\, n^{\log_2 7}$ for every n. Therefore $\tau = \log_2 7$ is admissible in Definition 23.13.2, and $\omega \le \log_2 7$.

■

The number $\log_2 7 = 2.8073\ldots$ is below 3, and that is the whole content: an operation that looked like an n^3 operation is not one. The mechanism is worth naming, because Section 12 used it too. There, the Fourier matrix $\mathbf{F}_n$ was *factored* into a permutation, two copies of $\mathbf{F}_{n/2}$ and a diagonal factor, and the recurrence $C(n) = 2C(n/2) + O(n)$ followed. Here the bilinear map $(\mathbf{A}, \mathbf{B}) \mapsto \mathbf{AB}$ is factored into seven products and eighteen sums, and the recurrence $T(n) = 7T(n/2) + \frac{9}{2}n^2$ follows. In both cases the saving comes from a factorization, and the exponent is decided by the *number of recursive calls* against the *size reduction*: 2 calls at half size against a linear overhead gives $n \log n$; 7 calls at half size against a quadratic overhead gives $n^{\log_2 7}$.

Remark. The recursion is not a way to make $M(2)$ smaller than 12. Its own count at $n = 2$ is $T(2) = 49 - 24 = 25$: seven multiplications but eighteen additions, against eight and four. What it does is trade one multiplication for fourteen additions at *every* level, and the trade pays only because the multiplications are what recurse.

23.13.4 What is known about the exponent, and what is not

Theorem 23.13.3 gives $\omega \le \log_2 7 < 2.8074$, and Proposition 23.13.1 gives $\omega \ge 2$. Both are proved above. The rest of this subsection is **stated and not proved here**, and nothing in this book depends on any of it.

Strassen's bound was the first below 3, and it has been improved many times since. The decisive technique is the *laser method* of Coppersmith and Winograd, which brought the bound below

2.376; successive refinements of that method by several authors have since pushed the published bound below 2.372. No lower bound better than the $\omega \geq 2$ proved above is known. **Whether $\omega = 2$ is an open problem.**

Two honest caveats belong with those numbers.

- The bounds below $\log_2 7$ are obtained by analyzing families of recursive constructions, not by exhibiting seven-product identities; the algorithms they yield carry constants so large that at every size that arises in practice they are slower than the $2n^3 - n^2$ recipe. This is a known feature of the constructions, and it is recorded here, not proved.
- ω may depend on the field F, and the definition above was made field by field for that reason. The bounds just quoted, and Strassen's, hold over every field.

Remark. The name **bilinear complexity** belongs to a related quantity: the least number of *multiplications* (as opposed to all arithmetic operations) needed to compute a bilinear map, which for the 2×2 product is exactly 7. The lower bound 7 is a theorem of Winograd and is not proved here; Theorem 23.13.2 is the upper half of it. The exponent ω is the same whether it is defined through Definition 23.13.1 or through multiplications alone, which is also not proved here and is not used.

23.13.5 Accuracy: a norm bound, but not an entrywise one

Everything so far was exact algebra. In the floating-point model of Definition 23.1.1 the two algorithms are not interchangeable, and the difference is sharper than "one is less accurate".

Start with the classical recipe, which inherits Section 1's analysis directly. Write $|\mathbf{A}|$ for the entrywise absolute value ($|a_{ij}|$), as in Chapter 18, and $\widehat{\mathbf{C}}$ for the computed product. Everything below is real, because Definition 23.1.1 is.

Proposition 23.13.4 — The classical product has a small entrywise error

Let $\mathbf{A}, \mathbf{B} \in M_n(\mathbb{R})$ have representable entries, let $nu < 1$, and let $\widehat{\mathbf{C}}$ be the product computed by Definition 0.9.9, each entry as one inner product taken in the natural order. Then

$$\left|\widehat{\mathbf{C}} - \mathbf{AB}\right| \;\leq\; \gamma_n |\mathbf{A}||\mathbf{B}|$$

entrywise.

Proof. Fix i and j, and let $\mathbf{x}$ be row i of $\mathbf{A}$ and $\mathbf{y}$ column j of $\mathbf{B}$, both with representable entries. By Definition 0.9.9, $(\mathbf{AB})_{ij} = \mathbf{x}^{\top}\mathbf{y}$, and $\widehat{c}_{ij}$ is exactly the quantity s_n of Theorem 23.1.2. That theorem, applicable since $nu < 1$, gives a $\Delta\mathbf{x}$ with $\widehat{c}_{ij} = (\mathbf{x} + \Delta\mathbf{x})^{\top}\mathbf{y}$ and $|\Delta x_k| \leq \gamma_n |x_k|$ for every k. Hence

$$\left|\widehat{c}_{ij} - (\mathbf{AB})_{ij}\right| = \left|\sum_k \Delta x_k \, y_k\right| \leq \sum_k |\Delta x_k| \, |y_k| \leq \gamma_n \sum_k |a_{ik}| \, |b_{kj}|,$$

where the first inequality is the triangle inequality and the second substitutes the bound on $\Delta\mathbf{x}$ together with $|x_k| = |a_{ik}|$. The right side is $\gamma_n(|\mathbf{A}||\mathbf{B}|)_{ij}$. Since i and j were

arbitrary, this proves the bound.

■

The bound is **entrywise**, and that is its strength: the error in the (i, j) entry is measured against the size of the data that produced *that* entry. If $(|\mathbf{A}||\mathbf{B}|)_{ij}$ is tiny, the error there is tiny too. In particular, if $\mathbf{A}$ and $\mathbf{B}$ have non-negative entries, then $(|\mathbf{A}||\mathbf{B}|)_{ij} = (\mathbf{AB})_{ij}$ and every entry is computed with small *relative* error.

Strassen's algorithm satisfies a weaker bound, in which the whole of $\mathbf{A}$ and the whole of $\mathbf{B}$ appear on the right. Here is the base case, proved.

Proposition 23.13.5 — Strassen's two-by-two product satisfies a norm bound

Let $\mathbf{A}, \mathbf{B} \in M_2(\mathbb{R})$ have representable entries, put $\alpha = \max_{i,j}|a_{ij}|$ and $\beta = \max_{i,j}|b_{ij}|$, and let $\widehat{\mathbf{C}}$ be the result of evaluating Theorem 23.13.2 with $m = 1$, each $\mathbf{P}_k$ as written and each of the four combinations left to right. If $6u < 1$, then

$$\max_{i,j}\left|\widehat{c}_{ij} - (\mathbf{AB})_{ij}\right| \;\le\; 12\,\gamma_6\,\alpha\beta.$$

Idea. Each $\mathbf{P}_k$ is built by at most three operations, so the computed $\widehat{\mathbf{P}}_k$ carries at most three factors $1 + \delta$. Each output block is a sum of at most four of them, formed by at most three further additions, so each summand carries at most three more. Six factors in all, which is γ_6 by Lemma 23.1.1. The only other ingredient is a crude size bound on each $\mathbf{P}_k$.

Proof. **Sizes.** Each factor of $\mathbf{P}_k$ is either a single entry or a sum of two, so $|\mathbf{P}_1|, |\mathbf{P}_6|, |\mathbf{P}_7| \le (2\alpha)(2\beta) = 4\alpha\beta$, while $\mathbf{P}_2, \mathbf{P}_3, \mathbf{P}_4, \mathbf{P}_5$ each have a single entry as one factor and so satisfy $|\mathbf{P}_k| \le 2\alpha\beta$.

Rounding. Fix k. Forming $\mathbf{P}_k$ takes at most one addition on each side and then one multiplication: at most three operations, each contributing a factor $1 + \delta$ with $|\delta| \le u$ by Definition 23.1.1. So $\widehat{\mathbf{P}}_k$ is $\mathbf{P}_k$ times a product of at most three such factors.

Assembly. Take $\widehat{c}_{11}$, computed as $((\widehat{\mathbf{P}}_1 + \widehat{\mathbf{P}}_4) - \widehat{\mathbf{P}}_5) + \widehat{\mathbf{P}}_7$. Each of the three additions contributes one factor $1 + \delta$ to every summand already accumulated, so $\widehat{\mathbf{P}}_1$ and $\widehat{\mathbf{P}}_4$ pick up three such factors, $\widehat{\mathbf{P}}_5$ two and $\widehat{\mathbf{P}}_7$ one. Combining with the previous paragraph, each $\mathbf{P}_m$ is multiplied by a product of at most six factors $1 + \delta$, which by Lemma 23.1.1 is $1 + \psi_m$ with $|\psi_m| \le \gamma_6$, legitimate because $6u < 1$. Hence

$$\widehat{c}_{11} = \sum_{m \in \{1,4,5,7\}} \pm\,\mathbf{P}_m(1 + \psi_m),$$

with the signs of Theorem 23.13.2. Subtracting $c_{11} = \mathbf{P}_1 + \mathbf{P}_4 - \mathbf{P}_5 + \mathbf{P}_7$ and using the triangle inequality,

$$|\widehat{c}_{11} - c_{11}| \;\le\; \gamma_6 \sum_{m \in \{1,4,5,7\}} |\mathbf{P}_m| \;\le\; \gamma_6\,(4 + 2 + 2 + 4)\alpha\beta = 12\gamma_6\alpha\beta.$$

The same argument gives $|\widehat{c}_{22} - c_{22}| \le \gamma_6(4 + 2 + 2 + 4)\alpha\beta = 12\gamma_6\alpha\beta$ for the sum

$\mathbf{P}_1 + \mathbf{P}_3 - \mathbf{P}_2 + \mathbf{P}_6$. The blocks $\widehat{c}_{12} = \widehat{\mathbf{P}}_3 + \widehat{\mathbf{P}}_5$ and $\widehat{c}_{21} = \widehat{\mathbf{P}}_2 + \widehat{\mathbf{P}}_4$ use one addition, so four factors and $\gamma_4 \le \gamma_6$ suffice, and $\sum_m |\mathbf{P}_m| \le 4\alpha\beta$ there. The largest of the four bounds is $12\gamma_6\alpha\beta$, which proves the proposition.

■

A bound of this shape survives the recursion, with a constant that grows with n: for $n = 2^p$ there is a constant $c(n)$, polynomial in n, with

$$\max_{i,j} \left|\widehat{c}_{ij} - (\mathbf{AB})_{ij}\right| \;\le\; c(n)\, u \max_{i,j}|a_{ij}| \max_{i,j}|b_{ij}| + O(u^2).$$

This is not proved here. A bound of this form was first established by Brent, and the constant has been improved since; the induction is longer than this section, and nothing below uses it. What *is* proved below is that no improvement of it can be entrywise.

Theorem 23.13.6 — Strassen's algorithm has no useful entrywise error bound

Work in a model as in Definition 23.1.1, and suppose the set $\mathcal{R}$ of representable numbers contains a number ε with

$$\varepsilon > 0, \qquad 1 + \varepsilon \in \mathcal{R}, \qquad \varepsilon^2 \in \mathcal{R}, \qquad \mathrm{fl}\big((1+\varepsilon)^2\big) = 1 + 2\varepsilon.$$

Put $\mathbf{A} = \mathbf{B} = \mathrm{diag}(1, \varepsilon)$. Then the $\widehat{\mathbf{C}}$ of Proposition 23.13.5 has $\widehat{c}_{22} = 0$, while $(\mathbf{AB})_{22} = \varepsilon^2$. Consequently, any constant c for which

$$\left|\widehat{\mathbf{C}} - \mathbf{AB}\right| \;\le\; c\,u\,|\mathbf{A}||\mathbf{B}|$$

holds entrywise for this $\mathbf{A}$ and $\mathbf{B}$ must satisfy $c \ge 1/u$.

Idea. Choose the data so that the $(2,2)$ entry of the product is as small as the model can see, while the quantity $\mathbf{P}_1$ from which it is assembled has size 1. The term ε^2 is then the last bit of $(1+\varepsilon)^2$, and the fourth hypothesis says the rounding throws exactly that bit away. Nothing later can put it back, because the remaining steps are exact.

Proof. Write $a_{11} = b_{11} = 1$, $a_{22} = b_{22} = \varepsilon$ and $a_{12} = a_{21} = b_{12} = b_{21} = 0$; all are in $\mathcal{R}$, since $0, 1, \varepsilon \in \mathcal{R}$. Note first that fl fixes every element of $\mathcal{R}$, because a nearest element of $\mathcal{R}$ to a member of $\mathcal{R}$ is that member. By Definition 0.9.9, $(\mathbf{AB})_{22} = a_{21}b_{12} + a_{22}b_{22} = \varepsilon^2$.

Compute the four quantities that Theorem 23.13.2 combines into the $(2,2)$ entry. The operand sums are $\mathrm{fl}(a_{11} + a_{22}) = \mathrm{fl}(1+\varepsilon) = 1 + \varepsilon$ and likewise for $\mathbf{B}$, both exact by hypothesis; so

$$\widehat{\mathbf{P}}_1 = \mathrm{fl}\big((1+\varepsilon)(1+\varepsilon)\big) = \mathrm{fl}\big((1+\varepsilon)^2\big) = 1 + 2\varepsilon,$$

by the fourth hypothesis. Next $\widehat{\mathbf{P}}_2 = \mathrm{fl}(\mathrm{fl}(0+\varepsilon)\cdot 1) = \varepsilon$, and $\widehat{\mathbf{P}}_3 = \mathrm{fl}(1 \cdot \mathrm{fl}(0-\varepsilon)) = -\varepsilon$, using $-\mathcal{R} = \mathcal{R}$; and $\widehat{\mathbf{P}}_6 = \mathrm{fl}(\mathrm{fl}(0-1)\cdot\mathrm{fl}(1+0)) = \mathrm{fl}(-1) = -1$. Each of these values lies in $\mathcal{R}$, so each rounding is the identity.

Assemble $\mathbf{P}_1 + \mathbf{P}_3 - \mathbf{P}_2 + \mathbf{P}_6$ left to right. In order,

$$\mathrm{fl}\big((1+2\varepsilon) + (-\varepsilon)\big) = 1 + \varepsilon, \qquad \mathrm{fl}\big((1+\varepsilon) - \varepsilon\big) = 1, \qquad \mathrm{fl}\big(1 + (-1)\big) = 0,$$

every intermediate value being in $\mathcal{R}$ and so fixed by fl. Hence $\widehat{c}_{22} = 0$.

Finally $|\mathbf{A}||\mathbf{B}| = \operatorname{diag}(1, \varepsilon^2)$, so an entrywise bound at the $(2,2)$ position reads $\varepsilon^2 = |0 - \varepsilon^2| \le cu\varepsilon^2$. Dividing by $\varepsilon^2 > 0$ gives $1 \le cu$, that is $c \ge 1/u$. This proves the theorem.

■

The constant $1/u$ is about 10^{16} in the arithmetic in common use, so the conclusion is that no entrywise bound worth stating exists: Proposition 23.13.4 holds with $c = \gamma_2/u$, which is close to 2, and for Strassen's algorithm the same inequality at $n = 2$ needs a constant larger than the reciprocal of the unit roundoff. The hypotheses of the theorem are not exotic.

They are not vacuous either, and the fourth one fixes the scale of ε. Since $1+\varepsilon$ is representable, Definition 23.1.1 writes $\operatorname{fl}\big((1+\varepsilon)^2\big) = (1+\varepsilon)^2(1+\delta)$ with $|\delta| \le u$, and the fourth hypothesis says the left side is $1 + 2\varepsilon$, which forces

$$\delta = -\frac{\varepsilon^2}{(1+\varepsilon)^2}, \qquad \text{hence} \qquad \varepsilon^2 \le u\,(1+\varepsilon)^2.$$

So ε is at most about $\sqrt{u}$: the theorem asks for a quantity small enough that its square falls off the end of the significand, and for nothing else. The next example produces one.

Example. (A small entry lost entirely)

Work in binary arithmetic with 53-bit significands, rounding to nearest, so that $u = 2^{-53}$. Verify the hypotheses of Theorem 23.13.6 for $\varepsilon = 2^{-27}$, and say what each algorithm returns for the $(2,2)$ entry of the product of $\mathbf{A} = \mathbf{B} = \operatorname{diag}(1, 2^{-27})$.

Solution. The hypotheses. A number is representable when its significand fits in 53 bits. Now $\varepsilon = 2^{-27}$ is a power of two, so $\varepsilon \in \mathcal{R}$ and $\varepsilon^2 = 2^{-54} \in \mathcal{R}$. The number $1 + 2^{-27}$ needs bits 0 through 27, that is 28 of them, so it is representable. Finally

$$(1 + 2^{-27})^2 = 1 + 2^{-26} + 2^{-54},$$

which needs 55 bits and is not. In $[1,2)$ the representable numbers are spaced 2^{-52} apart; our value lies 2^{-54} above $1 + 2^{-26}$ and $3 \cdot 2^{-54}$ below the next one up, so rounding to nearest gives $\operatorname{fl}\big((1+2^{-27})^2\big) = 1 + 2^{-26} = 1 + 2\varepsilon$. All four hypotheses hold.

The two answers. By Theorem 23.13.6, Strassen's algorithm returns $\widehat{c}_{22} = 0$, while the true value is 2^{-54}: the relative error is 1, not a loss of digits but a loss of all of them. The classical recipe computes $\operatorname{fl}(0 \cdot 0) = 0$ and then $\operatorname{fl}\big(0 + \operatorname{fl}(2^{-27} \cdot 2^{-27})\big) = \operatorname{fl}(2^{-54}) = 2^{-54}$, the exact answer.

The other three entries of the Strassen product also come out exactly right here, and the error 2^{-54} is invisible when measured against $\max|a_{ij}| \max|b_{ij}| = 1$, which is what Proposition 23.13.5 measures it against. That is the whole contrast in one example.

Warning. **"No entrywise bound" is not "unstable".** Proposition 23.13.5 is a genuine bound, and for a matrix whose entries are all of comparable size it says as much as Proposition 23.13.4 does. The two part company only when the entries of $\mathbf{AB}$ span many orders of magnitude, and then the classical algorithm delivers something Strassen's does not: small relative error in the small entries. Backward stability in the sense of Definition 23.1.3 is likewise not in question — the failure above is a failure of *entrywise* accuracy, exactly as Chapter 15 §08 warned that conditioning and stability

answer different questions.

23.13.6 Whether to use it

The operation count and the error analysis pull in opposite directions, and the honest summary is a list of exact numbers rather than a verdict. Suppose the recursion is stopped at a base size n_0, below which the classical recipe is used, and let $n = n_0 2^p$. The same induction as in Theorem 23.13.3, started from $T(n_0) = 2n_0^3 - n_0^2$, gives

$$T(n_0 2^p) = 7^p\big(2n_0^3 - n_0^2\big) + 6n_0^2\big(7^p - 4^p\big).$$

Three readings of this formula. With $n_0 = 1$ the recursion runs to scalars, and it is *slower* than the classical recipe until n exceeds about 654; at $n = 512$ it costs 280 902 385 operations against 268 173 312, and at $n = 1024$ it costs 1 971 035 287 against 2 146 435 072. With a classical base case the picture changes completely: a *single* level of the recursion, $p = 1$, costs $14n_0^3 + 11n_0^2$ against the classical $16n_0^3 - 4n_0^2$ at size $2n_0$, and the first wins as soon as $2n_0^3 > 15n_0^2$, that is from $n_0 = 8$, so from $n = 16$. And at $n = 1024$ with $n_0 = 64$ the count is 1 301 696 512, about 0.61 of the classical one.

So on operation count alone the trade is favorable at sizes that are not large. Three things keep the classical algorithm the one in ordinary use at small and moderate sizes, and none of them is visible in an operation count.

- **Additions are not free in the way the count assumes.** The seven products must be stored, and the eighteen block sums read and write whole blocks that the classical recipe never touches. An operation count charges 1 for an addition and 1 for a multiplication and charges nothing for moving a number; on a real machine the movement is often the expensive part, and the recursion moves much more data than it saves in arithmetic.
- **The error bound is weaker, and it is weaker in a way that matters exactly when it is not expected** — see Example (A small entry lost entirely).
- **The sizes have to cooperate.** The recursion wants even dimensions at every level; an odd size must be padded or handled specially, and the bookkeeping erodes the saving at precisely the moderate sizes where it is thinnest.

The conclusion is not that Theorem 23.13.2 is a curiosity. It is used, at large sizes, with a classical base case and with the accuracy caveat understood. What it is not is a replacement for a definition: **AB** still means what Definition 0.9.9 says it means, and every theorem in this book about products is untouched. A fast algorithm changes the cost of an operation, never the operation.

23.13.7 Summary and transfer

Chapter 20 closed Part V with a complaint and a promise: "every proof here is an existence or a comparison, and not one of them is an algorithm. That is the subject of Chapter 23." Thirteen sections later, the promise is paid, and what "compute" turned out to mean can be said in one sentence: a computed answer is the exact answer to a nearby question, and how near depends on the algorithm, while how much that nearness costs depends on the problem.

The chapter's one new assumption was the floating-point model of Definition 23.1.1, a description of a machine stated as a definition. Everything else was proved from it and from the linear algebra of Chapters 0 to 20.

- **What a computed answer means.** Section 1 stated the model, proved Lemma 23.1.1 and Theorem 23.1.2, and gave the words the rest of the chapter needs: Definition 23.1.3, Definition 23.1.2 and the rule Theorem 23.1.3, that the forward error is at most the condition number times the backward error.
- **Solving a system.** Section 2 read elimination as a sequence of Schur complements (Theorem 23.2.1), counted it (Proposition 23.2.3), and proved backward error analyses in the cases it could reach: Theorem 23.2.5 outright, and Theorem 23.2.6 for the ordering it displays, the same bound for Chapter 2's ordering being stated with credit. With it came the growth factor Definition 23.2.1, the bound Theorem 23.2.8 — attained, by Example (A matrix that really grows) — and the pivot-free safety of Cholesky (Theorem 23.2.9).
- **Least squares.** Section 3 proved that the sensitivity of the least-squares solution involves the residual as well as $\kappa_2(\mathbf{A})$ (Theorem 23.3.1), that the normal equations lose twice the digits (Theorem 23.3.2), and that a reflection does not (Theorem 23.3.3) — that last for one reflection applied to a matrix, the accumulation over the whole factorization being stated with credit.
- **Eigenvalues.** Section 4 built the power method (Theorem 23.4.1), inverse iteration (Theorem 23.4.3) and Rayleigh quotient iteration (Theorem 23.4.4); Section 5 identified the QR algorithm with orthogonal iteration (Theorem 23.5.2), proved its convergence (Theorem 23.5.3), and explained the Hessenberg reduction (Proposition 23.5.4) and the shifts.
- **Iterating in a subspace.** Section 6 built the Krylov space (Definition 23.6.1), the Arnoldi process (Theorem 23.6.2) and its Hermitian three-term form (Theorem 23.6.3), and showed that the Ritz values (Definition 23.6.2) interlace (Theorem 23.6.4) and carry Chapter 19's residual bounds. Section 7 minimized over the same space: Theorem 23.7.4, the Chebyshev bound Lemma 23.7.6, and the square root in Theorem 23.7.7.
- **One piece of pure mathematics.** Section 8 showed that an algorithm and a differential equation can be the same object: the Lax pair Definition 23.8.1, the isospectral theorem Theorem 23.8.1, and the Toda flow's relation to the QR algorithm (Theorem 23.8.5).
- **Applications.** Section 9 turned a mass-and-spring system into a generalized eigenproblem (Theorem 23.9.2); Section 10 proved that the best-fitting affine subspace is spanned by the leading singular vectors of the centered data matrix (Theorem 23.10.2) and turned "variance explained" into a theorem (Theorem 23.10.4); Section 11 built the graph Laplacian (Definition 23.11.1), identified its kernel (Theorem 23.11.2), introduced the Fiedler value (Definition 23.11.2) with the minimum it solves (Proposition 23.11.4) and the partition the signs of a Fiedler vector give, and proved the matrix-tree theorem (Theorem 23.11.8).
- **Speed.** Section 12 factored the Fourier matrix (Theorem 23.12.1) and solved the resulting recurrence (Theorem 23.12.2); this section factored the two-by-two product (Theorem 23.13.2), solved the resulting recurrence (Theorem 23.13.3), proved the one lower bound on ω this book has (Proposition 23.13.1), and showed what the speed costs (Theorem 23.13.6).

Four moves carried the chapter.

- **Conditioning belongs to the problem, stability to the algorithm, and the two multiply.** Chapter 15 §08 stated the distinction and could not use it; Theorem 23.1.3 makes it a theorem, and every accuracy claim in the chapter is an instance. *Transfer:* when an answer is wrong, ask first whether any method could have done better. If the condition number says no, do not change the algorithm — change the problem.
- **Measure an answer by a change in the data that makes it exact.** A forward error is usually unknowable and a backward error is usually computable, so prove the backward statement and let Theorem 23.1.3 supply the rest (§§01, 02, 03). *Transfer:* when a quantity you want to bound is out of reach, look for a perturbation of the input that the computed output answers exactly; bounding that is often elementary.

- **Every eigenvalue algorithm iterates, because no finite one can exist.** Chapter 10 §08 gave the reason — a finite procedure using arithmetic and radicals would solve the general quintic — and Sections 4 to 7 are what is left once that door is shut: a sequence of subspaces, each cheap to extend, each carrying a certified error bar from Chapter 19. *Transfer:* when exact solution is impossible in principle, the design question becomes what to iterate *in*; the Krylov space is the answer whenever the only affordable operation is one matrix–vector product.
- **A fast algorithm is a factorization.** The Fourier matrix factors into sparse pieces and the two-by-two product factors into seven multiplications; in both cases the cost follows by solving a recurrence exactly, and in both cases the underlying object is unchanged (§§12, 13). *Transfer:* to make an operation fast, do not look for a shortcut in the arithmetic. Look for a factorization of the operation itself, and count the recursive calls against the size reduction.

The chapter paid the following promises, in the words in which they were made.

The promise	Made in	Paid by
"whether a given method keeps that promise is stability, and it is Chapter 23's subject"	Chapter 15 §08	§01
"Chapter 23 draws the distinction properly, defines backward stability, and proves which of the algorithms in this book have it"	Chapter 15 §08	§01, §02, §03
"An error analysis of this kind, which measures an answer by a change in the data that makes it exact, is a **backward error analysis**. Chapter 23 builds on it."	Chapter 19 §04	§01
"Chapter 23 makes this precise" (the ε-pivot failure)	Chapter 2 §06	§02
"Chapter 23 reads Gaussian elimination itself as a sequence of Schur complements of 1×1 pivots"	Chapter 7 §03	§02
"Cholesky does about half the arithmetic of a general LU factorization ... it needs no pivoting"	Chapter 12 §02	§02
"Three things are *not* proved here, and all three belong to Chapter 23" (the second of them being that nothing in that chapter is about arithmetic)	Chapter 15 §08	§01, §02, §03

The promise	Made in	Paid by
"The conditioning of the least-squares problem itself is not $\kappa_2(\mathbf{A})$ ... a term in $\kappa_2(\mathbf{A})^2$ appears even for the QR route"	Chapter 15 §08	§03
"Chapter 23 makes 'sensitivity' precise and proves the comparison"	Chapter 10 §08, quoted again in Chapter 15 §08	§03
"a stable implementation of the QR route loses about $\log_{10}\kappa_2(\mathbf{A})$ decimal digits while forming and solving the normal equations loses about $2\log_{10}\kappa_2(\mathbf{A})$ — is still Chapter 23's to prove"	Chapter 15 §08	§03
"Chapter 23 quantifies the loss" (the Householder sign choice)	Chapter 10 §08	§03
"Chapter 23 explains why it is the stable one" (reflections against classical Gram–Schmidt)	Chapter 10 §02	§03
"Chapter 23 builds an iteration on it" (the Rayleigh quotient)	Chapter 16 §01 and Chapter 19 §06	§04
"the iteration $\mathbf{x} \mapsto \mathbf{A}\mathbf{x}$ is the power method, and Chapter 23 studies how fast it converges"	Chapter 18 §04	§04
"Chapter 23 studies it for general matrices, where the rate is governed by the ratio of the two largest eigenvalue moduli"	Chapter 18 §08	§04
"the power method, the algorithm that computes a Perron vector at the size of the web, belongs to Chapter 23"	Chapter 18 §09	§04
"Chapter 23 develops that iteration and explains why every implementation starts with the reduction proved here"	Chapter 10 §08	§05
"algorithms that compute eigenvalues, is the subject of Chapter 23"	Chapter 19 §11	§04, §05, §06

The promise	Made in	Paid by
"Those steps need a probabilistic model, a reason to prefer squared error, and an argument that the sample answer says something about the population. Chapter 23 supplies them"	Chapter 12 §10	§10, for the first two; the third is refused, below
"the graph Laplacian, returns in Chapter 23"	Chapter 2 §07	§11
the matrix-tree theorem, "which Chapter 23 completes"	Chapter 6 §07	§11
"Chapter 23 develops it, together with the cost accounting that makes 'quickly' precise" (the fast Fourier transform)	Chapter 11 §09	§12

Some things the chapter did not do, and the chapter's index collects them in one list. Section 2 proved the backward error of a factorization for the ordering it displays and stated with credit that Chapter 2's ordering satisfies the same bound; it also showed that the growth bound for partial pivoting is far too large to prove stability, and said so rather than tidying it. Section 3 proved the backward error of a single reflection and stated with credit both the accumulation over a whole factorization and the rates at which classical and modified Gram–Schmidt lose orthogonality. Section 4 stated, and did not prove, that Rayleigh quotient iteration converges at a quadratic rate, not a cubic one, for a general diagonalizable matrix. Section 5 quoted the theorem of Abel and Ruffini, which is why every eigenvalue method here iterates, and proved the first column of the convergence theorem of the QR algorithm while stating the general form with credit. Section 6 stated the classical convergence estimate for the extreme Ritz values and proved the clean special case alone, and described the loss of orthogonality in Lanczos without analyzing it. Section 8 derived the continuous Toda statement only after granting that $t \mapsto \mathbf{Q}(t)$ is differentiable, which is analysis this book has not set up; its discrete half, Theorem 23.8.5, rests on nothing unproved. Section 10 proved every deterministic statement about principal components and said plainly that the inference from a sample to a larger population is statistics, which this book does not develop; Chapter 12 §10 promised that inference, and promised as well an account of how a singular value decomposition is actually computed for a large matrix, which no section here gives — §10 says which route to avoid and why, and points at the orthogonal reductions of §§03 and 05, and there it stops. Both over-promises are recorded rather than hidden. In this section, the recursive form of Strassen's error bound, Winograd's lower bound of seven multiplications, the equality of the two definitions of ω, everything known about ω below $\log_2 7$, and Laderman's twenty-three-product identity were stated with credit and not proved.

Nothing in this book is proved from any of them. Each is quoted exactly where a reader would otherwise expect a proof, and every theorem in the chapter either proves its own case or carries what it needs as an explicit hypothesis; since all of them enter the book here, no earlier chapter can rest on them either. The one place a quoted result is used at all is Exercise (C1: Would twenty-three products for three-by-three beat Strassen?) (b), where Laderman's identity is handed to the reader as a hypothesis and the deduction from it is the reader's own. Chapter 20's quoted fact **(A7)** was not used anywhere in this chapter, and no analysis beyond Chapter

15's **(A1)**–**(A6)** was imported.

The book's account of computation ends here. Twenty chapters built objects and proved things about them; this one asked what it costs to produce those objects from data of finite accuracy, and found that the answer splits cleanly in two. How much accuracy the data deserve is a question about the problem, answered by a condition number. How much of that the algorithm delivers is a question about the algorithm, answered by a backward error. Everything in this chapter — the pivoting, the reflections, the shifts, the Krylov spaces, the seven products — is an attempt to keep the second small when the first is out of our hands.

23.13.8 Exercises

23.13.8.1 A. Check your understanding

Exercise A1.

(a) State how many arithmetic operations Definition 0.9.9 uses for the product of two $n \times n$ matrices, separating multiplications from additions.

(b) Define the exponent ω, and state what is proved about it in this section.

(c) True or false: Theorem 23.13.2 shows that $M(2) \leq 7$. Justify your answer.

(d) Which properties of $m \times m$ matrices does the proof of Theorem 23.13.2 use? Say what would go wrong if the identity had needed two blocks to commute.

(e) State the difference between the error bound of Proposition 23.13.4 and that of Proposition 23.13.5, and say for which matrices the difference matters.

Solution.

(a) n^3 multiplications and $n^2(n-1)$ additions, $2n^3 - n^2$ operations in all: each of the n^2 entries is a sum of n products, needing n multiplications and $n-1$ additions.

(b) $\omega = \inf\{\tau : M(n) = O(n^\tau)\}$, with $M(n)$ the arithmetic cost of Definition 23.13.1. Proved here: $\omega \geq 2$ (Proposition 23.13.1) and $\omega \leq \log_2 7$ (Theorem 23.13.3). Everything else quoted about ω is stated with credit and not proved.

(c) False, and for two reasons. The cost of Definition 23.13.1 counts additions as well as multiplications, and Theorem 23.13.2 uses 18 of them, so its cost at $n = 2$ is 25, not 7; indeed $M(2) \leq 12$ by the classical program, which is better. The number 7 counts multiplications only.

(d) Only the associativity and distributivity of matrix addition and multiplication and the existence of additive inverses, together with Theorem 7.1.1, which says that the blocks of $\mathbf{AB}$ are the eight products combined as for a 2×2 matrix. No block is ever inverted and no two are ever interchanged. If some cancellation had required, say, $\mathbf{A}_{11}\mathbf{B}_{22} = \mathbf{B}_{22}\mathbf{A}_{11}$, it would fail for general blocks, which do not commute, and the identity would be true for numbers and false for matrices — so the recursion of Theorem 23.13.3 would be unavailable, which is the only reason the identity is of any interest.

(e) Proposition 23.13.4 bounds the (i, j) error by $\gamma_n(|\mathbf{A}||\mathbf{B}|)_{ij}$, a quantity attached to that entry; Proposition 23.13.5 bounds every error by a multiple of $\max|a_{ij}| \max|b_{ij}|$, a quantity attached to the whole matrices. They agree in strength when all entries of $\mathbf{AB}$ are of comparable size, and differ when some entry of the product is far

smaller than others, as in Example (A small entry lost entirely).

23.13.8.2 B. Practice

Exercise B1: Seven products by hand.

Let $\mathbf{A} = \begin{pmatrix} 2 & -1 \\ 0 & 3 \end{pmatrix}$ and $\mathbf{B} = \begin{pmatrix} 1 & 4 \\ -2 & 1 \end{pmatrix}$. Compute $\mathbf{P}_1, \dots, \mathbf{P}_7$ of Theorem 23.13.2 with blocks of size 1, assemble the four entries, and check the answer against Example (A product of square matrices). Hence state how many multiplications and how many additions you performed.

Solution. With $a_{11} = 2$, $a_{12} = -1$, $a_{21} = 0$, $a_{22} = 3$ and $b_{11} = 1$, $b_{12} = 4$, $b_{21} = -2$, $b_{22} = 1$,

$$\mathbf{P}_1 = (2+3)(1+1) = 10, \qquad \mathbf{P}_2 = (0+3)\cdot 1 = 3,$$
$$\mathbf{P}_3 = 2\cdot(4-1) = 6, \qquad \mathbf{P}_4 = 3\cdot(-2-1) = -9,$$
$$\mathbf{P}_5 = (2-1)\cdot 1 = 1, \qquad \mathbf{P}_6 = (0-2)(1+4) = -10,$$
$$\mathbf{P}_7 = (-1-3)(-2+1) = 4.$$

Then

$$c_{11} = 10 - 9 - 1 + 4 = 4, \qquad c_{12} = 6 + 1 = 7,$$
$$c_{21} = 3 - 9 = -6, \qquad c_{22} = 10 + 6 - 3 - 10 = 3.$$

So $\mathbf{AB} = \begin{pmatrix} 4 & 7 \\ -6 & 3 \end{pmatrix}$, which is the product computed in Example (A product of square matrices).

The count: seven multiplications, and ten additions to form the operands together with eight to assemble the answer, so eighteen additions, twenty-five operations in all. The classical route uses eight multiplications and four additions, twelve operations. At this size the exchange is a loss.

Exercise B2: One block, one level.

Let

$$\mathbf{A} = \begin{pmatrix} 1 & 0 & 2 & 1 \\ 0 & 1 & 1 & 0 \\ 1 & 1 & 0 & 2 \\ 0 & 2 & 1 & 1 \end{pmatrix}, \qquad \mathbf{B} = \begin{pmatrix} 1 & 2 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 2 & 0 & 1 & 1 \\ 1 & 1 & 0 & 1 \end{pmatrix},$$

partitioned into 2×2 blocks. Compute $\mathbf{P}_3$ and $\mathbf{P}_5$ of Theorem 23.13.2, hence the $(1,2)$ block of $\mathbf{AB}$, and verify it against the block formula $\mathbf{A}_{11}\mathbf{B}_{12} + \mathbf{A}_{12}\mathbf{B}_{22}$.

Solution. The blocks are

$$\mathbf{A}_{11} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \mathbf{A}_{12} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}, \quad \mathbf{B}_{12} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \mathbf{B}_{22} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}.$$

Then $\mathbf{B}_{12} - \mathbf{B}_{22} = \begin{pmatrix} -1 & 0 \\ 1 & -1 \end{pmatrix}$ and $\mathbf{A}_{11} + \mathbf{A}_{12} = \begin{pmatrix} 3 & 1 \\ 1 & 1 \end{pmatrix}$, so

$$\mathbf{P}_3 = \mathbf{A}_{11}(\mathbf{B}_{12} - \mathbf{B}_{22}) = \begin{pmatrix} -1 & 0 \\ 1 & -1 \end{pmatrix}, \qquad \mathbf{P}_5 = \begin{pmatrix} 3 & 1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 3 & 4 \\ 1 & 2 \end{pmatrix}.$$

Hence

$$\mathbf{P}_3 + \mathbf{P}_5 = \begin{pmatrix} 2 & 4 \\ 2 & 1 \end{pmatrix}.$$

Directly, $\mathbf{A}_{11}\mathbf{B}_{12} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $\mathbf{A}_{12}\mathbf{B}_{22} = \begin{pmatrix} 2 & 3 \\ 1 & 1 \end{pmatrix}$, whose sum is $\begin{pmatrix} 2 & 4 \\ 2 & 1 \end{pmatrix}$. The two agree, and by Theorem 7.1.1 this is rows $1, 2$ and columns $3, 4$ of $\mathbf{AB}$.

Exercise B3: Counting the recursion.

Let $n = 2^p$.

(a) How many multiplications does the recursion of Theorem 23.13.3 perform, as a function of p? How many does the classical recipe perform?

(b) Using $T(n) = 7n^{\log_2 7} - 6n^2$, compute $T(n)$ and $2n^3 - n^2$ for $n = 8$ and $n = 64$.

(c) Hence say, for these two sizes, which recipe uses fewer operations.

Solution.

(a) Each level replaces one product of size $2m$ by seven of size m, and a product of size 1 is one multiplication, so the recursion performs $7^p = n^{\log_2 7}$ multiplications. The classical recipe performs $n^3 = 8^p$.

(b) For $n = 8$, that is $p = 3$: $T(8) = 7 \cdot 343 - 6 \cdot 64 = 2401 - 384 = 2017$, while $2 \cdot 512 - 64 = 960$. For $n = 64$, that is $p = 6$: $T(64) = 7 \cdot 117\,649 - 6 \cdot 4096 = 823\,543 - 24\,576 = 798\,967$, while $2 \cdot 262\,144 - 4096 = 520\,192$.

(c) At both sizes the classical recipe wins, by a factor of about 2.1 at $n = 8$ and about 1.5 at $n = 64$. The ratio is shrinking, and it crosses 1 between $n = 512$ and $n = 1024$; recursing all the way to scalars is a losing strategy at any size a person would compute by hand.

23.13.8.3 C. Going deeper

Exercise C1: Would twenty-three products for three-by-three beat Strassen?.

Suppose a ring identity multiplies two 3×3 matrices with $q > 9$ multiplications of combinations of entries, together with some fixed number of additions, and is used recursively on 3×3 block matrices.

(a) Show that the recursion performs q^p multiplications on matrices of size $n = 3^p$, and deduce that it gives $\omega \le \log_3 q$.

(b) You are given that such an identity exists with $q = 23$; this is a result of Laderman, which is not proved here. Determine whether recursing on it beats Theorem 23.13.3. Justify your answer.

(c) Determine the largest q for which such an identity *would* beat Theorem 23.13.3.

Hint: compare logarithms to a common base.

Solution.

(a) One level replaces a product of size $3m$ by q products of size m, so by induction on p the recursion performs q^p multiplications at size $n = 3^p$, the case $p = 0$ being one multiplication. The additions at one level cost Cm^2 for a constant C depending only on the identity, so the operation count satisfies $T(3m) = qT(m) + Cm^2$ with $T(1) = 1$. Unrolling,

$$T(3^p) = q^p + C\sum_{j=0}^{p-1} q^j\, 9^{p-1-j} = q^p + C\,9^{p-1}\,\frac{(q/9)^p - 1}{(q/9) - 1} \;\le\; q^p\Big(1 + \frac{C}{q-9}\Big),$$

where the last step uses $q > 9$ and drops the -1. So $T(n) \le cn^{\log_3 q}$ with $c = 1 + C/(q-9)$, since $q^p = n^{\log_3 q}$. Padding to a power of three as in Theorem 23.13.3 extends this to all n, so $\omega \le \log_3 q$.

(b) No. $\log_3 23 = \ln 23/\ln 3 = 3.13549\ldots/1.09861\ldots = 2.85404\ldots$, while $\log_2 7 = 2.80735\ldots$. Since $2.854 > 2.807$, the exponent obtained from 23 products at size 3 is worse than Strassen's.

(c) We need $\log_3 q < \log_2 7$, that is $q < 3^{\log_2 7}$. Now $3^{\log_2 7} = e^{(\log_2 7)\ln 3} = e^{3.08398\ldots} = 21.8498\ldots$, so the condition is $q \le 21$. Indeed $\log_3 21 = 3.04452\ldots/1.09861\ldots = 2.77124\ldots < \log_2 7$, while $\log_3 22 = 3.09104\ldots/1.09861\ldots = 2.81359\ldots > \log_2 7$. So an identity with 21 multiplications would beat Strassen and one with 22 would not.

Exercise C2: Where the entrywise bound really fails.

Let $\varepsilon > 0$ and $\mathbf{A} = \mathbf{B} = \begin{pmatrix} 1 & \varepsilon \\ \varepsilon & \varepsilon \end{pmatrix}$.

(a) Compute $\mathbf{AB}$ and $|\mathbf{A}||\mathbf{B}|$ exactly, and identify the entry of $\mathbf{AB}$ that is smallest as $\varepsilon \to 0$.

(b) Compute $\mathbf{P}_1, \ldots, \mathbf{P}_7$ exactly, and find which of them is largest as $\varepsilon \to 0$.

(c) Suppose $\varepsilon, 2\varepsilon, 1-\varepsilon, 1+\varepsilon, 1+2\varepsilon$ and $2\varepsilon^2$ are representable, and that the model rounds $(1+\varepsilon)^2$ to $1+2\varepsilon$ and $(\varepsilon-1)(1+\varepsilon)$ to -1, each time losing a trailing ε^2. Determine $\widehat{c}_{22}$, and the least constant c for which $|\widehat{\mathbf{C}} - \mathbf{AB}| \le cu|\mathbf{A}||\mathbf{B}|$ can hold at the $(2,2)$ position.

Hint: with $\varepsilon = 2^{-27}$ in 53-bit binary arithmetic, both roundings are what rounding to nearest does.

Solution.

(a) $\mathbf{AB} = \begin{pmatrix} 1+\varepsilon^2 & \varepsilon+\varepsilon^2 \\ \varepsilon+\varepsilon^2 & 2\varepsilon^2 \end{pmatrix}$, and since every entry of $\mathbf{A}$ and $\mathbf{B}$ is positive, $|\mathbf{A}||\mathbf{B}| = \mathbf{AB}$. The smallest entry as $\varepsilon \to 0$ is the $(2,2)$ entry $2\varepsilon^2$.

(b) With $a_{11} = b_{11} = 1$ and all other entries ε,

$$\mathbf{P}_1 = (1+\varepsilon)^2, \quad \mathbf{P}_2 = 2\varepsilon, \quad \mathbf{P}_3 = 0, \quad \mathbf{P}_4 = \varepsilon^2 - \varepsilon,$$
$$\mathbf{P}_5 = \varepsilon + \varepsilon^2, \quad \mathbf{P}_6 = \varepsilon^2 - 1, \quad \mathbf{P}_7 = 0.$$

As $\varepsilon \to 0$ the largest in modulus is $\mathbf{P}_1 \to 1$, with $\mathbf{P}_6 \to -1$ beside it; the other five all tend to 0.

(c) The $(2,2)$ entry is assembled as $\mathbf{P}_1 + \mathbf{P}_3 - \mathbf{P}_2 + \mathbf{P}_6$, and by (b) this is $(1 + 2\varepsilon + \varepsilon^2) + 0 - 2\varepsilon + (\varepsilon^2 - 1) = 2\varepsilon^2$, as it must be. Two of the four terms have modulus close to 1, and the two occurrences of ε^2 that survive the cancellation are exactly the two the model throws away: every operand that enters the $(2,2)$ entry — $a_{11} + a_{22} = b_{11} + b_{22} = b_{11} + b_{12} = 1 + \varepsilon$, $a_{21} + a_{22} = 2\varepsilon$, $b_{12} - b_{22} = 0$ and $a_{21} - a_{11} = \varepsilon - 1$ — are all representable, so each is formed exactly, and then by hypothesis $\widehat{\mathbf{P}}_1 = 1 + 2\varepsilon$ and $\widehat{\mathbf{P}}_6 = -1$, while $\widehat{\mathbf{P}}_3 = 0$ and $\widehat{\mathbf{P}}_2 = 2\varepsilon$ are exact. Assembling left to right,

$$\mathrm{fl}\big((1+2\varepsilon) + 0\big) = 1 + 2\varepsilon, \quad \mathrm{fl}\big((1+2\varepsilon) - 2\varepsilon\big) = 1, \quad \mathrm{fl}\big(1 + (-1)\big) = 0,$$

so $\widehat{c}_{22} = 0$ and the error is $2\varepsilon^2$. Since $(|\mathbf{A}||\mathbf{B}|)_{22} = 2\varepsilon^2$ by (a), an entrywise bound there reads $2\varepsilon^2 \le cu \cdot 2\varepsilon^2$, so the least admissible constant is $c = 1/u$, exactly as in Theorem 23.13.6. The mechanism is the same: a quantity of size ε^2 is carried inside numbers of size 1, where the model cannot see it.

Exercise C3: Only the products recurse.

Suppose someone proposes an identity that multiplies 2×2 matrices with eight multiplications but only two additions, and recurses on it.

(a) Write down the recurrence for its operation count with $T(1) = 1$, and solve it exactly for $n = 2^p$.

(b) Hence determine the exponent it gives, and compare with Theorem 23.13.3.

(c) Explain in one sentence what part of an identity the exponent depends on.

Solution.

(a) Two block additions of size $m \times m$ cost $2m^2$, so $T(2m) = 8T(m) + 2m^2$ with $T(1) = 1$. We claim $T(2^p) = \frac{3}{2} \cdot 8^p - \frac{1}{2} \cdot 4^p$. For $p = 0$ this is $\frac{3}{2} - \frac{1}{2} = 1$. Assuming it for p and taking $m = 2^p$, so $m^2 = 4^p$,

$$T(2^{p+1}) = 8\Big(\tfrac{3}{2}8^p - \tfrac{1}{2}4^p\Big) + 2 \cdot 4^p = \tfrac{3}{2}8^{p+1} - 4 \cdot 4^p + 2 \cdot 4^p = \tfrac{3}{2}8^{p+1} - \tfrac{1}{2}4^{p+1},$$

since $-4 + 2 = -2$ and $-2 \cdot 4^p = -\frac{1}{2}4^{p+1}$. (Check: $T(2) = 10$, $T(4) = 88$, $T(8) = 736$.)

(b) With $n = 2^p$ this is $T(n) = \frac{3}{2}n^3 - \frac{1}{2}n^2$, so the exponent is 3. Saving additions changed the constant from 2 to $\frac{3}{2}$ and nothing else; Theorem 23.13.3 changed the exponent from 3 to $\log_2 7$.

(c) Only the number of *multiplications* recurses, so only that number enters the exponent; the additions contribute to the constant.

Notation

This page is a reference, not a section: there is nothing to work through here, and it carries no exercises and no quick checks. Use it when you meet a symbol and want to know what it means and where the book fixed it. The symbols are grouped by the kind of thing they name, not by chapter, because a reader arrives with a symbol and not with a chapter number. Every entry links to the place where the book defines it; follow the link for the hypotheses, which a one-line gloss cannot carry.

Read the conventions first. Most of what looks like a clash between two symbols is resolved by one of them.

23.0.1 The standing conventions

The field. F is an arbitrary field throughout, and $\mathbb{F}_p$ is the field with p elements (Definition 0.7.1). Chapters 10 to 12 and much of Part V need $\mathbb{R}$ or $\mathbb{C}$, and say so where they do. Vector spaces are V, U, W, plain italic, and are finite-dimensional unless the statement says otherwise.

Bold is for matrices and vectors, never for maps or spaces. A matrix is a bold upright capital, $\mathbf{A}$; a vector is a bold lowercase letter, $\mathbf{v}$; an operator or linear map is plain italic, T; a space is plain italic, V. Entries stay plain: a_{ij}, or $(\mathbf{A})_{ij}$. A Greek letter naming a matrix is bold too, as $\mathbf{\Lambda}$ or $\mathbf{\Sigma}$.

Maps and composition. Linear maps are $T, S \colon V \to W$, never f. Composition is written ST, and it means: first T, then S. For functions in general the book writes $g \circ f$.

Coordinates. $[\mathbf{v}]_{\mathcal{B}}$ is the coordinate vector of $\mathbf{v}$ in the ordered basis $\mathcal{B}$ (Definition 1.5.2), and $[T]_{\mathcal{B}}^{\mathcal{C}}$ is the matrix of T with input basis $\mathcal{B}$ and output basis $\mathcal{C}$ (Definition 3.6.1). The input basis is the subscript, the output basis the superscript; when the two agree the book writes $[T]_{\mathcal{B}}$. A basis is an **ordered** list, written in parentheses.

Transpose and adjoint. $\mathbf{A}^{\top}$ is the transpose (Definition 0.9.10) and $\mathbf{A}^{*}$ the conjugate transpose (Definition 10.1.2), which is also the symbol for the adjoint of an operator (Definition 10.6.1). The prime T' is the dual map (Definition 4.4.1), and never a derivative of a map.

Inner products are linear in the first slot and conjugate-linear in the second (Definition 10.1.1). Over $\mathbb{R}$ the distinction disappears.

Ordering of eigenvalues and singular values. For Hermitian $\mathbf{A}$, the eigenvalues are listed **decreasing**, $\lambda_1(\mathbf{A}) \geq \cdots \geq \lambda_n(\mathbf{A})$, with multiplicity. Singular values are listed decreasing as well, $\sigma_1(\mathbf{A}) \geq \sigma_2(\mathbf{A}) \geq \cdots \geq 0$ (Definition 12.8.1). Where a proof wants the increasing order it says so.

Indices start at 1, with three announced exceptions: Chapter 11 §09, where circulant and Fourier subscripts run from 0 to $n-1$ and are read modulo n; Chapter 21 §§06 to 10, where the coordinates of F^{n+1} run from 0 so that $\mathbb{P}^n(F)$ has dimension n (Definition 21.6.2); and Chapter 22 §09, which follows Chapter 11 §09 for group elements and characters.

Defining, not asserting. $\coloneqq$ means "is defined to be". A plain $=$ asserts an equality that has been or will be proved.

23.0.2 Numbers, sets and fields

Symbol	Meaning	Defined at
$\mathbb{N}, \mathbb{Z}, \mathbb{Q}, \mathbb{R}, \mathbb{C}$	natural numbers (with 0), integers, rationals, reals, complex numbers	Definition 0.3.1
F, $\mathbb{F}_p$	a field; the field with p elements	Definition 0.7.1
$\operatorname{char} F$	characteristic of a field: the least $n > 0$ with $n \cdot 1 = 0$, or 0	Definition 0.7.2
$\overline{z}$, $\lvert z \rvert$	complex conjugate and modulus	Definition 0.6.2
$\{x \in S : P(x)\}$	set-builder notation, with a colon	Definition 0.3.2
$\emptyset$, $S \subseteq T$	the empty set; inclusion	Definition 0.3.3, Definition 0.3.4
$S \cup T$, $S \cap T$, $S \setminus T$, S^c	union, intersection, difference, complement	Definition 0.3.6, Definition 0.3.7, Definition 0.3.8
$S \times T$, $(x_1, \ldots, x_n)$	Cartesian product and n-tuples	Definition 0.3.10, Definition 0.3.11
$\mathcal{P}(S)$	power set, the set of all subsets	Definition 0.3.12
$f\colon X \to Y$, $x \mapsto f(x)$	a function and its rule	Definition 0.4.1
$f(A)$, $f^{-1}(B)$	image of a subset, preimage of a subset	Definition 0.4.2
$g \circ f$, id_X, f^{-1}	composition, identity function, inverse function	Definition 0.4.4, Definition 0.4.5, Definition 0.4.7
$x \sim y$, $[x]$, $X/\!\sim$	equivalence relation, equivalence class, quotient set	Definition 0.5.2, Definition 0.5.3, Definition 0.5.5
S_n, $\operatorname{sgn}(\sigma)$, $\operatorname{inv}(\sigma)$	symmetric group; sign of a permutation; number of inversions	Example (Groups), Definition 6.3.2, Definition 6.3.1
A_n	alternating group, the even permutations	Definition 6.3.3
$F[x]$, $F[x]_{\leq n}$	polynomials over F; those of degree at most n	Definition 0.8.2, Definition 0.8.4
$\deg p$, $p(c)$	degree; evaluation at a scalar	Definition 0.8.3, Definition 0.8.6
$p \mid q$, $\gcd(p, q)$, $\operatorname{lcm}(p, q)$	divisibility, greatest common divisor, least common multiple in $F[x]$	Definition 5.1.1, Definition 5.2.2, Definition 5.2.4
$\langle p \rangle$	the ideal of $F[x]$ generated by p: all multiples of p	Definition 5.2.1
$\operatorname{mult}_c(f)$	multiplicity of c as a root of f	Definition 5.4.1
p'	formal derivative of a polynomial	Definition 5.4.3
ℓ_i	Lagrange basis polynomial, $\ell_i(c_j) = \delta_{ij}$	Definition 5.6.1

23.0.3 Spaces

Symbol	Meaning	Defined at
V, U, W	vector spaces over F; U is usually a subspace	Definition 1.1.1, Definition 1.2.1
F^n, F^S	column vectors; **all** functions $S \to F$	Definition 1.1.1
$F^{(S)}$	the free vector space on S: the **finitely supported** functions $S \to F$	Definition 14.2.3
$M_{m\times n}(F)$, $M_n(F)$	matrices over F	Definition 0.9.1
$\operatorname{span}(S)$	span; the span of the empty set is $\{\mathbf{0}\}$	Definition 1.3.2
$\dim V$, $\dim_F V$	dimension, over F when the field matters	Definition 1.6.1
$\mathcal{B} = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$	an **ordered** basis; $\mathcal{E}$ is the standard basis	Definition 1.5.1, Example (Standard Bases)
$[\mathbf{v}]_{\mathcal{B}}$	coordinate vector of $\mathbf{v}$ in $\mathcal{B}$	Definition 1.5.2
$U + W$, $U \oplus W$	sum of subspaces; internal direct sum	Definition 1.7.1, Definition 1.7.2
$V \times W$	product of vector spaces (the external direct sum)	Definition 3.9.1
$\mathbf{v} + U$, V/U	coset; quotient space	Definition 3.9.2, Definition 3.9.3
$\operatorname{codim} U$	codimension, $\dim V/U$	Definition 4.5.1
V^*, φ	dual space; a linear functional, always a Greek letter	Definition 4.1.2, Definition 4.1.1
$\varphi_1, \ldots, \varphi_n$	the dual basis of $\mathcal{B}$	Definition 4.1.3
U^0	annihilator of U inside V^*	Definition 4.2.1
V^{**}, $\mathrm{ev}_{\mathbf{v}}$	double dual; evaluation at $\mathbf{v}$	Definition 4.3.1
$V_{\mathbb{C}}$	complexification of a real space	Definition 1.9.2
$\mathcal{F}$	a family of operators in $\mathcal{L}(V)$	Definition 8.9.1

23.0.4 Vectors, matrices and their operations

Symbol	Meaning	Defined at
$\mathbf{v}, \mathbf{u}, \mathbf{w}, \mathbf{x}, \mathbf{y}$	vectors: bold lowercase	Definition 1.1.2
$\mathbf{0}$, $\mathbf{1}$	the zero vector; the all-ones vector	Definition 1.1.2, Definition 8.11.1
$\mathbf{e}_1, \ldots, \mathbf{e}_n$	the standard basis of F^n	Example (Standard Bases)
$\mathbf{E}_{ij}$	matrix unit: 1 in entry (i, j), zeros elsewhere	Example (Standard Bases)
$\mathbf{A}, \mathbf{B}, \mathbf{C}$, a_{ij}	matrices, bold upright capitals; their entries, plain	Definition 0.9.1
$0_{m\times n}$, $\mathbf{I}$, $\mathbf{I}_n$	zero matrix, plain (bold $\mathbf{0}$ as a block); identity matrix	Definition 0.9.2, Definition 0.9.3
δ_{ij}	Kronecker delta: 1 when $i = j$, else 0	Definition 0.9.3
$\operatorname{diag}(d_1, \ldots, d_n)$	the diagonal matrix with these diagonal entries	Definition 0.9.4
$\mathbf{A}^\top$, $\mathbf{A}^*$	transpose; conjugate transpose	Definition 0.9.10, Definition 10.1.2
$\operatorname{tr} \mathbf{A}$	trace, the sum of the diagonal entries	Definition 0.9.12
$\det \mathbf{A}$	determinant	Definition 6.4.1

Symbol	Meaning	Defined at
$\operatorname{adj}\mathbf{A}$	adjugate, the transposed matrix of cofactors	Definition 6.6.2
M_{ij}, C_{ij}	minor and cofactor $(-1)^{i+j}M_{ij}$	Definition 6.6.1
$\mathbf{A}^{-1}$	inverse of a non-singular matrix	Definition 0.9.13
$p(\mathbf{A})$	a polynomial evaluated at a matrix	Definition 0.9.14
$\mathbf{P}_{ij}$, $\mathbf{D}_i(c)$, $\mathbf{I}+c\mathbf{E}_{ij}$	the three elementary matrices: swap, scale, add	Definition 2.4.1
$\mathbf{P}_\sigma$	permutation matrix	Definition 2.6.2
$\mathbf{A}=\text{Ł}\mathbf{U}$, $\mathbf{PA}=\text{Ł}\mathbf{U}$	the LU and PLU factorizations	Definition 2.6.1, Definition 2.6.3
$\operatorname{col}(\mathbf{A})$, $\operatorname{row}(\mathbf{A})$, $\operatorname{nul}(\mathbf{A})$	column space, row space, null space	Definition 2.5.1, Definition 2.5.2, Definition 2.5.3
$\operatorname{rank}\mathbf{A}$, $\operatorname{nullity}\mathbf{A}$	rank and nullity of a matrix	Definition 2.5.4, Definition 2.5.5
$\mathbf{A}\sim\mathbf{B}$	similar: $\mathbf{B}=\mathbf{P}^{-1}\mathbf{AP}$	Definition 3.7.2
$\mathbf{A}\simeq\mathbf{B}$	congruent: $\mathbf{B}=\mathbf{P}^{\top}\mathbf{AP}$	Definition 13.2.1
$\mathbf{A}\approx\mathbf{B}$	equivalent over $F[x]$: $\mathbf{B}=\mathbf{UAV}$ with $\mathbf{U},\mathbf{V}$ invertible over $F[x]$	Definition 9.7.2
equivalent matrices	$\mathbf{B}=\mathbf{QAP}$ with $\mathbf{P},\mathbf{Q}$ non-singular	Definition 3.8.1
$\mathbf{A}\oplus\mathbf{B}$	block diagonal matrix with the given square diagonal blocks	Definition 7.1.2
$\mathbf{M}/\mathbf{A}$, $\mathbf{M}/\mathbf{D}$	Schur complement of an invertible block of a block matrix	Definition 7.3.1
$\mathbf{A}\otimes\mathbf{B}$	Kronecker product	Definition 7.4.1
$\operatorname{vec}\mathbf{X}$	vectorization: the columns of $\mathbf{X}$ stacked into one column	Definition 7.4.2
$\mathbf{A}\circ\mathbf{B}$	Hadamard (entrywise) product	Definition 12.7.1
$[\mathbf{A},\mathbf{B}]=\mathbf{AB}-\mathbf{BA}$	commutator	Definition 7.5.1
$\mathbf{J}$	the all-ones matrix, every entry 1	Example (Orthogonally diagonalizing a 3 by 3 matrix)
$\mathbf{A}'(t)$, $\mathbf{x}'(t)$	entrywise derivative of a matrix- or vector-valued function of a real variable	Definition 15.6.1
$e^{\mathbf{A}}$, $f(\mathbf{A})$	matrix exponential; a function of a matrix through its Jordan form	Definition 9.9.2, Definition 9.9.1
$\lim_m \mathbf{A}^m$	entrywise convergence of matrices	Definition 9.10.1
$\mathbf{Ax}=\mathbf{b}$, $\mathbf{Ax}=\mathbf{0}$	a linear system and its homogeneous version	Definition 2.1.1, Definition 2.1.2
echelon form	the staircase shapes elimination produces	Definition 2.2.3, Definition 2.2.4

23.0.5 Maps and their spaces

Symbol	Meaning	Defined at
$T, S\colon V \to W$	linear maps; ST means first T, then S	Definition 3.1.1
$T_{\mathbf{A}}$	the map $F^n \to F^m$, $\mathbf{x} \mapsto \mathbf{Ax}$	Example (Multiplication by a Matrix)
$\ker T$, $\operatorname{im} T$	kernel and image	Definition 3.2.1, Definition 3.2.2
$\operatorname{rank} T$, $\operatorname{nullity} T$	$\dim \operatorname{im} T$ and $\dim \ker T$	Definition 3.3.2, Definition 3.3.1
$\mathcal{L}(V, W)$, $\mathcal{L}(V)$	all linear maps $V \to W$; the operators on V	Definition 3.4.1
$\operatorname{End}(V)$	the same space $\mathcal{L}(V)$, named as an **algebra** under composition	Definition 22.1.1
$p(T)$, id_V	a polynomial in an operator; the identity operator	Definition 3.4.2, Definition 3.1.1
$[T]_{\mathcal{B}}^{\mathcal{C}}$	matrix of T from the input basis $\mathcal{B}$ to the output basis $\mathcal{C}$	Definition 3.6.1
$[\mathrm{id}]_{\mathcal{B}}^{\mathcal{C}}$	change-of-coordinates matrix from $\mathcal{B}$ to $\mathcal{C}$	Definition 3.7.1
$V \cong W$	isomorphic vector spaces	Definition 3.5.2, Definition 3.5.3
T'	dual map $W^* \to V^*$; the star is kept for adjoints	Definition 4.4.1
$\operatorname{tr} T$, $\det T$	trace and determinant of an operator	Definition 3.10.2, Definition 6.5.1
$T\|_U$, $\bar{T}$	restriction of T to an invariant subspace; the operator it induces on V/U	Definition 8.1.1, Definition 8.1.2
$\mathrm{GL}_n(F)$, $\mathrm{SL}_n(F)$	general and special linear groups	Example (Groups), Theorem 6.5.9
$\mathcal{M}(V_1, \ldots, V_k; W)$	multilinear maps $V_1 \times \cdots \times V_k \to W$; the semicolon separates inputs from output	Definition 14.1.2

23.0.6 Inner products and norms

Symbol	Meaning	Defined at
$\langle \mathbf{u}, \mathbf{v} \rangle$	inner product: **linear in the first slot**, conjugate-linear in the second	Definition 10.1.1
$\langle \mathbf{A}, \mathbf{B} \rangle = \operatorname{tr}(\mathbf{B}^*\mathbf{A})$	the Frobenius inner product on matrices	Definition 10.1.1
$\|\mathbf{v}\|$	norm; the induced norm $\sqrt{\langle \mathbf{v}, \mathbf{v} \rangle}$ unless said otherwise	Definition 10.1.3, Definition 15.1.1
$\mathbf{u} \perp \mathbf{v}$, θ	orthogonal vectors; the angle between two non-zero real vectors	Definition 10.1.4, Definition 10.1.5
$\mathbf{G}$	Gram matrix of a list, $(\mathbf{G})_{ij} = \langle \mathbf{v}_j, \mathbf{v}_i \rangle$	Definition 10.2.3
$U^{\perp}$	orthogonal complement	Definition 10.3.1
P_U, $d(\mathbf{v}, U)$	orthogonal projection onto U; distance to U	Definition 10.3.2, Definition 10.3.3
T^*	adjoint of an operator	Definition 10.6.1
self-adjoint, normal	$T^* = T$; $T^*T = TT^*$	Definition 10.6.2, Definition 10.6.3
$\mathrm{O}(n)$, $\mathrm{SO}(n)$, $\mathrm{U}(n)$	orthogonal, special orthogonal and unitary groups	Definition 10.7.3

Symbol	Meaning	Defined at
$\mathbf{H_w}$, $\mathbf{G}(i,j;c,s)$	Householder reflection; Givens rotation	Definition 10.8.1, Definition 10.8.2
P_n, T_n	Legendre and Chebyshev polynomials	Definition 10.10.1, Definition 23.7.4
$\|\mathbf{x}\|_p$	the p-norm; q is the conjugate exponent, $1/p + 1/q = 1$	Definition 15.1.1, Corollary 17.11.5
$\|f\|_\infty$	sup norm on $C[0,1]$	Definition 15.1.1
$B_{\|\cdot\|}$, B_1, B_2, B_∞	closed unit ball of a norm; the balls of the three p-norms	Definition 15.1.2
$\|\mathbf{A}\|_F$	Frobenius norm, $\sqrt{\operatorname{tr}(\mathbf{A}^*\mathbf{A})}$; the subscript is obligatory	Lemma 11.11.1
$\|\mathbf{A}\|$, $\|\mathbf{A}\|_1$, $\|\mathbf{A}\|_\infty$	operator norm induced by a vector norm; largest column sum; largest row sum	Definition 15.3.2
$\kappa(\mathbf{A}) = \|\mathbf{A}\|\|\mathbf{A}^{-1}\|$	condition number	Definition 15.8.1
$\|\mathbf{y}\|_*$	dual norm, $\max_{\|\mathbf{x}\|\le 1}\langle \mathbf{x},\mathbf{y}\rangle$	Definition 17.4.4
$\|\!\|\!\|\mathbf{A}\|\!\|\!\|$, $\|\!\|\!\|\mathbf{A}\|\!\|\!\|_{(k)}$	unitarily invariant norm; the Ky Fan k-norm $\sigma_1 + \cdots + \sigma_k$	Definition 20.4.1, Definition 20.4.2
Φ, Φ^*	symmetric gauge function and its dual, with $\|\!\|\!\|\mathbf{A}\|\!\|\!\| = \Phi(\sigma(\mathbf{A}))$	Definition 20.3.1, Definition 20.3.3
$\langle \mathbf{x},\mathbf{y}\rangle_\mathbf{A}$, $\|\mathbf{x}\|_\mathbf{A}$	the inner product $\mathbf{y}^*\mathbf{A}\mathbf{x}$ of a positive definite $\mathbf{A}$, and its energy norm	Theorem 12.4.2, Definition 23.7.1
$\Theta(U,W)$, $\theta_1 \le \cdots \le \theta_k$	principal angles between two subspaces, in $[0,\pi/2]$	Definition 19.8.1

23.0.7 Bilinear forms, tensors and exterior algebra

Symbol	Meaning	Defined at
$\beta\colon V \times V \to F$, $q(\mathbf{v}) = \beta(\mathbf{v},\mathbf{v})$	bilinear form; the quadratic form it carries	Definition 13.1.1, Definition 13.3.2
$[\beta]_\mathcal{B}$	Gram matrix of a form, $\beta(\mathbf{v}_i,\mathbf{v}_j)$, indices uncrossed	Definition 13.1.2
$\operatorname{rad}(\beta)$	radical of a form; β is non-degenerate exactly when it is $\{\mathbf{0}\}$	Definition 13.1.3, Definition 13.1.4
discriminant	the square class of $\det[\beta]_\mathcal{B}$ in $F^\times$, the same for every basis	Definition 13.2.2
(n_+, n_-, n_0)	inertia of a real symmetric form; the signature is the pair (n_+, n_-)	Definition 13.5.1
$\operatorname{In}(\mathbf{A})$	inertia triple of a Hermitian matrix, by sign of eigenvalue	Definition 16.10.1
$\mathbf{H}_f(\mathbf{a})$	Hessian matrix of a twice-differentiable function at a point	Definition 13.6.2
isotropic, totally isotropic	$q(\mathbf{v}) = 0$ with $\mathbf{v} \neq \mathbf{0}$; a subspace on which β vanishes	Definition 13.7.1, Definition 13.7.2
hyperbolic plane, $\operatorname{ind}(\beta)$	the plane of a hyperbolic pair; the Witt index	Definition 13.7.3, Definition 13.7.4

Symbol	Meaning	Defined at
$U \perp W$	orthogonal direct sum for a form: the summands pair to zero	Definition 13.7.3
$(V, \beta) \cong (V', \beta')$	**isometric** bilinear spaces (this use of $\cong$ is local to forms)	Definition 13.8.1
$\mathrm{Isom}(\beta)$	isometry group of a form, $\{\mathbf{P} : \mathbf{P}^\top \mathbf{A}\mathbf{P} = \mathbf{A}\}$	Definition 13.10.1
$\mathrm{O}(p,q)$, $\mathbf{I}_{p,q}$, $\mathrm{Sp}(2m, F)$, $\mathbf{\Omega}_{2m}$	the indefinite orthogonal and symplectic groups and their standard matrices	Definition 13.10.2
$V \otimes W$, $\mathbf{v} \otimes \mathbf{w}$	tensor product and a simple tensor	Definition 14.2.1, Definition 14.2.2
$S \otimes T$, $\mathcal{B} \otimes \mathcal{C}$	tensor product of maps; the product basis, first factor slow	Definition 14.3.1, Definition 14.3.2
Θ	the isomorphism $V^* \otimes W \to \mathcal{L}(V, W)$	Theorem 14.3.9
C, C^a_b	contraction $V^* \otimes V \to F$; contraction of one upper against one lower slot	Definition 14.4.1, Definition 14.4.3
$T^p_q(V)$, $T^{i_1 \dots i_p}_{j_1 \dots j_q}$	mixed tensors of type (p, q) and their components	Definition 14.4.2, Definition 14.5.1
$V^{\otimes k}$, $\mathrm{T}(V)$	k-th tensor power, with $V^{\otimes 0} = F$; the tensor algebra	Definition 14.6.1, Definition 14.6.2
$\mathrm{Sym}^k V$, $\mathrm{Sym}(V)$	k-th symmetric power; the symmetric algebra, written by juxtaposition	Definition 14.7.2, Definition 14.7.3
$(V^{\otimes k})^{S_k}$	the symmetric tensors, fixed by every permutation of the slots	Definition 14.7.5
$F[x_1, \dots, x_n]$	the polynomial algebra in n variables	Definition 14.7.4
$\Lambda^k V$, $\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_k$	k-th exterior power and a wedge	Definition 14.8.2
ΛV, $\mathbf{e}_S$	exterior algebra; its basis element for an increasing index set	Definition 14.10.1
$\Lambda^k T$	exterior power of a linear map; on the top power it is $\det T$	Definition 14.9.1
$\varepsilon_{\mathbf{v}}$	wedging by a fixed vector, $\omega \mapsto \mathbf{v} \wedge \omega$	Lemma 14.9.1
$\mathcal{I}$, $\mathcal{I}_q$	a two-sided ideal of an algebra; the one whose quotient is the Clifford algebra	Definition 14.10.3, Definition 13.12.2
$\mathbb{H}$	the quaternions	Definition 13.12.3

23.0.8 Spectra and canonical forms

Symbol	Meaning	Defined at
$p_T(x) = \det(x\mathbf{I} - T)$	characteristic polynomial, monic	Definition 6.10.1, Definition 6.10.2
$m_T(x)$	minimal polynomial: the monic generator of the annihilating ideal	Definition 8.5.1, Definition 5.7.1
$\mathrm{spec}(T)$	spectrum, the set of eigenvalues	Definition 8.2.3
$E_\lambda(T) = \ker(T - \lambda I)$	eigenspace	Definition 8.2.1, Definition 8.2.2
$a_T(\lambda)$, $g_T(\lambda)$	algebraic and geometric multiplicity of λ	Definition 8.3.1, Definition 8.3.2
$G_\lambda(T)$	generalized eigenspace, $\ker(T - \lambda I)^n$	Definition 9.1.1, Definition 9.1.2

Symbol	Meaning	Defined at
$\mathbf{J}_k(\lambda)$	$k \times k$ Jordan block: λ on the diagonal, 1 on the **super**diagonal	Definition 9.3.1, Definition 9.3.2
$\mathbf{\Lambda}(\lambda)$, $\mathbf{C}_k(\lambda)$	rotation-scaling block of a conjugate pair; the real Jordan block built from it	Definition 9.4.1
$\mathbf{C}(p)$	companion matrix of a monic p	Definition 9.5.3
$Z(\mathbf{v}; T)$, $m_{T,\mathbf{v}}$	cyclic subspace generated by $\mathbf{v}$; the T-annihilator of $\mathbf{v}$	Definition 9.5.1, Definition 9.5.2
$d_1 \mid d_2 \mid \cdots \mid d_r$	invariant factors, with $d_r = m_T$; their prime powers are the elementary divisors	Definition 9.6.1
$\rho(\mathbf{A})$	spectral radius, the largest modulus in the spectrum	Definition 15.4.1
$\mathbf{\Pi}$	the limit $\lim_m \mathbf{A}^m$ of a convergent matrix	Theorem 9.10.4
$\mathbf{A} \succeq 0$, $\mathbf{A} \succ 0$	positive semidefinite, positive definite; Hermitian is implied	Definition 12.1.1
$\mathbf{A} \succeq \mathbf{B}$	the Loewner order, $\mathbf{A} - \mathbf{B} \succeq 0$	Definition 12.5.1
$\mathbf{A}^{1/2}$	the unique positive semidefinite square root	Theorem 12.2.1
$\lvert\mathbf{A}\rvert = (\mathbf{A}^*\mathbf{A})^{1/2}$	absolute value of a matrix	Definition 12.2.1
$\sigma_1(\mathbf{A}) \geq \cdots \geq \sigma_{\min(m,n)}(\mathbf{A})$	singular values, decreasing	Definition 12.8.1
$\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^*$	a singular value decomposition: $\mathbf{U}$ and $\mathbf{V}$ unitary, $\mathbf{\Sigma}$ the same size as $\mathbf{A}$ with the singular values on its diagonal and zeros elsewhere	Theorem 12.8.1
$\mathbf{A}^+$	Moore–Penrose pseudoinverse	Definition 12.11.1
$\lambda_1(\mathbf{A}) \geq \cdots \geq \lambda_n(\mathbf{A})$, $\boldsymbol{\lambda}(\mathbf{A})$	eigenvalues of a Hermitian matrix, decreasing; the vector of them	Definition 16.1.1, Definition 16.8.1
$R_{\mathbf{A}}(\mathbf{x})$, $R_T(\mathbf{v})$	Rayleigh quotient $\langle\mathbf{A}\mathbf{x}, \mathbf{x}\rangle / \langle\mathbf{x}, \mathbf{x}\rangle$	Definition 16.1.1
$s_k(\mathbf{A})$	Ky Fan partial sum $\lambda_1(\mathbf{A}) + \cdots + \lambda_k(\mathbf{A})$	Corollary 16.6.5
$\mathbf{d}(\mathbf{A})$	the diagonal vector $(a_{11}, \ldots, a_{nn})$ of a Hermitian matrix	Definition 16.8.1
$\mathcal{W} = (W_1, \ldots, W_k)$	a flag of subspaces, and a list adapted to it	Definition 16.7.1
$\mathcal{H}(\mathbf{A})$	Hermitian dilation, whose eigenvalues are $\pm\sigma_i(\mathbf{A})$ and zeros	Proposition 16.9.3
$r_i(\mathbf{A})$, $D_i(\mathbf{A})$	Gershgorin radius and disc	Definition 19.1.1
$O_{ij}(\mathbf{A})$	Brauer oval of Cassini	Theorem 19.2.1
$W(\mathbf{A})$	numerical range, $\{\mathbf{x}^*\mathbf{A}\mathbf{x} : \lVert\mathbf{x}\rVert_2 = 1\}$	Definition 19.2.1
$\mathbf{E}$, $\widetilde{\mathbf{A}}$	a perturbation, in $\mathbf{A} + \mathbf{E}$; a perturbed matrix when it is not of that shape	Definition 15.8.1
$\operatorname{sep}_F(\mathbf{A}, \mathbf{B})$	separation of two matrices in the Frobenius norm	Definition 19.7.1
$\kappa_{\mathbf{A}}(\lambda)$	condition number of a simple eigenvalue	Definition 19.11.1
$\mathcal{S}_{\mathbf{A},\mathbf{B}}$	Sylvester operator $\mathbf{X} \mapsto \mathbf{A}\mathbf{X} - \mathbf{X}\mathbf{B}$	Definition 11.10.1
$\mathbf{B} - \lambda\mathbf{A}$	a matrix pencil; its generalized eigenvalues solve $\mathbf{B}\mathbf{x} = \lambda\mathbf{A}\mathbf{x}$	Definition 12.4.1

23.0.9 Orders, convexity and non-negative matrices

Symbol	Meaning	Defined at
$\mathbf{x} \geq \mathbf{0}$, $\mathbf{A} \geq 0$, $\mathbf{A} > 0$	the **entrywise** order; a positive matrix has every entry positive	Definition 18.1.1
$\mathbb{R}^m_{\geq 0}$	the non-negative orthant	Definition 17.5.1
$\mathbf{x} \prec \mathbf{y}$, $\mathbf{x} \prec_w \mathbf{y}$, $\mathbf{x}^{\downarrow}$	majorization, weak majorization, decreasing rearrangement	Definition 16.8.1
$\operatorname{conv} S$, $\operatorname{aff} S$	convex hull; affine hull, a coset of a subspace	Definition 17.1.4, Definition 17.1.5
$[\mathbf{x}, \mathbf{y}]$	the segment from $\mathbf{x}$ to $\mathbf{y}$	Definition 17.1.1
Δ_n	standard simplex: n non-negative weights adding to 1	Definition 17.1.2
$\operatorname{int}(S)$, $\overline{S}$	interior and closure in a finite-dimensional real space	Definition 17.3.2, Definition 17.1.6
$P_C(\mathbf{x})$, $d(\mathbf{x}, C)$	nearest point of a closed convex set, and the distance to it	Theorem 17.3.1
p_K, h_K, K°	gauge, support function and polar set of a convex set	Definition 17.4.1, Definition 17.4.2, Definition 17.4.3
K^*	dual cone, inside V itself	Definition 17.5.3
$\operatorname{cone}(\mathbf{a}_1, \ldots, \mathbf{a}_m)$	finitely generated cone	Definition 17.5.2
$\operatorname{epi} f$	epigraph, $\{(\mathbf{x}, s) : s \geq f(\mathbf{x})\}$	Definition 17.10.1
$\operatorname{ext} C$	extreme points of a convex set	Definition 17.8.1, Definition 17.8.2
$\mathcal{D}_n$, Ω_n	real density matrices; doubly stochastic matrices	Definition 17.8.3, Definition 17.8.4
$v(\mathbf{A})$	value of the matrix game with payoff matrix $\mathbf{A}$	Definition 17.7.2, Definition 17.7.1
$\mathbf{A} \# \mathbf{B}$	geometric mean of two positive definite matrices	Definition 20.11.1
$L_f(t_1, \ldots, t_n)$	Loewner matrix of divided differences	Definition 20.9.2, Definition 20.9.1
$G(\mathbf{A})$	directed graph of a square matrix: an edge $j \to i$ when $a_{ij} \neq 0$	Definition 18.2.1
irreducible, primitive	no proper invariant coordinate subspace; some power is positive	Definition 18.2.3, Definition 18.5.1
h, $\omega = e^{2\pi i/h}$	period of an irreducible non-negative matrix, and the root of unity it names	Definition 18.5.2
$\underline{r}_{\mathbf{A}}(\mathbf{x})$, $\overline{r}_{\mathbf{A}}(\mathbf{x})$	lower and upper Collatz–Wielandt functions; the bars are not conjugation	Definition 18.4.1
Perron root and vectors	$\rho(\mathbf{A})$, the right vector $\mathbf{v} > \mathbf{0}$ with $\mathbf{1}^\top \mathbf{v} = 1$, the left vector $\mathbf{w}$ with $\mathbf{w}^\top \mathbf{v} = 1$	Definition 18.1.2, Definition 18.3.1
$\mathbf{Q}$, $\mathbf{R}$, $\mathbf{N}$	transient block, absorbing block and fundamental matrix of an absorbing chain	Definition 18.6.1
$\mathbf{G}$, $\mathbf{H}$, α	Google matrix, raw link matrix, damping factor	Definition 18.8.2, Definition 18.8.1
$\mathbf{K}_n$	the second-difference matrix, a non-singular M-matrix	Definition 18.9.2, Definition 18.9.1
stochastic matrix, steady state	column sums 1 and non-negative entries; a fixed probability vector	Definition 8.11.1, Definition 8.11.2

23.0.10 Algebras, groups and representations

Symbol	Meaning	Defined at
A, 1_A	an associative algebra over F and its unit; plain italic, never bold	Definition 13.12.1
$\mathcal{T}_n$, $\mathcal{N}$	the upper triangular matrices in $M_n(F)$; its ideal of strictly upper triangular ones	Example (Six subalgebras)
$F\langle S\rangle$	the subalgebra generated by a set: the span of the words in S	Definition 22.1.4
$F[T]$, $F[\mathbf{A}]$	the algebra of polynomials in one operator or matrix, of dimension $\deg m_T$	Proposition 22.1.2
$F[G]$, δ_g	group algebra of a finite group and its basis of point masses	Definition 22.1.5
L_a	left multiplication by a; the regular representation is $a \mapsto L_a$	Theorem 22.1.3
S', S'', $Z(A)$	commutant, double commutant, center	Definition 22.1.6, Proposition 22.1.5
C_j, L_W, R_U	the column ideals of $M_n(F)$, and the left and right ideals of a subspace	Definition 22.2.1, Proposition 22.2.4
$A/\mathcal{I}$, π	quotient algebra by a two-sided ideal, and the quotient homomorphism	Definition 22.2.2
$\operatorname{rad} A$	radical of an algebra: killed by every irreducible representation	Definition 22.3.5
$a\mathbf{v}$, an A-space	an action of A on V, that is a homomorphism $A \to \operatorname{End}(V)$	Definition 22.3.2
simple, semisimple	an A-space with no proper non-zero invariant subspace; a direct sum of such	Definition 22.3.3, Definition 22.3.4
$\operatorname{End}_A(V)$, $\operatorname{Hom}_A(V,W)$	equivariant maps, $f(a\mathbf{v}) = af(\mathbf{v})$; the subscript is never dropped	Definition 22.4.1
$A(\mathcal{F})$	the subalgebra generated by a family of operators	Lemma 22.4.2
$\mathbf{v}\varphi$	the rank-one operator $\mathbf{x} \mapsto \varphi(\mathbf{x})\mathbf{v}$	Theorem 22.5.2
e_i	orthogonal idempotents of a product of algebras: italic, never bold	Definition 22.6.1
ρ, $\chi_\rho(g) = \operatorname{tr}\rho(g)$	a representation of a group and its character	Definition 22.7.1, Definition 22.8.2
irreducible, equivalent	no proper non-zero subrepresentation; conjugate by one isomorphism	Definition 22.7.4, Definition 22.7.3
$\mathrm{Cl}(G)$, $\langle f, f'\rangle$	class functions on G, and their averaged inner product	Definition 22.8.3, Definition 22.8.4
V^G	the fixed space of a representation	Lemma 22.8.4
$\langle g\rangle$, $G \times H$	the cyclic subgroup generated by g; a direct product of groups	Definition 22.9.1, Definition 22.9.2
$\widehat{G}$, $\widehat{f}$, ev_g	dual group of a finite abelian group, Fourier transform, evaluation at g	Definition 22.9.3, Definition 22.9.5
$\mathbf{U}$	character matrix, $(\mathbf{U})_{mj} = \chi_j(g_m)/\sqrt{n}$, indices from 0	Definition 22.9.4
$\mathbf{C}$, $\mathbf{F}$	circulant matrix; the Fourier matrix	Definition 11.9.1, Theorem 11.9.3
$\mathbf{c} * \mathbf{d}$	cyclic convolution, subscripts read modulo n	Definition 11.9.1

Symbol	Meaning	Defined at

23.0.11 Geometry

Symbol	Meaning	Defined at
$\mathcal{A}, \mathcal{B}, \mathcal{C}$	affine spaces, plain calligraphic	Definition 21.1.1
P, Q, R, $\overrightarrow{PQ}$, $P + \mathbf{v}$	points of an affine space, **not bold**; the vector between two points; translation of a point	Definition 21.1.1
$\mathbb{A}^n(F)$	affine n-space: F^n with its origin forgotten	Definition 21.1.1
θ_O	the choice-of-origin bijection $\mathcal{A} \to V$, $P \mapsto \overrightarrow{OP}$	Proposition 21.1.3
$\vec{f}$, $\widehat{f}$	linear part of an affine map; its block matrix, homogenizing coordinate **last**	Theorem 21.1.5, Proposition 21.1.7
$\mathrm{Aff}(\mathcal{A})$, $\tau_{\mathbf{v}}$	the affine group, and translation by $\mathbf{v}$	Theorem 21.1.6
$\vec{A}$, $A \vee B$, $A \parallel B$	direction space of a flat; the join; parallelism	Definition 21.2.1, Definition 21.2.2, Definition 21.2.3
P_J	the face of a polyhedron cut out by making the rows $i \in J$ tight	Proposition 21.3.1, Definition 21.3.1
$\mathrm{E}(n)$, $t_{\mathbf{b}}$, $\mathrm{Fix}(f)$	the Euclidean group, translation by $\mathbf{b}$, fixed set of a motion	Definition 21.4.1
$\mathbf{R}_\theta$, $\mathbf{M}_\theta$	plane rotation and plane reflection matrices	Theorem 10.7.5
$\widetilde{\mathbf{A}}$, $\tilde{\mathbf{x}}$	big matrix and big vector of a quadric, with $Q(\mathbf{x}) = \tilde{\mathbf{x}}^\top \widetilde{\mathbf{A}} \tilde{\mathbf{x}}$	Definition 21.5.1
$\mathbb{P}(V)$, $\mathbb{P}^n(F)$	projective space of V, of dimension $\dim V - 1$; $\mathbb{P}(F^{n+1})$	Definition 21.6.1
$[\mathbf{x}] = [x_0 : \cdots : x_n]$	homogeneous coordinates; coordinates run from 0	Definition 21.6.2
U_0, U_j, H_∞, ι	the standard affine chart, the other charts, the hyperplane at infinity, the chart bijection	Theorem 21.6.2
$S \vee T$, $S \cap T$	join and meet of projective subspaces	Proposition 21.6.5, Definition 21.6.3
$[T]$, $[\mathbf{A}]$	the projectivity induced by an isomorphism or an invertible matrix	Definition 21.7.1
$\mathrm{PGL}(V)$, $F^\times$	projective linear group; the multiplicative group of the field	Theorem 21.7.3
$(A, B; C, D)$	cross-ratio of four points: itself a point of $\mathbb{P}^1(F)$, not a scalar	Definition 21.7.3
S^0	projective annihilator, Chapter 4's U^0 read in $\mathbb{P}(V^*)$	Theorem 21.8.3, Definition 21.8.1
$\mathbf{o}$	a chosen representative vector of a projective point	Lemma 21.9.1
$Z(q)$, P^β	zero set of a quadratic form; the polar of a point with respect to a conic	Definition 21.10.1, Definition 21.10.2
p_{ij}, $[L]$, $\mathcal{K}$	Plücker coordinates of a line, the point they form, and the Klein quadric	Definition 21.10.3
vol	volume: of a parallelepiped it is $\lvert\det\rvert$; extended to k-dimensional volume	Definition 6.9.1, Definition 12.3.1

Symbol	Meaning	Defined at
$(\operatorname{In}\mathbf{A}, \operatorname{In}\widetilde{\mathbf{A}})$	the pair of inertia triples of a real quadric, an invariant of its affine equivalence class	Definition 21.5.2, Definition 16.10.1

23.0.12 Computation

Symbol	Meaning	Defined at
u, fl, $\mathcal{R}$, δ	unit roundoff, the rounding map, the representable numbers, one rounding	Definition 23.1.1
$\gamma_k = ku/(1-ku)$	the accumulated-rounding constant	Lemma 23.1.1
$\widehat{\mathbf{x}}$, $\Delta\mathbf{A}$	a computed object; a data perturbation produced by an algorithm	Definition 23.1.2, Definition 23.1.3
flop, g_n	one arithmetic operation; the growth factor of elimination	Definition 23.2.1, Definition 23.13.1
$\mathcal{K}_k(\mathbf{A}, \mathbf{b})$, $\theta_1, \dots, \theta_k$	Krylov space $\operatorname{span}(\mathbf{b}, \mathbf{Ab}, \dots, \mathbf{A}^{k-1}\mathbf{b})$; the Ritz values from it	Definition 23.6.1, Definition 23.6.2
Ł, Ł_0, $\mu_2(\text{Ł})$	graph Laplacian $\mathbf{D}-\mathbf{A}$, the reduced Laplacian, the Fiedler value	Definition 23.11.1, Definition 23.11.2
$\mathbf{X}$, $\mathbf{X}_c$, $\mathbf{S}$	data matrix, its centered form, the sample covariance	Definition 23.10.1, Definition 23.10.2
$\mathbf{M}$, $\mathbf{K}$, ω_j	mass matrix, stiffness matrix, natural frequencies	Definition 23.9.2
$\mathbf{W}_n$, $\mathbf{P}_n$, $\mathbf{D}_m$, $\mathbf{B}_n$	unnormalized transform matrix, even-odd permutation, twiddle matrix, butterfly	Definition 23.12.1, Definition 23.12.2
ω	the exponent of matrix multiplication	Definition 23.13.2

23.0.13 Where the book overrides itself

Twenty-four chapters do not have twenty-four alphabets. Several letters carry more than one meaning, and a few English words carry more than one definition. In every case the local meaning is declared where it is used, and in every case there is a tell — an argument, a subscript, a typeface — that decides which one is meant. The rows below list the clashes worth knowing before you meet them.

Symbol or word	The meanings	How to tell
$\mathbf{U}$	a generic upper triangular matrix (Definition 0.9.5, Definition 2.6.1); a unitary matrix, in the Schur and singular value factorizations (Corollary 11.1.3, Definition 12.8.1); the character matrix of a finite abelian group (Definition 22.9.4)	the chapter: triangular in Chapters 2 and 22, unitary from Chapter 11 on, the character matrix only in Chapter 22 §09

Symbol or word	The meanings	How to tell
$\mathbf{V}$	the right factor of a singular value decomposition, $\mathbf{A} = \mathbf{U\Sigma V}^*$ (Theorem 12.8.1); the Vandermonde matrix $\mathbf{V}(x_1, \ldots, x_n)$ (Theorem 6.8.1); one of the two matrices invertible over $F[x]$ in $\mathbf{B} = \mathbf{UAV}$ (Definition 9.7.2). Plain V is a vector space	the Vandermonde matrix always carries its nodes; the typeface for the space, and Chapter 9 §07 is the one place $\mathbf{V}$ is invertible only over $F[x]$
irreducible	a polynomial with no non-trivial factorization (Definition 5.3.1); a non-negative matrix with no invariant coordinate subspace (Definition 18.2.3); an A-space or a representation with no proper non-zero invariant subspace (Definition 22.3.3, Definition 22.7.4)	what the word is applied to. The three notions are unrelated
e_i versus $\mathbf{e}_i$	italic e_i is an idempotent of a product of algebras (Definition 22.6.1); bold $\mathbf{e}_i$ is the i-th standard basis vector (Example (Standard Bases))	the typeface, and that is the whole reason Chapter 22 chose italic
$\mathbf{G}$	Gram matrix (Definition 10.2.3); Givens rotation $\mathbf{G}(i, j; c, s)$ (Definition 10.8.2); Google matrix (Definition 18.8.2); the alternating Gram matrix of the Plücker form (Definition 21.10.3). Plain $G(\mathbf{A})$ is the directed graph of a matrix (Definition 18.2.1)	the Givens rotation always carries its four arguments; the graph is plain italic with its matrix in brackets
$\mathbf{H}$, $\mathbf{K}$	Hessian $\mathbf{H}_f(\mathbf{a})$ (Definition 13.6.2); Householder reflection $\mathbf{H}_\mathbf{w}$ (Definition 10.8.1); the Hermitian and skew parts of a matrix (Lemma 19.2.3); the raw link matrix (Definition 18.8.1); the second-difference matrix $\mathbf{K}_n$ (Definition 18.9.2); the stiffness matrix (Definition 23.9.2). Calligraphic $\mathcal{K}_k(\mathbf{A}, \mathbf{b})$ is a Krylov space (Definition 23.6.1) and $\mathcal{K}$ the Klein quadric (Definition 21.10.3); blackboard $\mathbb{H}$ is the quaternions (Definition 13.12.3)	the Hessian and the Householder reflection always carry their argument, the second-difference matrix always its size $\mathbf{K}_n$, the Krylov space its subscript and arguments
Ł	the lower triangular factor of an elimination (Definition 2.6.1); the graph Laplacian (Definition 23.11.1); the Lax matrix (Definition 23.8.1). Plain L_a is left multiplication in an algebra (Theorem 22.1.3) and L_f a Loewner matrix (Definition 20.9.2); calligraphic $\mathcal{L}(V, W)$ is a space of maps (Definition 3.4.1)	Chapter 23 §§08 and 11 each declare their use at the head of the section; the plain letters carry a subscript
$\mathbf{R}$, r	the $\mathbf{R}$ of a QR factorization; the plane rotation $\mathbf{R}_\theta$ (Theorem 10.7.5); the rotation through $2\pi/n$ in Chapter 22; the absorbing block of a Markov chain (Definition 18.6.1). Plain $R_\mathbf{A}(\mathbf{x})$ is the Rayleigh quotient (Definition 16.1.1) and $r_i(\mathbf{A})$ a Gershgorin radius (Definition 19.1.1)	the Rayleigh quotient is plain italic and takes a vector; the Gershgorin radius is plain and takes an index

Symbol or word	The meanings	How to tell
Q	the orthogonal factor of a QR factorization; the orthogonal linear part of a Euclidean motion (Definition 21.4.1); the quarter turn in Chapter 22; the transient block of an absorbing chain (Definition 18.6.1). Blackboard $\mathbb{Q}$ is the rationals (Definition 0.3.1)	the chapter, and the blackboard face for the field
S, $\mathcal{S}$	a congruence or a similarity matrix; a Schur complement in Chapter 23 §02; the sample covariance (Definition 23.10.2); the cyclic shift in Chapter 11 §09. Calligraphic $\mathcal{S}_{\mathbf{A},\mathbf{B}}$ is the Sylvester operator (Definition 11.10.1)	each section of Chapter 23 says which it means; the Sylvester operator carries both its matrices
N, $\mathcal{N}$	the fundamental matrix $(\mathbf{I}-\mathbf{Q})^{-1}$ of an absorbing chain (Definition 18.6.1); an incidence matrix, with $Ł = \mathbf{N}\mathbf{N}^\top$ (Definition 2.7.1); the strictly upper triangular matrices $\mathcal{N}$ (Example (Six subalgebras)). Blackboard $\mathbb{N}$ is the natural numbers	the calligraphic face for the algebra, the blackboard face for the number set
J	the all-ones matrix (Example (Orthogonally diagonalizing a 3 by 3 matrix)); the Jordan block $\mathbf{J}_k(\lambda)$ (Definition 9.3.1)	the Jordan block always carries its size and its eigenvalue
C	the companion matrix $\mathbf{C}(p)$ (Definition 9.5.3); the real Jordan block $\mathbf{C}_k(\lambda)$ (Definition 9.4.1); a circulant (Definition 11.9.1). Plain C and C_b^a are contractions (Definition 14.4.1) and C_{ij} a cofactor (Definition 6.6.1); blackboard $\mathbb{C}$ is the complex numbers	the companion matrix always carries its polynomial, the Jordan blocks their size and eigenvalue; a bare **C** in Chapter 22 is a circulant
W, W	the Wielandt matrix $\mathbf{W}_n$ (Theorem 18.5.6); the unnormalized transform matrix $\mathbf{W}_n$ of Chapter 23 §12; the accumulated orthogonal factor $\mathbf{W}_k$ of Chapter 23 §08. Plain W is a subspace, $W(\mathbf{A})$ the numerical range (Definition 19.2.1), and W_n the zero-sum matrices of Chapter 18 §07 (Lemma 18.7.1)	the numerical range always carries its matrix as an argument; the subspace never carries one
Θ, θ	the isomorphism $\mathbb{C} \to \mathbb{R}^2$ (Example (The Standard Isomorphisms)); the basis-dependent $V \to V^*$ (Theorem 4.3.2); the natural isomorphism $V^* \otimes W \to \mathcal{L}(V,W)$ (Theorem 14.3.9); the diagonal matrix of principal angles (Definition 19.8.1). Lowercase: the angle between vectors (Definition 10.1.5), the choice-of-origin map θ_O (Proposition 21.1.3), the Ritz values $\theta_1, \dots, \theta_k$ (Definition 23.6.2)	the principal-angle Θ appears only inside $\sin\Theta$ and $\cos\Theta$; lowercase θ is an angle unless the section says otherwise, and the choice-of-origin map carries the point O
Π, π	bold $\mathbf{\Pi}$ is the limit of a convergent stochastic matrix (Theorem 9.10.4); plain Π is a plane in Chapter 21 §§04, 08, 09 and the quotient map $\mathrm{GL}(V) \to \mathrm{PGL}(V)$ in §07; π is the quotient map $X \to X/\!\sim$ of a set (Definition 0.5.5), a quotient homomorphism of algebras (Definition 22.2.2) and, locally, a slot projection	the typeface, and that no section of Chapter 21 uses both meanings

Symbol or word	The meanings	How to tell
Φ, Ψ	a symmetric gauge function and its dual (Definition 20.3.1, Definition 20.3.3); the two isomorphisms of Chapter 22 §09 (Definition 22.9.5)	the argument: a gauge eats a real vector, Chapter 22's maps eat an element of a group algebra
Ω, ω	plain Ω_n is the doubly stochastic matrices (Definition 17.8.4), bold $\mathbf{\Omega}_{2m}$ the standard alternating matrix (Definition 13.10.2). Lowercase ω is a root of unity (Definition 18.5.2, Definition 23.12.1), an angular frequency (Definition 23.9.2), the exponent of matrix multiplication (Definition 23.13.2), and a differential form being wedged (Definition 14.10.1)	the typeface for Ω; for ω, the section, each of which declares its use
ρ	spectral radius (Definition 15.4.1); a representation of a group or an algebra (Definition 22.7.1)	the argument: a matrix for the radius, a group element for the representation
σ	a permutation (Definition 6.3.2); a singular value $\sigma_i(\mathbf{A})$ (Definition 12.8.1)	the singular value always carries an index and a matrix
λ, μ	a scalar or an eigenvalue throughout; also the linear-part homomorphism $\mathrm{E}(n) \to \mathrm{O}(n)$ (Definition 21.4.1) and the Fiedler value μ_2 (Definition 23.11.2)	Chapter 21 §04 is the one place λ is not a scalar, and it says so
$\lvert\cdot\rvert$	modulus of a complex number (Definition 0.6.2); cardinality of a set; the matrix absolute value $(\mathbf{A}^*\mathbf{A})^{1/2}$ (Definition 12.2.1); the **entrywise** absolute value in Chapter 18 (Definition 18.1.1)	what sits inside. Chapter 18 states its override, and the Chapter 12 meaning does not appear there
Λ	plain $\Lambda^k V$ is an exterior power (Definition 14.8.2); bold $\mathbf{\Lambda}(\lambda)$ is a rotation-scaling block (Definition 9.4.1)	the typeface, and the block always carries its eigenvalue
δ	Kronecker delta δ_{ij} (Definition 0.9.3); a point mass δ_g in a group algebra (Definition 22.1.5); a basis element δ_s of a free vector space (Definition 14.2.3); one rounding error (Definition 23.1.1)	the Kronecker delta always carries two **numerical** subscripts
$\perp$	orthogonal complement $U^\perp$ (Definition 10.3.1); the complement $U^{\perp_\beta}$ for a bilinear form (Definition 13.1.3); orthogonal direct sum $U \perp W$ of a form (Definition 13.7.3); a polarity $S^\perp$ in projective space (Theorem 21.8.3)	the unadorned $U^\perp$ is always the inner-product one
$\cong$, $\sim$, $\simeq$, $\approx$	isomorphic spaces (Definition 3.5.3) or, between spaces carrying forms, isometric (Definition 13.8.1); similar matrices (Definition 3.7.2); congruent matrices (Definition 13.2.1); equivalent over $F[x]$ (Definition 9.7.2), or "approximately equal" in prose	what stands on either side; the four relation symbols are never interchanged

Symbol or word	The meanings	How to tell
brackets	$[\mathbf{v}]_{\mathcal{B}}$ a coordinate vector (Definition 1.5.2); $[T]^{\mathcal{C}}_{\mathcal{B}}$ a matrix of a map (Definition 3.6.1); $[\mathbf{A}, \mathbf{B}]$ a commutator (Definition 7.5.1); $[\mathbf{x}, \mathbf{y}]$ a segment (Definition 17.1.1); $[\mathbf{x}]$ a projective point (Definition 21.6.2) and $[T]$ a projectivity (Definition 21.7.1); $F[x]$ and $F[G]$ rings and algebras (Definition 0.8.2, Definition 22.1.5)	the number of arguments and whether they are bold: a segment takes two bold vectors, a commutator two bold matrices
T	a linear map throughout; the transpose $\mathbf{A}^\top$; Chebyshev polynomials T_n (Definition 23.7.4); the tensor algebra $\mathrm{T}(V)$ (Definition 14.6.2) and mixed tensors $T^p_q(V)$ (Definition 14.4.2); a T-transform (Definition 20.1.1)	the tensor algebra is upright and takes a space; the Chebyshev polynomial and the T-transform carry subscripts
P, p	orthogonal projection P_U (Definition 10.3.2); Legendre polynomials P_n (Definition 10.10.1); a point of an affine space (Definition 21.1.1); the nearest-point map P_C (Theorem 17.3.1); a face P_J (Proposition 21.3.1); the even-odd permutation $\mathbf{P}_n$ (Definition 23.12.2); characteristic polynomial p_T (Definition 6.10.1); a gauge p_K (Definition 17.4.1)	a subspace subscript means a projection, an integer subscript a polynomial; bold means a matrix
Z	the cyclic subspace $Z(\mathbf{v}; T)$ (Definition 9.5.1); the center $Z(A)$ of an algebra (Definition 22.1.6); the zero set $Z(q)$ of a quadratic form (Definition 21.10.1); a Z-matrix (Definition 18.9.1)	the argument decides: a vector and an operator, an algebra, or a form
$\mathbf{E}$, E	the perturbation in $\mathbf{A} + \mathbf{E}$; a matrix unit $\mathbf{E}_{ij}$ (Example (Standard Bases)); an elementary matrix (Definition 2.4.1); an eigenspace $E_\lambda(T)$ (Definition 8.2.2); the Euclidean group $\mathrm{E}(n)$ (Definition 21.4.1)	subscripts again: two indices give a matrix unit, an eigenvalue gives an eigenspace, a bare $\mathbf{E}$ is the perturbation
$\mathbf{D}$, D	a diagonal matrix (Definition 0.9.4); the elementary scaling $\mathbf{D}_i(c)$ (Definition 2.4.1); the twiddle matrix $\mathbf{D}_m$ (Definition 23.12.2); the degree matrix in $\mathbf{L} = \mathbf{D} - \mathbf{A}$ (Definition 23.11.1); a Gershgorin disc $D_i(\mathbf{A})$ (Definition 19.1.1); density matrices $\mathcal{D}_n$ (Definition 17.8.3)	the Gershgorin disc is plain italic, since the bold letter is a diagonal matrix
$\mathbf{M}$, M	a block matrix, as in the Schur complement $\mathbf{M}/\mathbf{A}$ (Definition 7.3.1); the mass matrix (Definition 23.9.2); the plane reflection $\mathbf{M}_\theta$ (Theorem 10.7.5); a minor M_{ij} (Definition 6.6.1); the space $M_n(F)$ (Definition 0.9.1); an M-matrix (Definition 18.9.2)	plain italic with two indices is a minor; $M_n(F)$ always carries its size and field
u	the unit roundoff (Definition 23.1.1); bold $\mathbf{u}$ is a vector	the typeface; Chapter 23 §01 warns about the pair
h	the period of an irreducible non-negative matrix (Definition 18.5.2); a support function h_K (Definition 17.4.2); a mesh width in Chapter 18 §09	the support function always carries its convex set

Symbol or word	The meanings	How to tell
simple	a simple algebra (Definition 22.3.1); a simple A-space (Definition 22.3.3); a simple eigenvalue, of multiplicity one (Definition 19.11.1); a simple tensor (Definition 14.2.2)	what the word is applied to
equivalent	equivalent matrices $\mathbf{B} = \mathbf{QAP}$ (Definition 3.8.1); equivalence over $F[x]$ (Definition 9.7.2); equivalent norms (Definition 15.2.1); equivalent representations (Definition 22.7.3); affine equivalence of quadrics (Definition 21.5.2)	the objects being compared
positive	$\mathbf{A} > 0$ entrywise, every entry positive (Definition 18.1.1); $\mathbf{A} \succ 0$ positive definite (Definition 12.1.1)	the symbol: $>$ is entrywise, $\succ$ is the Loewner order. A positive matrix need not be positive definite, nor conversely
radical, **contraction**	radical of a bilinear form (Definition 13.1.3) or of an algebra (Definition 22.3.5); contraction of tensor slots (Definition 14.4.1) or a matrix of norm at most one (Definition 20.8.1)	the argument, in both cases
signature	the pair (n_+, n_-), and also the single integer $n_+ - n_-$	Definition 13.5.1 says which is meant where the word appears
